# 4 Stemmers and a Funeral: Stemming in Hungarian at CLEF 2005 

Anna Tordai Maarten de Rijke<br>Informatics Institute, University of Amsterdam<br>Kruislaan 403, 1098 SJ Amsterdam<br>\{atordai,mdr\}@science.uva.nl

#### Abstract

We developed algorithmic stemmers for Hungarian and used them for the ad-hoc monolingual task for CLEF 2005. Our goal was to determine what degree of stemming would be the most effective. Although on average the stemmers didn't perform as well as the 4 -gram, we found that stemming over a broad range of suffixes especially on nouns is highly useful.

## 1 Introduction

In our participation in the CLEF ad-hoc task this year, we focused exclusively on monolingual retrieval for Hungarian. This is the first year Hungarian is part of CLEF, and it is an ideal opportunity to test our work on the effects of stemming in Hungarian. Previous work on languages that are morphologically richer than English, such as Finnish, indicate that there should be benefits from morphological analysis such as stemming, lemmatization, and compound analysis [4, 5, 6]. We have developed a number of suffix-stripping algorithms of varying impact, all focusing on inflectional suffixes. Our goal is to determine the degree of stemming that would prove beneficial for retrieval effectiveness in terms of both precision and recall. We expect to see improvements for recall for the stemmers, but in addition, we hope that our "light" stemmers keep precision at an acceptable level. The "heavy" stemmer we developed is also expected to improve recall, but hurt precision.

The paper is organized as follows. Section 2 describes the traits of the Hungarian language that are important from an information retrieval point of view. Section 3 contains a description of the algorithmic stemmers along with an evaluation. Section 4 describes the retrieval system we used. Section 5 concerns the experiments we performed, finally followed by a conclusion in Section 6

## 2 Hungarian Morphology

Hungarian is an agglutinative language remotely related to Finnish and Estonian, and a member of the Ob-Ugric languages [8]. The Hungarian language is highly inflectional, rich in compound words, and has an extensive inflectional and derivational morphology. To illustrate this, nouns have 16 to 24 cases depending
on the classification system. By adding person, number and possession, a single noun may have as many as 1400 forms [3]. Adjectives similarly may have around 2700 different forms. Verbs have fewer forms, with person, number, tense, transitivity adding up to 59 . These numbers merely illustrate the inflectional variety of the language.

Additionally, there is an extensive system of derivational suffixes, many of them changing the part of speech of a word.

Compound words are frequent in Hungarian, presenting an additional challenge for retrieval. Compound nouns can be formed by two nouns or a participle and a noun. Adjectives can also be formed by the combination of a noun and adjective. Compounding was not addressed at this time.

## 3 Algorithmic Stemmers

In this section we describe and evaluate the stemmers used in our retrieval experiments.

### 3.1 Description of the Stemmers

The stemmers were built in the Snowball language 11] and are rule-based stemmers focusing on inflectional suffixes in Hungarian. Using the Szeged Corpus [1], which is a collection of annotated texts ranging from novels, children's essays, legal texts, newspaper articles to computer books, we created a list of the most frequent types of morphosyntactic tags. This helped to determine which suffixes appear most often in the text and guided the construction of the stemmers.

We developed four types of stemmers:

- Light1 - handling frequent noun cases, plural and frequent owners.
- Light2 - handling all noun cases, plural and frequent owners.
- Medium - handling frequent noun cases, plural, frequent owners and frequent verb tenses.
- Heavy - handling most inflectional suffixes.

We will now discuss the stemmers in more detail.
The lightest stemmer, Light1, only handles 14 frequent noun cases, plural and the most frequent possessive cases. It is the least invasive stemmer but statistics suggest it might still have a significant impact. Of all the nouns in the Szeged corpus $26 \%$ were in uninflected form. The most frequent types of suffixes cover $36 \%$ of the nouns. These were the ones targeted by Light1 with the exception of the single letter suffix ' $k$ ' indicating plurality. Even without it, at least half of all nouns should be indexed in their stem form. Since adjectives have the same case, number and possession suffixes as nouns they also become stemmed along with numerals which also share a number of cases with nouns.

The second stemmer, Light2, is similar to Light1 except it handles 21 noun cases instead of just 14, also removing single letter suffixes such as the accusative
't' and superessive ' $n$ '. The Light1 and Light2 stemmers both take word length into account, making sure the remainder is at least a valid vowel-consonant combination.

The third stemmer, Medium, removes 12 frequent noun cases, plural, possession and combinations of ownership and plurality. It also handles frequent verb tense-person-number combinations as well as the degree of adjectives. In addition, suffixes forming ordinals and fractions out of numerals were also removed.

The last stemmer, Heavy, is the most aggressive, removing 21 noun cases, handling plurality and possession. For verbs it handles infinitive, indicative, conditional and subjunctive moods.

Unfortunately, there are a number of difficulties for the stemmers such as overstemming and homonymy. The overstemming of terms such as nemzet (nation) to the invalid nemz could be alleviated by an exceptions list containing frequent words. Homonymy, for instance with the term nevet meaning either 'to laugh' or the accusative form of 'name', can only be solved by looking at the context of the word.

### 3.2 Evaluating the Stemming Algorithms

The stemmers were evaluated both intrinsically and extrinsically. For the intrinsic evaluation, we used Paice's method based on error counting [9]. According to this method, two values determine the quality of a stemmer: understemming and overstemming. In order to determine these values, a list of words is separated into conceptual groups formed by semantically and morphologically related words. This is the target, and an ideal stemmer should conflate words to these conceptual groups.

The stemmers were used to stem the word list, and following the Paice method their correspondence to the conceptual groups was measured. This resulted in an understemming (UI) and overstemming measure (OI). To determine the general relative accuracy of the stemmers, we use a measure, called error rate relative to truncation, or ERRT. It is useful for deciding on the best overall stemmer in cases where one stemmer is better in terms of understemming but worse in terms of overstemming. To calculate the ERRT we created a baseline using length truncation by reducing the words in the world list to their $n$ first letters where $n$ was $9,10,11$ and 12 . The overstemming and understemming measure of these truncated lists defines the truncation line. The values of any reasonable stemmers are found between this line and the origin. Figure 1 shows the UI and OI values for each stemmer with the truncation line. Generally, the further the stemmer is from this line, the better it performs on the word lists. By drawing a line that passes through the origin, the datapoint identified by the pair (UI,OI) consisting of the stemmer's understemming and overstemming index, respectively, and that intersects the truncation line, we obtain the distances necessary to calculate the ERRT value of each stemmer. These are the distance from the origin to the stemmer's (UI,OI) divided by the distance from the origin to the intersection (with the truncation line). Low overstemming and understemming indexes are the desired feature in a stemmer. Stemmers that are closer to the
origin have lower UI and OI values which means the distance is also shorter. The 'best' stemmer would also have the lowest ERRT value compared to the rest.

Fig. 1. $U I \times O I$ plot with the $E R R T$ distances.
Table 1 contains the UI, OI and ERRT values for each of the four stemmers used. As expected, Light1, being the lightest stemmer, has the highest understemming index, while Heavy has the lowest value. The high value for understemming for Light1 indicates that it leaves many words unstemmed or just understemmed. The reverse is true for the overstemming index. The Medium stemmer has a lower understemming and higher overstemming index than Light2 which, at first sight, seems surprising. However, $54 \%$ of the words in the list are nouns, and since Light2 removes all noun cases just like the Heavy stemmer, but unlike Light1 and Medium, these scores make sense. The Medium stemmer focuses on some frequent noun cases and verbs. Verbs only form $23 \%$ of the word list so the reason for the somewhat unexpected values is simply due to the fact that the Medium stemmer stems fewer words than Light2. Overall, when it comes to stemming a word list, a stemmer handling all noun cases yields better results than one restricted to the most frequent noun cases and verb tenses. We suspect that this will apply to a lesser extent for retrieval as words are unique in the word list unlike in a normal corpus.

Table 1. Performance of the stemmers on the word-groups

|  | UI | OI | ERRT |
| :--- | :---: | :---: | :---: |
| Light1 | 0.75 | 0.0000028 | 0.81 |
| Light2 | 0.59 | 0.0000053 | 0.66 |
| Medium | 0.64 | 0.0000081 | 0.73 |
| Heavy | 0.53 | 0.0000134 | 0.65 |

The high ERRT value of Light1 indicates that although it has very low overstemming it leaves too many words understemmed making it too light. The same is true for the Medium stemmer, which loses out because it focuses on verbs even though there are fewer verbs than nouns in the word list. In this sense Light2 and Heavy come out as winners having the lowest ERRT values. What would this mean when used in an information retrieval setting? An analysis of English topics used in CLEF 2004 showed that after stopping over $65 \%$ of the words were nouns, only $10 \%$ verbs and $12 \%$ adjectives. A post submission analysis confirmed these findings for the 2005 Hungarian topics, with $60 \%$ of nouns, $23 \%$ adjectives and $17 \%$ verbs after stopping. Thus, even if a stemmer only concentrates on stemming nouns it should still have an impact on recall if not precision. Based on the ERRT values we expect the runs with Light2 and Heavy stemmers to yield a better recall than the other two stemmers and the baseline (no stemming at all). At the same time, precision will probably be negatively affected by the Heavy stemmer. These results suggest that the run with Light2 should have the highest recall and precision values since it has a low understemming ratio and should still stem a large percentage of words. Let's see.

## 4 Retrieval Setup

Now that we have described the stemmers that we have developed, we turn to our retrieval experiments. We used Lucene (off-the-shelf) for indexing and retrieval with a standard vector space model [7]. In addition, we used a stopword list which was created using the Szeged Corpus [1]. We created a list from the 300 most frequent words in the corpus. Numbers and homonyms were removed from the list and it was expanded with pronouns. The result was a list of 188 words ${ }_{\square}^{1}$ Both the index and queries were stopped. Diacritics were left untouched.

For more information on the ad-hoc track and the collection see [2, 10]. The document collection was encoded in UTF-8. As the Snowball stemmers were created for ISO Latin encoding, the entire collection was converted into ISO Latin 1 encoding without any loss of textual data.

## 5 The Experimental Results

### 5.1 Runs

The results of the official CLEF 2005 experiments have been discussed in our Working Notes [12]. We redid the same experiments with some small alterations such as changes in the stopword list and the separation of hyphenated words. We also performed some new experiments with 4- and 5-grams.

We extended the stopword list with extra terms that appear in practically every query and does not aid retrieval such as keressünk (let us search) and cikk (article) and their variations. This small change boosted the Mean Average Precision (MAP) and R-precision scores by an average of 0.5 .

Additionally we ran experiments with $n$-grams, this time testing 4 -grams and 5 -grams. The 4-gram run returned the highest MAP and R-precision of all the runs.

Analysis of the official runs [12] showed that some relevant documents weren't retrieved because the hyphenated terms in the query and documents weren't separated. To this end we performed a new experiment with the best stemmer, Heavy, where we separated hyphenated words in both document collection and queries. The MAP scores and precision scores improved somewhat as a result.

Table 2. Overview of MAP scores and $R$-precision scores for the runs. Best scores are in bold face

|  | MAP | R-prec \% | Relevant Docs Retrieved |
| :--- | :---: | :---: | :---: |
| Light1 | 0.2245 | 0.2477 | 74.7 |
| Light2 | 0.2911 | 0.3017 | 79.1 |
| Medium | 0.2417 | 0.2591 | 77.2 |
| Heavy | 0.2935 | 0.2921 | 79.8 |
| Heavy minus hyphen | 0.3099 | 0.3048 | 83.1 |
| Base | 0.1831 | 0.2096 | 62.9 |
| 4-Gram | $\mathbf{0 . 3 3 0 3}$ | $\mathbf{0 . 3 3 8}$ | $\mathbf{8 3 . 6}$ |
| 5-Gram | 0.3002 | 0.3057 | 82.4 |

As the results in Table 2 show, the 4-gram has the best performance with respect to MAP, R-precision and number of relevant documents retrieved. Amongst the algorithmic stemmers the Heavy stemmer has the highest MAP and Rprecision score followed closely by Light2. Medium scored lower and Light1 has the worst scores. Overall, when comparing the scores with the base run, any kind of stemming is better than no stemming at all.

Although the results are to some extent what we had expected, we need to perform a statistical test to determine if there is any significant difference between the methods and stemmers.

Since the data follows the normal distribution the t-tests we want to perform are valid. We wanted to know if the results of the four different stemming
algorithms was significantly different and whether the 4-gram performed significantly better than the Heavy stemmer. A repeated measures ANOVA (the between factor is the query) was performed and showed significant effects for the within factor stemmer for both MAP $(F=12.52, d f=5, p<0.01)$ and R-precision $(F=6.99, d f=5, p<0.05)$. There is a significant difference in the results of the four different stemmers. The results of the 4 - gram however did not differ significantly from the Heavy stemmer in both MAP $(t=1.131, d f=49$, $p>0.05)$ and R-precision $(t=1.298, d f=49, p>0.05)$.

### 5.2 Discussion

We examined four queries more closely to find out what the difference is between the performance of the 4 -gram and the Heavy stemmer. For the queries C285 and C298 the 4-gram outperformed the Heavy stemmer. In both cases the queries contained compound words such as abortuszellenes (anti-abortion) and atomerőmü (nuclear power station). The 4-gram found the relevant documents containing terms like abortusz (abortion) and erőmű (power station) while the Heavy run did not.

For the queries C272 and C273 the Heavy run outperformed the 4-gram run. In these cases the queries contained compound words like kelet-európai (Eastern European) and előélete ('previous life') as well as other frequent words that resulted in the low ranking of the relevant documents by the 4 -gram run.

## 6 Conclusion

We wanted to compare the performance of four different of algorithmic stemmers using two forms of evaluation. In Section 3 we found that the Light2 and Heavy stemmers worked best. This has been confirmed by the findings in Section 5 where we also determined that the Light2 and Heavy stemmers worked significantly better for retrieval than Medium and Light1. This effectively means that stemming nouns and with them adjectives (the two are linked because of similar morphology) is important and makes a difference for retrieval. The stemming of verbs doesn't seem to have a significant impact.

The 4-gram had the highest average scores of all the runs but we couldn't see significant difference between it and the best stemmer given the data. The 4-gram has an advantage over our algorithmic stemmers. It is a stemmer and compound splitter all rolled into one. However, as there is no control over what is being 'split' or stemmed' sometimes it can have negative effects on the ranking of the documents when compared with the stemmer.

The next step would be the development of a compound splitter to use in combination with the stemmers. There is also room for improvement with the stemmers themselves allowing them to handle more irregular forms and increase the number of correct stems.
