[1] Here we deviate from the CODATA recommendation in which g_e is defined as a negative number.

1

Quantum motion in a central potential field

The motion of particles in a *central* potential plays an important role in atomic and molecular physics. To understand the properties of the hydrogen atom we rely on careful analysis of the motion of the electron in the Coulomb field of the nucleus. Likewise, many properties related to interactions between atoms, such as collisional properties, can be understood by analyzing the relative atomic motion under the influence of central forces.

In view of the importance of central forces we summarize in this chapter the derivation of the Schrödinger equation for the motion of two particles, say of masses m_1 and m_2, interacting through a *central* potential $\mathcal{V}(r)$, $r = |\mathbf{r}_1 - \mathbf{r}_2|$ being the radial distance between the particles. For such potentials, purely depending on the *relative* distance between the particles, it is (in the absence of externally applied fields) practical to eliminate the center of mass motion of the pair and represent the relative motion by a single particle of *reduced mass* $m_r = m_1 m_2/(m_1+m_2)$ in the same potential field (see Appendix D.7). To further exploit the symmetry we can separate the radial motion from the rotational motion, obtaining the radial and angular momentum operators as well as the hamiltonian operator in spherical coordinates (Section 1.1). Knowing the Hamiltonian we can write down the Schrödinger equation (Section 1.2) and specializing to specific angular momentum values we obtain the *radial wave equation.* The radial wave equation is the central equation for the description of the radial motion associated with specific angular momentum states.

The approach just described amounts mathematically to the method of separation of variables for solving differential equations. This suggests to extend the discussion to cylindrical coordinates, as this opens - with little additional effort - a window onto related problems like quantization of electronic orbitals into Landau levels as well as the description of the flow fields of quantized vortices. In these cases the central potential is absent but the solutions are rotational in character; hence, show a form of central symmetry.

1.1 Hamiltonian

The classical Hamiltonian for the motion of a particle of (reduced) mass m_r in the central potential $\mathcal{V}(r)$ is given by the sum of the kinetic and potential energy,

$$H = \tfrac{1}{2} m_r \mathbf{v}^2 + \mathcal{V}(r), \tag{1.1}$$

where $\mathbf{v} = \dot{\mathbf{r}}$ is the velocity of the particle with $\mathbf{r}$ its position relative to the potential center. In the absence of externally applied fields $\mathbf{p} = m_r \mathbf{v}$ is the canonical momentum of the particle and the Hamiltonian can be written as[1]

$$H_0 = \frac{\mathbf{p}^2}{2m_r} + \mathcal{V}(r). \tag{1.2}$$

---

[1] In the presence of an external electromagnetic field the *non-relativistic* momentum of a *charged* particle of mass m and charge q is given by $\mathbf{p} = m\mathbf{v} + q\mathbf{A}$, with $m\mathbf{v}$ its *kinetic* momentum and $q\mathbf{A}$ its *electromagnetic* momentum.

To exploit the central symmetry we separate the radial motion from the angular motion by writing the Hamiltonian in the form (see Problem 1.1)

$$H_0 = \frac{1}{2m_r}\left(p_r^2 + \frac{\mathbf{L}^2}{r^2}\right) + \mathcal{V}(r) \quad (r \neq 0). \tag{1.3}$$

Here $p_r = \hat{\mathbf{r}} \cdot \mathbf{p}$ (see Fig. 1.1) is the *radial momentum*, with $\hat{\mathbf{r}} = \mathbf{r}/r$ the unit vector in radial direction, and $\mathbf{L} = \mathbf{r} \times \mathbf{p}$ the *orbital angular momentum* with respect to the potential center. As Eq. (1.3) is well-defined only *outside* the origin any result based on this expression should be tested for its validity at the origin.

Problem 1.1. Derive the vector relation (see also Appendix N).

$$(\hat{\mathbf{r}} \cdot \mathbf{p})^2 + (\hat{\mathbf{r}} \times \mathbf{p})^2 = \mathbf{p}^2. \tag{1.4}$$

Solution. In the Einstein notation with summation over repeating indices the cartesian components of $\hat{\mathbf{r}} \times \mathbf{p}$ are given by $(\hat{\mathbf{r}} \times \mathbf{p})_i = \varepsilon_{ijk}\hat{r}_j p_k$, where $i, j, k \in \{x, y, z\}$ and ε_{ijk} is the Levi-Civita tensor

$$\varepsilon_{ijk} = \begin{cases} 1 & \text{for } \textit{even} \text{ permutations of } x, y, z \\ 0 & \text{for } i = j \text{ or } i = k \text{ or } j = k \\ -1 & \text{for } \textit{odd} \text{ permutations of } x, y, z. \end{cases} \tag{1.5}$$

Using the summation convention, the contraction of the Levi-Civita tensor is given by

$$\varepsilon_{ijk}\varepsilon_{ilm} = \delta_{jl}\delta_{km} - \delta_{jm}\delta_{kl}.$$

Since $\mathbf{L}^2 = L_i L_i$ we obtain

$$\begin{aligned}(\hat{\mathbf{r}} \times \mathbf{p})^2 &= (\varepsilon_{ijk}\hat{r}_j p_k)(\varepsilon_{ilm}\hat{r}_l p_m) = (\delta_{jl}\delta_{km} - \delta_{jm}\delta_{kl})\,\hat{r}_j p_k \hat{r}_l p_m \\ &= (\hat{r}_j \hat{r}_j)(p_k p_k) - \hat{r}_j p_j \hat{r}_k p_k = \mathbf{p}^2 - (\hat{\mathbf{r}} \cdot \mathbf{p})^2 .\end{aligned}$$

□

1.1.1 Quantization of the Hamiltonian - basic commutation relations

The transition from classical mechanics to quantum mechanics is made by postulating that the dynamical variables for position and momentum correspond to the following *hermitian operators* in the *position representation*, $\mathbf{p} \to -i\hbar\boldsymbol{\nabla}$ and $\mathbf{r} \to \underline{\mathbf{r}}$.[1] This is known as *quantization by correspondence.* With this quantization rule, Eq. (1.2) becomes the quantum mechanical Hamiltonian and takes the familiar form of the *Schrödinger Hamiltonian* for a particle in a central field,

$$\mathcal{H}_0 = -\frac{\hbar^2}{2m_r}\Delta + \mathcal{V}(r). \tag{1.6}$$

Although the quantization went smoothly in this case, in general we should watch out for ambiguities in the application of the correspondence rules. For instance, whereas in classical mechanics the expressions $p_r = \hat{\mathbf{r}} \cdot \mathbf{p}$ and $p_r = \mathbf{p} \cdot \hat{\mathbf{r}}$ are equivalent this does not hold for $p_r = -i\hbar\,(\boldsymbol{\nabla} \cdot \hat{\mathbf{r}})$ and $p_r = -i\hbar\,(\hat{\mathbf{r}} \cdot \boldsymbol{\nabla})$ because $\hat{\mathbf{r}} = \mathbf{r}/r$ and $-i\hbar\boldsymbol{\nabla}$ do not commute.

Up to this point we did not make any choice of coordinate system (metric). To deal with non-commutativity for a given coordinate system the operator algebra has to be completed with commutation relations for the operators. In arbitrary *orthogonal* curvilinear coordinates $\mathbf{r} = \mathbf{r}(r_1, \cdots r_d)$ of a d-dimensional euclidean vector space the gradient vector is given by

$$\boldsymbol{\nabla} = \{h_1^{-1}\partial_1, \cdots, h_d^{-1}\partial_d\} = \hat{\mathbf{e}}_1 h_1^{-1}\partial_1 + \cdots + \hat{\mathbf{e}}_d h_d^{-1}\partial_d, \tag{1.7}$$

---

[1] Here we emphasized in the notation that $\underline{\mathbf{r}}$ is the position *operator* rather than the position $\mathbf{r}$. As this distinction rarely leads to confusion the underscore will be omitted in most of the text.

where the unit vectors are defined by $\hat{\mathbf{u}} \equiv \hat{\mathbf{e}}_u = \partial_u \mathbf{r}/|\partial_u \mathbf{r}|$ and the scale factors by $h_u \equiv |\partial_u \mathbf{r}|$, with $u \in \{r_1, \cdots r_d\}$. Here $\partial_u \equiv \partial/\partial r_u$ is a shorthand notation for the partial derivative operator. Note that $\partial_u \mathbf{r} = h_u \hat{\mathbf{u}}$.

In *cartesian* coordinates we have $\mathbf{r} = (r_1, \cdots r_d) = (x, y, z)$. As the radius vector is given by $\mathbf{r} = \hat{\mathbf{x}}x + \hat{\mathbf{y}}y + \hat{\mathbf{z}}z$ it follows that $\partial_x \mathbf{r} = \hat{\mathbf{x}}$, $\partial_y \mathbf{r} = \hat{\mathbf{y}}$, $\partial_z \mathbf{r} = \hat{\mathbf{z}}$ and $h_x = h_y = h_z = 1$. Note that the property $h_i = 1$, with $i \in \{1, \cdots, d\}$, is valid for an euclidean vector space of arbitrary dimension d. The commutation relations for the components of the operators r_i and $p_j = -i\hbar\partial_j$ are obtained by evaluating the action of the operator $[r_i, p_j]$ on a smooth test function of position $\phi(r_x, r_y, r_z)$,

$$[r_i, p_j]\,\phi = -i\hbar\,(r_i\partial_j - \partial_j r_i)\,\phi = -i\hbar\,(r_i\partial_j\phi - r_i\partial_j\phi - \phi\delta_{ij}) = i\hbar\delta_{ij}\phi. \tag{1.8}$$

Thus we derived the commutation relations

$$[r_i, p_j] = i\hbar\delta_{ij}. \tag{1.9}$$

These commutation relations hold for cartesian coordinates. In general, the direction of the unit vectors depends on position ($h_i \neq 1$) and the commutation relations *do not have this simple form.*

A consequence of the commutation relations (1.9) is that $\mathbf{r}$ and $\mathbf{p}$ do not commute with the Hamiltonian $\mathcal{H}_0$: for $\mathbf{p}$ we have $[p_i, \mathcal{H}_0] = [p_i, \mathcal{V}(r)] \neq 0$, for $\mathbf{r}$ we find an important relation between $\mathbf{p}$ and $\mathbf{r}$

$$[r_i, \mathcal{H}_0] = \left[r_i, \mathbf{p}^2/2m_r\right] = i(\hbar/m_r)p_i, \tag{1.10}$$

which can be written in the form

$$\mathbf{p} = -i\,(m_r/\hbar)\,[\mathbf{r}, \mathcal{H}_0]\,. \tag{1.11}$$

1.1.1.1 Laplacian in spherical coordinates

To explore the central symmetry of our problem we wish to write the laplacian from the Schrödinger Hamiltonian in *spherical coordinates* $\{r, \theta, \phi\}$. The relation between the cartesian coordinates and the spherical coordinates of a point $\mathbf{P} = \mathbf{P}(x, y, z) = \mathbf{P}\,(r, \theta, \phi)$ is given by (see Fig. 1.1)

$$x = r\sin\theta\cos\phi,\;\; y = r\sin\theta\sin\phi,\;\; z = r\cos\theta. \tag{1.12}$$

Using $\partial_a \mathbf{P} = h_a \hat{\mathbf{a}}$, with $a \in (\{r, \theta, \phi\}$, the angular dependence of the unit vectors is given by[1]

$$\hat{\mathbf{r}} = \hat{\mathbf{x}}\sin\theta\cos\phi + \hat{\mathbf{y}}\sin\theta\sin\phi + \hat{\mathbf{z}}\cos\theta \tag{1.13a}$$

$$\hat{\boldsymbol{\theta}} = \hat{\mathbf{x}}\cos\theta\cos\phi + \hat{\mathbf{y}}\cos\theta\sin\phi - \hat{\mathbf{z}}\sin\theta \tag{1.13b}$$

$$\hat{\boldsymbol{\phi}} = -\hat{\mathbf{x}}\sin\phi + \hat{\mathbf{y}}\cos\phi. \tag{1.13c}$$

Using $\mathbf{P} = \hat{\mathbf{r}}r = \mathbf{r}$ we calculate $h_r = |\partial\mathbf{r}/\partial r| = 1$, $h_\phi = |\partial\mathbf{r}/\partial\phi| = r(\sin^2\theta\sin^2\phi + \sin^2\theta\cos^2\phi)^{1/2} = r\sin\theta$ and $h_\theta = |\partial\mathbf{r}/\partial\theta| = r(\cos^2\theta\cos^2\phi + \cos^2\theta\sin^2\phi + \sin^2\theta)^{1/2} = r$.

Hence, in spherical coordinates the gradient operator (1.7) becomes

$$\boldsymbol{\nabla} = \hat{\mathbf{r}}\,\partial_r + \hat{\boldsymbol{\theta}}\frac{1}{r}\partial_\theta + \hat{\boldsymbol{\phi}}\frac{1}{r\sin\theta}\partial_\phi. \tag{1.14}$$

Evaluating the inner product $\boldsymbol{\nabla}\cdot\boldsymbol{\nabla}$ we obtain for the Laplace operator (see Problem 1.2)

$$\Delta = \frac{\partial^2}{\partial r^2} + \frac{2}{r}\frac{\partial}{\partial r} + \frac{1}{r^2\sin\theta}\frac{\partial}{\partial\theta}\sin\theta\frac{\partial}{\partial\theta} + \frac{1}{r^2\sin^2\theta}\frac{\partial^2}{\partial\phi^2}. \tag{1.15}$$

---

[1] In these lecture notes we use interchangeable notations for the radial unit vector: $\hat{\mathbf{r}} \equiv \Omega \equiv (\theta, \phi)$.

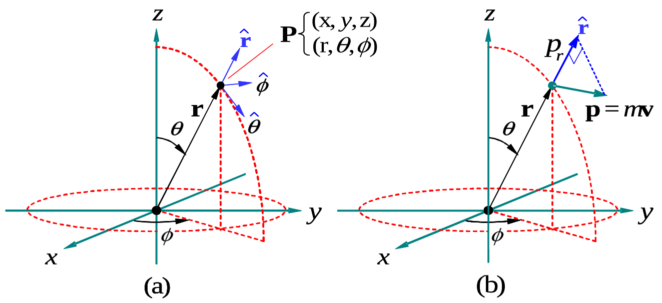

Figure 1.1: Illustration of spherical coordinates of a point $\mathbf{P} = \mathbf{P}(x, y, z) = \mathbf{P}\,(r, \theta, \phi)$: (a) unit vector convention; (b) vector diagram indicating the direction $\hat{\mathbf{r}}$ and amplitude p_r of the radial momentum vector.

Problem 1.2. Derive the expression (1.15) for the laplacian in spherical coordinates.

Solution. Starting from the vector expression (1.14) for the gradient operator the laplacian is obtained by evaluating the inner product

$$\begin{aligned}\boldsymbol{\nabla}\cdot\boldsymbol{\nabla}\psi = \hat{\mathbf{r}}\cdot\left(\partial_r\hat{\mathbf{r}}\,\partial_r + [\partial_r\hat{\boldsymbol{\theta}}]\frac{1}{r}\partial_\theta + [\partial_r\hat{\boldsymbol{\phi}}]\frac{1}{r\sin\theta}\partial_\phi\right)\psi \\ + \frac{1}{r}\hat{\boldsymbol{\theta}}\cdot\left([\partial_\theta\hat{\mathbf{r}}]\partial_r + \partial_\theta\hat{\boldsymbol{\theta}}\frac{1}{r}\partial_\theta + [\partial_\theta\hat{\boldsymbol{\phi}}]\frac{1}{r\sin\theta}\partial_\phi\right)\psi \\ + \frac{1}{r\sin\theta}\hat{\boldsymbol{\phi}}\cdot\left([\partial_\phi\hat{\mathbf{r}}]\partial_r + [\partial_\phi\hat{\boldsymbol{\theta}}]\frac{1}{r}\partial_\theta + \partial_\phi\hat{\boldsymbol{\phi}}\frac{1}{r\sin\theta}\partial_\phi\right)\psi.\end{aligned}$$

Here we dismissed many terms that yield zero due to the orthogonality of the unit operators. Using $\partial_r\hat{\mathbf{r}} = \partial_r\hat{\boldsymbol{\theta}} = \partial_r\hat{\boldsymbol{\phi}} = 0$ and $\partial_\theta\hat{\mathbf{r}} = \hat{\boldsymbol{\theta}}$, $\partial_\theta\hat{\boldsymbol{\theta}} = -\hat{\mathbf{r}}$, $\partial_\theta\hat{\boldsymbol{\phi}} = 0$ and $\partial_\phi\hat{\mathbf{r}} = \hat{\boldsymbol{\phi}}\,\sin\theta$, $\partial_\phi\hat{\boldsymbol{\theta}} = \hat{\boldsymbol{\phi}}\,\cos\theta$, $\partial_\phi\hat{\boldsymbol{\phi}} = -\,\hat{\mathbf{r}}\sin\theta - \hat{\boldsymbol{\theta}}\cos\theta$ the expression further simplifies to

$$\boldsymbol{\nabla}\cdot\boldsymbol{\nabla}\psi = \partial_r^2\boldsymbol{\psi} + \frac{1}{r}\left(\partial_r + \frac{1}{r}\partial_\theta^2\right)\boldsymbol{\psi} + \frac{1}{r\sin\theta}\left(\sin\theta\partial_r + \cos\theta\frac{1}{r}\partial_\theta + \frac{1}{r\sin\theta}\partial_\phi^2\right)\psi.$$

Collecting the terms we obtain for the Laplace operator

$$\Delta = \partial_r^2 + \frac{2}{r}\partial_r + \frac{1}{r^2}\partial_\theta^2 + \frac{\cos\theta}{r^2\sin\theta}\partial_\theta + \frac{1}{r^2\sin^2\theta}\partial_\phi^2,$$

which can be written in the form (1.15). □

1.1.1.2 Laplacian in cylindrical coordinates

To describe central symmetry in *two-dimensional systems* or systems with *cylindrical symmetry* it is important to be aware of the expression for the laplacian in *cylindrical coordinates* $\mathbf{P} = \mathbf{P}(x, y, z) = \mathbf{P}\,(r_\perp, \phi, z)$. As illustrated in Fig. 1.2 the relation between the cartesian coordinates and the cylindrical coordinates is given by the expressions

$$x = r_\perp\cos\phi,\;\; y = r_\perp\sin\phi,\;\; z = z. \tag{1.16}$$

Using $\partial_a\mathbf{P} = h_a\hat{\mathbf{a}}$, with $a \in \{r_\perp, \phi, z\}$, the angular dependence of the unit vectors is given by

$$\hat{\mathbf{r}}_\perp = +\hat{\mathbf{x}}\cos\phi + \hat{\mathbf{y}}\sin\phi \tag{1.17a}$$

$$\hat{\boldsymbol{\phi}} = -\hat{\mathbf{x}}\sin\phi + \hat{\mathbf{y}}\cos\phi \tag{1.17b}$$

$$\hat{\mathbf{z}} = \hat{\mathbf{z}}. \tag{1.17c}$$

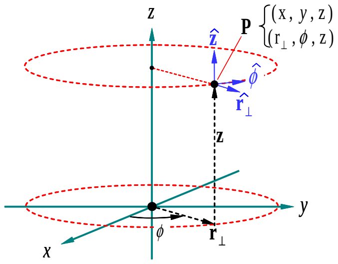

Figure 1.2: Illustration of cylindrical coordinates of a point $\mathbf{P} = \mathbf{P}(x, y, z) = \mathbf{P}\,(r_\perp, \phi, z)$ with unit vector convention.

Using $\mathbf{P} = \hat{\mathbf{r}}_\perp\, r_\perp + \hat{\mathbf{z}}\, z$ we have $\mathbf{P}^2 = r_\perp^2 + z^2$ and calculate $h_{r_\perp} = |\partial\mathbf{P}/\partial r_\perp| = 1$, $h_\phi = |\partial\mathbf{P}/\partial\phi| = r_\perp(\sin^2\phi + \cos^2\phi)^{1/2} = r_\perp$ and $h_z = |\partial\mathbf{P}/\partial z| = 1$.

Hence, in cylindrical coordinates the gradient operator (1.7) is given by

$$\boldsymbol{\nabla} = \hat{\mathbf{r}}_\perp\, \partial_{r_\perp} + \hat{\boldsymbol{\phi}}\frac{1}{r_\perp}\partial_\phi + \hat{\mathbf{z}}\, \partial_z. \tag{1.18}$$

Evaluating the inner product we obtain for the laplacian (see Problem 1.3)

$$\Delta = \frac{\partial^2}{\partial r_\perp^2} + \frac{1}{r_\perp}\frac{\partial}{\partial r_\perp} + \frac{1}{r_\perp^2}\frac{\partial^2}{\partial\phi^2} + \frac{\partial^2}{\partial z^2}. \tag{1.19}$$

Fixing the value of z this expression also serves to describe two-dimensional systems. In the form (1.19) the laplacian is used to describe the flow field of quantized vortices in superfluids.

Problem 1.3. Derive the expression (1.19) for the laplacian in cylindrical coordinates.

Solution. Starting from the vector expression (1.18) for the gradient operator the laplacian is obtained by evaluating the inner product (here we set $r_\perp \!\to \mathbf{r}$ for compactness of notation)

$$\begin{aligned}\boldsymbol{\nabla}\cdot\boldsymbol{\nabla}\psi = \hat{\mathbf{r}}\cdot\left(\partial_r\hat{\mathbf{r}}\,\partial_r + [\partial_r\hat{\boldsymbol{\phi}}]\frac{1}{r}\partial_\phi + [\partial_r\hat{\mathbf{z}}]\partial_z\right)\psi \\ + \frac{1}{r}\hat{\boldsymbol{\phi}}\cdot\left([\partial_\phi\hat{\mathbf{r}}]\partial_r + \partial_\phi\hat{\boldsymbol{\phi}}\frac{1}{r}\partial_\phi + [\partial_\phi\hat{\mathbf{z}}]\partial_z\right)\psi \\ + \hat{\mathbf{z}}\cdot\left([\partial_z\boldsymbol{r}]\,\partial_r + [\partial_z\hat{\boldsymbol{\phi}}]\frac{1}{r}\partial_\phi + \partial_z\hat{\mathbf{z}}\,\partial_z\right)\psi.\end{aligned}$$

Here we dismissed the many terms that yield zero due to the orthogonality of the unit operators. Using $\partial_r\hat{\mathbf{r}} = \partial_r\hat{\boldsymbol{\phi}} = \partial_r\hat{\mathbf{z}} = \partial_z\hat{\mathbf{r}} = \partial_z\hat{\boldsymbol{\phi}} = \partial_z\hat{\mathbf{z}} = 0$ and $\partial_\phi\hat{\mathbf{r}} = \hat{\boldsymbol{\phi}}$, $\partial_\phi\hat{\boldsymbol{\phi}} = -\hat{\mathbf{r}} + \hat{\mathbf{z}}\,z$, $\partial_\phi\hat{\mathbf{z}} = 0$ the expression for $\Delta\psi$ further simplifies to

$$\boldsymbol{\nabla}\cdot\boldsymbol{\nabla}\psi = \partial_r^2\psi + \frac{1}{r}\left(\partial_r + \partial_\phi\frac{1}{r}\partial_\phi\right)\psi + \partial_z^2\psi.$$

Thus, the Laplace operator can be written in the form (1.19). □

1.1.2 Angular momentum operator $\mathbf{L}$

To obtain the operator expression for the angular momentum $\mathbf{L} = \mathbf{r}\times\mathbf{p}$ in the position representation we use the correspondence rules $\mathbf{p} \to -i\hbar\boldsymbol{\nabla}$ and $\mathbf{r} \to \underline{\mathbf{r}}$. Importantly, although $\mathbf{r}$ and $\mathbf{p}$ do not commute the transition to the quantum mechanical expression,

$$\mathbf{L} = -i\hbar\,(\mathbf{r}\times\boldsymbol{\nabla}), \tag{1.20}$$

can be made without ambiguity because the correspondence rules yield the same result for $\mathbf{L} = \mathbf{r} \times \mathbf{p}$ and for $\mathbf{L} = -\mathbf{p} \times \mathbf{r}$. This is easily verified by using the cartesian vector components of $\mathbf{r}$ and $\mathbf{p}$ and their commutation relations,

$$-\left(\mathbf{p} \times \mathbf{r}\right)_i = -\varepsilon_{ijk} p_j r_k = -\varepsilon_{ijk} r_k p_j = \varepsilon_{ikj} r_k p_j = \varepsilon_{ijk} r_j p_k = \left(\mathbf{r} \times \mathbf{p}\right)_i . \tag{1.21}$$

Note that for $j \neq k$ the operators r_j and p_k commute and for $j = k$ one has $\varepsilon_{ijk} = 0$.

Having identified Eq. (1.20) as the proper operator expression for the orbital angular momentum we can turn to arbitrary *orthogonal* curvilinear coordinates $\mathbf{r} = \mathbf{r}(u, v, w)$. In this case the gradient vector is given by $\boldsymbol{\nabla} = \{h_u^{-1}\partial_u, h_v^{-1}\partial_v, h_w^{-1}\partial_w\}$ and the angular momentum operator can be decomposed in the following form

$$\mathbf{L} = -\,i\hbar\,(\mathbf{r} \times \boldsymbol{\nabla}) = -\,i\hbar \begin{vmatrix} \hat{\mathbf{u}} & \hat{\mathbf{v}} & \hat{\mathbf{w}} \\ r_u & r_v & r_w \\ h_u^{-1}\partial_u & h_v^{-1}\partial_v & h_w^{-1}\partial_w \end{vmatrix} . \tag{1.22}$$

For *spherical coordinates* the components of the radius vector are $r_r = r$ and $r_\theta = r_\phi = 0$. Working out the determinant in Eq. (1.22), while *respecting the order* of the vector components r_u and $h_u^{-1}\partial_u$, we find for the angular momentum operator in spherical coordinates

$$\mathbf{L} = -i\hbar\,(\mathbf{r} \times \boldsymbol{\nabla}) = i\hbar \left(\hat{\boldsymbol{\theta}} \frac{1}{\sin\theta} \frac{\partial}{\partial\phi} - \hat{\boldsymbol{\phi}} \frac{\partial}{\partial\theta} \right) . \tag{1.23}$$

Importantly, as was to be expected for a rotation operator in a spherical coordinate system, $\mathbf{L}$ depends only on the angles θ and ϕ and not on the radial distance r.

1.1.3 The operator L_z

The operator for the angular momentum along the z direction is a differential operator obtained by taking the inner product of $\mathbf{L}$ with the unit vector along the z direction, $L_z = \hat{\mathbf{z}} \cdot \mathbf{L}$. From Eq. (1.23) we see that

$$L_z = i\hbar \left((\hat{\mathbf{z}} \cdot \hat{\boldsymbol{\theta}}) \frac{1}{\sin\theta} \frac{\partial}{\partial\phi} - (\hat{\mathbf{z}} \cdot \hat{\boldsymbol{\phi}}) \frac{\partial}{\partial\theta} \right) . \tag{1.24}$$

Because the unit vector $\hat{\boldsymbol{\phi}} = -\hat{\mathbf{x}}\sin\phi + \hat{\mathbf{y}}\cos\phi$ has no z component, only the θ component of $\mathbf{L}$ will give a contribution to L_z. Substituting the unit vector decomposition $\hat{\boldsymbol{\theta}} = \hat{\mathbf{x}}\cos\theta\cos\phi + \hat{\mathbf{y}}\cos\theta\sin\phi - \hat{\mathbf{z}}\sin\theta$ we obtain

$$L_z = -i\hbar \frac{\partial}{\partial\phi}. \tag{1.25}$$

The eigenvalues and eigenfunctions of L_z are obtained by solving the equation

$$-\,i\hbar \frac{\partial}{\partial\phi} \Phi_m(\phi) = m\hbar\; \Phi_m(\phi). \tag{1.26}$$

Here, the eigenvalue m is called the *magnetic quantum number* for the projection of the angular momentum $\mathbf{L}$ on the z axis.[1] The eigenfunctions are

$$\Phi_m(\phi) = a_m e^{im\phi}. \tag{1.27}$$

Assuming the solutions of the Schrödinger equation to be single-valued functions of position,[2] the wavefunction has to be invariant under rotation over 2π about the z axis; i.e., we have to

---

[1] In this chapter we use the shorthand notation m for the magnetic quantum numbers m_l corresponding to states with orbital quantum number l. When other forms of angular momentum appear we will use the subscript notation to discriminate between the different magnetic quantum numbers; e.g., lm_l, sm_s, jm_j, etc..

[2] For a discussion of the single-valuedness see [73, 48]

impose the boundary condition $e^{im\phi} = e^{im(\phi+2\pi)}$. Thus we require $e^{im2\pi} = 1$, which implies $m \in \{0, \pm1, \pm2, \ldots\}$. In other words we quantized the rotation about the z axis. As the orientation of the coordinate system was not defined up to this point, the chosen z direction is called the *quantization axis.* With the normalization

$$\int_0^{2\pi} |\Phi_m(\phi)|^2 \, d\phi = 1 \tag{1.28}$$

we find the same normalization coefficient for all values of the m quantum number, $a_m = (2\pi)^{-1/2}$.

1.1.4 Commutation relations for L_x, L_y, L_z and $\mathbf{L}^2$

The three cartesian components of the angular momentum operator are differential operators satisfying the following commutation relations

$$[L_i, L_j] = i\hbar\varepsilon_{ijk}L_k \quad \Leftrightarrow \quad [L_x, L_y] = i\hbar L_z,\ [L_y, L_z] = i\hbar L_x \text{ and } [L_z, L_x] = i\hbar L_y. \tag{1.29}$$

These expressions are readily derived with the help of some elementary commutator algebra (see Appendix L.8). We derive the relation $[L_x, L_y] = i\hbar L_z$ explicitly; the other commutators are obtained by cyclic permutation of x, y and z. Starting from the definition $L_i = \varepsilon_{ijk} r_j p_k$ we use subsequently the distributive rule (L.29b), the multiplicative rule (L.29d) and the commutation relation (1.9),

$$\begin{aligned} [L_x, L_y] &= [yp_z - zp_y, zp_x - xp_z] = [yp_z, zp_x] + [zp_y, xp_z] \\ &= y\,[p_z, z]\,p_x - x\,[p_z, z]\,p_y = i\hbar(xp_y - yp_x) = i\hbar L_z. \end{aligned} \tag{1.30}$$

A scalar operator always commutes with itself. This well-known commutation rule does *not* hold for vector operators. Two vector operators $\mathbf{A}$ and $\mathbf{B}$ only commute if *all components* of $\mathbf{A}$ commute with all components of $\mathbf{B}$.[1] Hence, $\mathbf{L}$ does *not* commute with itself (see Problem 1.4).

The components of $\mathbf{L}$ commute with $\mathbf{L}^2$,

$$[L_x, \mathbf{L}^2] = 0,\ [L_y, \mathbf{L}^2] = 0,\ [L_z, \mathbf{L}^2] = 0. \tag{1.31}$$

We verify this explicitly for L_z. Using the relation

$$\mathbf{L}^2 = \mathbf{L}\cdot\mathbf{L} = L_x^2 + L_y^2 + L_z^2 \tag{1.32}$$

we obtain with the aid of the multiplicative rule (L.29c)

$$\begin{aligned} &[L_z, L_z^2] = 0 \\ &[L_z, L_y^2] = [L_z, L_y]L_y + L_y[L_z, L_y] = -i\hbar(L_xL_y + L_yL_x) \\ &[L_z, L_x^2] = [L_z, L_x]L_x + L_x[L_z, L_x] = +i\hbar(L_yL_x + L_xL_y). \end{aligned}$$

By adding these terms we find $[L_z, \mathbf{L}^2] = 0$ as well as $[L_z, L_x^2 + L_y^2] = 0$.

Problem 1.4. Vector *operators* differ from classical vectors. Show that

$$\mathbf{L}\times\mathbf{L} = i\hbar\mathbf{L}, \quad [\mathbf{L}, \mathbf{L}] \neq 0, \quad [\mathbf{L}^2, \mathbf{L}^2] = 0.$$

---

[1] The commutator of two *vectors* is a second order tensor. This becomes evident in the Einstein notation $[\mathbf{A}, \mathbf{B}] \Leftrightarrow [A_i, B_j] = A_iB_j - B_jA_i \Leftrightarrow \mathbf{A}\mathbf{B}^T - (\mathbf{B}\mathbf{A}^T)^T$, where $()^T$ represents matrix transposition.

1.1.5 The operators $L_\pm$

The operators

$$L_\pm = L_x \pm i L_y \tag{1.33}$$

are obtained by taking the inner products of $\mathbf{L}$ with the unit vectors along the x and y direction, $L_\pm = (\hat{\mathbf{x}} \cdot \mathbf{L}) \pm i\,(\hat{\mathbf{y}} \cdot \mathbf{L})$. In spherical coordinates this results in

$$L_\pm = i\hbar \left(\left[(\hat{\mathbf{x}} \cdot \hat{\boldsymbol{\theta}}) \pm i(\hat{\mathbf{y}} \cdot \hat{\boldsymbol{\theta}}) \right] \frac{1}{\sin\theta} \frac{\partial}{\partial\phi} - \left[(\hat{\mathbf{x}} \cdot \hat{\boldsymbol{\phi}}) \pm i(\hat{\mathbf{y}} \cdot \hat{\boldsymbol{\phi}}) \right] \frac{\partial}{\partial\theta} \right), \tag{1.34}$$

as follows directly with Eq. (1.23). Substituting the unit vector decompositions $\hat{\boldsymbol{\phi}} = -\hat{\mathbf{x}} \sin\phi + \hat{\mathbf{y}} \cos\phi$ and $\hat{\boldsymbol{\theta}} = \hat{\mathbf{x}} \cos\theta \cos\phi + \hat{\mathbf{y}} \cos\theta \sin\phi - \hat{\mathbf{z}} \sin\theta$ we obtain

$$L_\pm = \hbar e^{\pm i\phi} \left(i \cot\theta \frac{\partial}{\partial\phi} \pm \frac{\partial}{\partial\theta} \right). \tag{1.35}$$

These operators are known as *shift operators* and more specifically as *raising* (L_+) and *lowering* (L_-) operators because their action is to raise or to lower the angular momentum along the quantization axis by one quantum of angular momentum (see Section 1.1.6).

Several useful relations for $L_\pm$ follow straightforwardly. Using the commutation relations (1.29) we obtain

$$[L_z, L_\pm] = [L_z, L_x] \pm i\,[L_z, L_y] = i\hbar L_y \pm \hbar L_x = \pm\hbar L_\pm. \tag{1.36}$$

Further we have

$$L_+ L_- = L_x^2 + L_y^2 - i\,[L_x, L_y] = L_x^2 + L_y^2 + \hbar L_z = \mathbf{L}^2 - L_z^2 + \hbar L_z \tag{1.37a}$$

$$L_- L_+ = L_x^2 + L_y^2 + i\,[L_x, L_y] = L_x^2 + L_y^2 - \hbar L_z = \mathbf{L}^2 - L_z^2 - \hbar L_z, \tag{1.37b}$$

where we used again one of the commutation relations (1.29). Subtracting these equations we obtain

$$[L_+, L_-] = 2\hbar L_z \tag{1.38}$$

and by adding Eqs. (1.37) we find

$$\mathbf{L}^2 = L_z^2 + \tfrac{1}{2}\left(L_+ L_- + L_- L_+\right). \tag{1.39}$$

1.1.6 The operator $\mathbf{L}^2$

To derive an expression for the operator $\mathbf{L}^2$ we use the operator relation (1.39). Substituting Eqs. (1.25) and (1.35) we obtain after some straightforward manipulation

$$\mathbf{L}^2 = -\hbar^2 \left[\frac{1}{\sin^2\theta} \frac{\partial^2}{\partial\phi^2} + \frac{1}{\sin\theta} \frac{\partial}{\partial\theta} \sin\theta \frac{\partial}{\partial\theta} \right]. \tag{1.40}$$

The eigenfunctions and eigenvalues of $\mathbf{L}^2$ are obtained by solving the equation

$$-\hbar^2 \left[\frac{1}{\sin^2\theta} \frac{\partial^2}{\partial\phi^2} + \frac{1}{\sin\theta} \frac{\partial}{\partial\theta} \sin\theta \frac{\partial}{\partial\theta} \right] Y(\theta, \phi) = \lambda\hbar^2 Y(\theta, \phi). \tag{1.41}$$

Because the operators $\mathbf{L}^2$ and L_z commute they share a complete set of eigenstates (see Problem F.1); i.e., the shared eigenfunctions $Y(\theta, \phi)$ must be of the form $Y(\theta, \phi) = P(\theta, \phi)\Phi_m(\phi)$, where the function $\Phi_m(\phi)$ is an eigenfunction of the L_z operator. Because of Eq. (1.26) this implies that $L_z P(\theta, \phi) \equiv 0$, which can only be satisfied for arbitrary value of θ if the variables θ and ϕ separate:

$P(\theta,\phi) = P(\theta)Q(\phi)$. In turn this requires $L_z Q(\phi) \equiv 0$, which can only be satisfied if $Q(\phi)$ is a constant. Thus, we conclude that the shared eigenfunctions $Y(\theta,\phi)$ must be of the form

$$Y(\theta,\phi) = P(\theta)\Phi_m(\phi). \tag{1.42}$$

Evaluating the second order derivative $\partial^2/\partial\phi^2$ in Eq. (1.41) we obtain

$$\left[\frac{1}{\sin\theta}\frac{\partial}{\partial\theta}\sin\theta\frac{\partial}{\partial\theta} - \frac{m^2}{\sin^2\theta} + \lambda\right] P(\theta) = 0. \tag{1.43}$$

As this equation is real its solutions are real functions of the variable θ. Introducing the notation $\lambda = l(l+1)$ and $u \equiv \cos\theta$ (with θ restricted to the interval $0 \le \theta \le \pi$) this equation takes the form of the associated Legendre differential equation (L.36),

$$\left[\left(1-u^2\right)\frac{d^2}{du^2} - 2u\frac{d}{du} + l(l+1) - \frac{m^2}{1-u^2}\right] P_l^m(u) = 0. \tag{1.44}$$

Since $0 \le \theta \le \pi$ we have $\sin\theta = \sqrt{1-u^2} \ge 0$. The solutions are determined up to a constant factor, which has to be fixed by convention. For $m = 0$ the Eq. (1.44) reduces to the Legendre differential equation and its normalized solutions are the *Legendre polynomials*, defined by

$$P_l(u) = \frac{1}{2^l l!}\frac{d^l}{du^l}(u^2-1)^l. \tag{1.45}$$

The solution $P_l(u)$ is a real polynomial of degree $l \in \{0,1,2\cdots\}$ with l zeros in the interval $-1 \le u \le 1$. The Legendre polynomials of lowest degree are

$$P_0(u) = 1, \quad P_1(u) = u, \quad P_2(u) = \tfrac{1}{2}(3u^2-1). \tag{1.46}$$

Note that the sign of the highest power term is chosen to be positive. For $m \neq 0$ the solutions are the *associated Legendre functions* $P_l^m(u)$, real functions which can be written as the product of a positive function $(1-u^2)^{m/2}$ and a polynomial of degree $(l-m)$, parity $(-1)^{l-m}$ with $(l-m)$ zeros in the interval $-1 \le u \le 1$. For $m = 0$ we define $P_l^0(u) \equiv P_l(u)$. For $m > 0$ the $P_l^m(u)$ are obtained by differentiation of the Legendre polynomials,[1]

$$P_l^m(u) = (-1)^m(1-u^2)^{m/2}\frac{d^m}{du^m}P_l(u). \tag{1.47}$$

The *parity* of the $P_l^m(u)$ is given by

$$P_l^m(-u) = (-1)^{l-m}P_l^m(u) \tag{1.48}$$

and the above definitions fix the normalization,

$$\int_{-1}^{1}\left[P_l^m(u)\right]^2 du = \frac{2}{2l+1}\frac{(l+m)!}{(l-m)!}. \tag{1.49}$$

As Eq. (1.44) depends on m^2 we also can define solutions for $m < 0$. Obviously, $P_l^{-m}(u)$ and $P_l^m(u)$ are in essence the same but for the $P_l^{-m}(u)$ we still have to define sign and normalization. Unfortunately, several competing conventions can be found in the literature. In this course we use a positive sign and adhere to the convention in which the normalization (1.49) is valid for both positive and negative m. This is realized by extending the $P_l^m(u)$ to negative m by the relation

$$P_l^{-m}(u) \equiv (-1)^m\frac{(l-m)!}{(l+m)!}P_l^m(u), \tag{1.50}$$

where $0 \le m \le l$. The inclusion of the phase factor $(-1)^m$ in *both* Eq. (1.47) and (1.50) is referred to as the *Condon and Shortley phase convention* [28]. It implies that the phase factor $(-1)^m$ is present for positive m but absent for negative m. Note that the $P_l^m(u)$ are nonzero only for $-l \le m \le l$; i.e., the index m can assume $2l+1$ possible values for a given value of l.

---

[1] Beware of other phase conventions for the $P_l^m(u)$, they affect the recursion relations.

1.1.6.1 Spherical harmonics - Condon and Shortley phase convention

At this point we define the *spherical harmonics* (cf. Section L.9.1)

$$Y_l^m(\theta,\phi)=A_m P_l^m(\cos\theta)e^{im\phi} \tag{1.51}$$

as the joint eigenfunctions of $\mathbf{L}^2$ and L_z in the position representation,

$$\mathbf{L}^2\, Y_l^m(\theta,\phi)=l(l+1)\hbar^2\, Y_l^m(\theta,\phi) \tag{1.52}$$

$$L_z\, Y_l^m(\theta,\phi)=m\hbar\, Y_l^m(\theta,\phi). \tag{1.53}$$

The prefactor A_m is a normalization constant. Combining the normalization integrals (1.28) and (L.46) we obtain

$$Y_l^m(\theta,\phi)=\sqrt{\frac{2l+1}{4\pi}\frac{(l-m)!}{(l+m)!}}P_l^m(\cos\theta)e^{im\phi}, \tag{1.54}$$

with $-l\le m\le l$. The Condon and Shortley phase convention assures that the shift operators satisfy the following relations

$$\begin{aligned} L_\pm Y_l^m(\theta,\phi) &= \sqrt{(l\mp m)\,(l\pm m+1)}\,\hbar\, Y_l^{m\pm1}(\theta,\phi)\\ &= \sqrt{l\,(l+1)-m(m\pm1)}\,\hbar\, Y_l^{m\pm1}(\theta,\phi), \end{aligned} \tag{1.55}$$

with a *positive sign* in front of the square root for *all* values of l and m. Eqs. (1.55) are readily obtained with the aid of Eqs. (1.35) and the recursion relations (L.49). The *parity* of the $Y_l^m(\theta,\phi)$ under inversion in 3D, $\hat{\mathbf{r}}=(\theta,\phi)\to-\hat{\mathbf{r}}=(\pi-\theta,\phi+\pi)$, is independent of m and given by

$$Y_l^m(-\hat{\mathbf{r}})=(-1)^l Y_l^m(\hat{\mathbf{r}}) \tag{1.56}$$

as follows with Eqs. (1.54) and (1.48); i.e., the parity is even for l even and odd for l odd. This makes *parity* into a property defining *selection rules* in atomic transitions.

1.1.7 Orbital angular momentum in Dirac notation

The observables of the orbital angular momentum are represented by the operators $\mathbf{L}^2$ and L_z. In Dirac notation (cf. Appendix F.1.1) their shared basis is defined by

$$\mathbf{L}^2\,|l,m\rangle=l(l+1)\hbar^2\,|l,m\rangle \tag{1.57a}$$

$$L_z\,|l,m\rangle=m\hbar\,|l,m\rangle\,, \tag{1.57b}$$

where the $|l,m\rangle$ are abstract state vectors in Hilbert space, with l and m the *rotational quantum numbers.* The spherical harmonics

$$Y_l^m(\theta,\phi)\equiv Y_l^m(\hat{\mathbf{r}})=\langle\hat{\mathbf{r}}|l,m\rangle \tag{1.58}$$

are the corresponding wavefunctions in the position representation using spherical coordinates. The action of the shift operators $L_\pm$ is given by

$$L_\pm\,|l,m\rangle=\sqrt{l\,(l+1)-m(m\pm1)}\,\hbar\,|l,m\pm1\rangle\,, \tag{1.59}$$

with a *positive sign* in front of the square root for *all* values of l and m. The latter requirement constitutes the Condon and Shortley phase convention for the eigenstates $|l,m\rangle$ (cf. Section 1.1.6.1).

1.1.8 Radial momentum operator p_r

Thus far we succeeded in quantizing the Schrödinger Hamiltonian $\mathcal{H}_0$ and the angular momentum $\mathbf{L}$. Let us now turn to the radial momentum $p_r = \hat{\mathbf{r}} \cdot \mathbf{p}$. Here we have a difficulty because the correspondence rules are not unambiguous in this case. In classical mechanics the expressions $p_r = \hat{\mathbf{r}} \cdot \mathbf{p}$ and $p_r = \mathbf{p} \cdot \hat{\mathbf{r}}$ are identities but since $\hat{\mathbf{r}} = \mathbf{r}/r$ and $-i\hbar\boldsymbol{\nabla}$ do not commute this is not the case for $p_r = -i\hbar\,(\boldsymbol{\nabla} \cdot \hat{\mathbf{r}})$ and $p_r = -i\hbar\,(\hat{\mathbf{r}} \cdot \boldsymbol{\nabla})$. There is a way around this problem. Since we know how to quantize $\mathbf{p}^2$ and $(\hat{\mathbf{r}} \times \mathbf{p})^2$, we infer with the aid of Eq. (1.4) that the radial momentum must be given by

$$p_r^2 = (\hat{\mathbf{r}} \cdot \mathbf{p})^2 = \mathbf{p}^2 - (\hat{\mathbf{r}} \times \mathbf{p})^2 = -\hbar^2\Delta - \mathbf{L}^2/r^2. \tag{1.60}$$

Substituting Eqs. (1.15) and (1.40) this yields

$$p_r^2\psi = -\hbar^2\left(\frac{\partial^2}{\partial r^2} + \frac{2}{r}\frac{\partial}{\partial r}\right)\psi = -\hbar^2\left(\frac{\partial}{\partial r} + \frac{1}{r}\right)^2\psi = -\hbar^2\frac{1}{r}\frac{\partial^2}{\partial r^2}\left(r\psi\right). \tag{1.61}$$

Hence, up to a sign, the radial momentum in spherical coordinates is given by

$$p_r\psi = -i\hbar\left(\frac{\partial}{\partial r} + \frac{1}{r}\right)\psi = -i\hbar\frac{1}{r}\frac{\partial}{\partial r}(r\psi). \tag{1.62}$$

We shall use the sign convention of Eq. (1.62). This implies the commutation relation

$$[r, p_r] = i\hbar. \tag{1.63}$$

Importantly, since L is independent of r and p_r is independent of θ and ϕ, we find that p_r^2 commutes with both L_z and $\mathbf{L}^2$,

$$\left[p_r^2, L_z\right] = 0 \quad \text{and} \quad \left[p_r^2, \mathbf{L}^2\right] = 0. \tag{1.64}$$

In Problem 1.5 it is shown that p_r is only *hermitian* if one restricts oneself to the sub-class of normalizable wavefunctions which are *regular* in the origin; i.e.,

$$\lim_{r\to 0} r\psi(\mathbf{r}) = 0.$$

This additional condition is essential to select *physically relevant solutions* for the (radial) wavefunction. Here we mean by physically relevant that the wavefunction satisfies not only the laplacian in spherical coordinates (which is not defined in the origin) but also the laplacian in cartesian coordinates (which is defined throughout space).

Problem 1.5. Show that p_r is hermitian for square-integrable functions $\psi(r)$ only if they are regular at the origin, i.e. $\lim_{r\to 0} r\psi(r) = 0$.

Solution. For p_r to be hermitian we require the following expression to be zero for any wavefunction ψ within its Hilbert space:

$$\begin{aligned}
\langle\psi, p_r\psi\rangle - \langle\psi, p_r\psi\rangle^* &= -i\hbar\int\left[\psi^*\frac{1}{r}\frac{\partial}{\partial r}\left(r\psi\right) + \frac{1}{r}\psi\frac{\partial}{\partial r}\left(r\psi^*\right)\right]r^2 dr d\Omega \\
&= -i\hbar\int\left[r\psi^*\frac{\partial}{\partial r}\left(r\psi\right) + r\psi\frac{\partial}{\partial r}\left(r\psi^*\right)\right]dr d\Omega \\
&= -i\hbar\int\frac{\partial}{\partial r}\left|r\psi\right|^2 dr d\Omega.
\end{aligned}$$

For this to be zero we require

$$\int\frac{\partial}{\partial r}\left|r\psi\right|^2 dr = \left[\left|r\psi\right|^2\right]_0^\infty = 0.$$

Because $\psi(r)$ is taken to be a square-integrable function; i.e., $\int\left|r\psi\right|^2 dr = \mathcal{N}$ with $\mathcal{N}$ finite, we have $\lim_{r\to\infty} r\psi(r) = 0$ and $\lim_{r\to 0} r\psi(r) = \chi_0$, where χ_0 is (in general) finite. Thus, for p_r to be hermitian we require $\psi(r)$ to be regular in the origin ($\chi_0 = 0$) on top of being square-integrable. However, square-integrable eigenfunctions of p_r can also be irregular at the origin and have complex eigenvalues, e.g.

$$p_r \frac{\exp[-\alpha r]}{r} = -\frac{i\hbar}{r}\frac{\partial}{\partial r} r \frac{\exp[-\alpha r]}{r} = i\hbar\alpha \frac{\exp[-\alpha r]}{r}. \qquad \square$$

Problem 1.6. Show that the radial momentum operator can be written in the form

$$p_r = \tfrac{1}{2}\left(\hat{\mathbf{r}} \cdot \mathbf{p} + \mathbf{p} \cdot \hat{\mathbf{r}}\right) = -\frac{i\hbar}{2}\left[\frac{\mathbf{r}}{r} \cdot \boldsymbol{\nabla} + \boldsymbol{\nabla} \cdot \left(\frac{\mathbf{r}}{r}\right)\right]. \tag{1.65}$$

Verify that in two dimensions p_r cannot be written in the form given on the r.h.s..

1.2 Schrödinger equation

1.2.1 Schrödinger equation in spherical coordinates

We are now in a position to write down the Schrödinger equation of a (reduced) mass m_r moving at energy E in a *central* potential field $\mathcal{V}(r)$

$$\left[\frac{1}{2m_r}\left(p_r^2 + \frac{\mathbf{L}^2}{r^2}\right) + \mathcal{V}(r)\right] \psi(r,\theta,\phi) = E\psi(r,\theta,\phi). \tag{1.66}$$

Because the operators $\mathbf{L}^2$ and L_z commute with the Hamiltonian[1] they share a complete set of eigenstates with that Hamiltonian (See Problem F.1); i.e., the shared eigenfunctions $\psi(r,\theta,\phi)$ must be of the form $\psi = R(r,\theta,\phi)Y_l^m(\theta,\phi)$, which implies $\mathbf{L}^2 R(r,\theta,\phi) \equiv 0$ in view of Eq. (1.52). This can only be satisfied for arbitrary values of r if the radial variable can be separated from the angular variables, $R(r,\theta,\phi) = R(r)X(\theta,\phi)$. In turn this requires $\mathbf{L}^2 X(\theta,\phi) \equiv 0$, which implies that $X(\theta,\phi)$ must be a constant. Thus, we conclude that the shared eigenfunctions $\psi(r,\theta,\phi)$ must be of the form

$$\psi(r,\theta,\phi) = R_{nl}(r)Y_l^m(\theta,\phi), \tag{1.67}$$

where the quantum number n appears to allow for more than one solution of given l. Hence, using Eq. (1.52) and substituting Eqs. (1.61) and (1.67) into Eq. (1.66) we obtain

$$\left[\frac{\hbar^2}{2m_r}\left(-\frac{\partial^2}{\partial r^2} - \frac{2}{r}\frac{\partial}{\partial r} + \frac{l(l+1)}{r^2}\right) + \mathcal{V}(r)\right] R_{nl}(r)Y_l^m(\theta,\phi) = E R_{nl}(r)Y_l^m(\theta,\phi). \tag{1.68}$$

Here the term

$$\mathcal{V}_{\text{rot}}(r) \equiv \frac{l(l+1)\hbar^2}{2m_r r^2} \tag{1.69}$$

is called the *rotational energy barrier* and represents the *centrifugal energy* at a given distance from the origin and for a given value of the angular momentum. Because the operator on the left of Eq. (1.68) is independent of θ and ϕ we can eliminate the functions $Y_l^m(\theta,\phi)$ from this equation. The remaining equation takes the form of the *radial wave equation*.

$$\left[\frac{\hbar^2}{2m_r}\left(-\frac{d^2}{dr^2} - \frac{2}{r}\frac{d}{dr} + \frac{l(l+1)}{r^2}\right) + \mathcal{V}(r)\right] R_{nl}(r) = E R_{nl}(r), \tag{1.70}$$

where the solutions $R_{nl}(r)$ must depend on r but be independent of θ and ϕ. Note that the solutions do not depend on m because the Hamiltonian does not depend on L_z. This is a property of central potentials.

---

[1] Note that L_z commutes with $\mathbf{L}^2$ (see Section 1.1.6); L_z and $\mathbf{L}^2$ commute with r and p_r (see Section 1.1.8).

Reduction to one-dimensional Schrödinger equation

Eq. (1.70) is the starting point for the description of the relative radial motion of any particle in a central potential field. Introducing the quantities

$$\varepsilon = 2m_r E/\hbar^2 \quad \text{and} \quad U(r) = 2m_r \mathcal{V}(r)/\hbar^2, \tag{1.71}$$

Suppressing the quantum number n, Eq. (1.70) can be written in the compact form

$$R_l'' + \frac{2}{r}R_l' + \left[\varepsilon - U(r) - \frac{l(l+1)}{r^2}\right] R_l = 0, \tag{1.72}$$

where the prime refers to a derivative with respect to r. Eq. (1.61) suggests to introduce so-called *reduced* radial wavefunctions

$$\chi_l(r) = rR_l(r), \tag{1.73}$$

which allows us to reduce the radial wave equation (1.70) to the form of a one-dimensional Schrödinger equation

$$\chi_l'' + \left[\frac{2m_r}{\hbar^2}(E - \mathcal{V}) - \frac{l(l+1)}{r^2}\right]\chi_l = 0. \tag{1.74}$$

The 1D-Schrödinger equation is a second-order differential equation of the following general form

$$\chi'' + F(r)\chi = 0. \tag{1.75}$$

Equations of this type satisfy some general properties. These are related to the Wronskian theorem, which is derived and discussed in appendix L.13.

Not all solutions of the 1D Schrödinger equation are physically acceptable. The physical solutions must be normalizable; i.e., for bound states

$$\int r^2 |R(r)|^2 \, dr = \int |\chi(r)|^2 \, dr = \mathcal{N}, \tag{1.76}$$

where $\mathcal{N}$ is a finite number. However, there is an additional requirement. Because the Hamiltonian (1.3) is only valid outside the origin ($r \neq 0$) the solutions of the radial wave equation are not necessarily valid *at* the origin. To be valid for all values of r the solutions must, in addition to be being normalizable, also be *regular* in the origin; i.e., $\lim_{r\to 0} rR(r) = \lim_{r\to 0}\chi(r) = 0$. Although this is stated without proof we demonstrate in Problem 1.7 that normalizable wavefunctions $\psi(\mathbf{r})$ scaling like $R(r) \sim 1/r$ near the origin do not satisfy the Schrödinger equation in the origin. All this being said, only wavefunctions based on the *regular* solutions of Eqs. (1.70) and (1.74) can be valid solutions for all values of r, *including the origin.*

Problem 1.7. Show that a normalizable radial wavefunction scaling like $R(r) \sim 1/r$ for $r \to 0$ does not satisfy the Schrödinger equation in the origin.

Solution. Next we turn to solutions $\psi(\mathbf{r}) = R_l(r)Y_l^m(\theta,\phi)$ of the Schrödinger equation for the motion of a particle in a central field. We presume that the wavefunction is well behaved everywhere but diverges like $R_l(r) \sim 1/r$ for $r \to 0$. We ask ourselves whether this is a problem because - after all - the wavefunction is normalizable. However, the divergent wavefunction $R_l(r)$ is defined everywhere except in the origin. This is more than a technicality because it implies that the Schrödinger equation is *not* satisfied in the origin. Using Problem 1.9 we find

$$\left(-\frac{\hbar^2}{2m_r}\Delta + \mathcal{V}(r) - E\right)\psi(\mathbf{r}) = -\frac{4\pi\hbar^2}{2m_r}\delta(\mathbf{r}),$$

which is zero everywhere *except in the origin.* Apparently, by solving the Schrödinger equation after separation in radial and angular variables we have generated a solution that does not satisfy the original equation (which is valid everywhere in space - including the origin). □

Problem 1.8. Show that for a normalizable radial wavefunction scaling like $R(r) \sim 1/r$ for $r \to 0$ the kinetic energy diverges in the origin.

Solution. We first write the radial wavefunction in the form $R_0(r) = (\chi_0(r)/r)$, where $\chi_0(r)$ is nonzero in the origin, $\lim_{r\to 0}\chi_0(r) = \chi_0(0) \neq 0$. Calculating the kinetic energy we find

$$\begin{aligned} -\int R_0(r)Y_0^0(\theta,\phi)\,\frac{\hbar^2}{2m_r}\Delta R_0(r)Y_0^0(\theta,\phi)\,d\mathbf{r} &> -\frac{\hbar^2}{2m_r}\chi_0^2(0)\lim_{\epsilon\to 0}\int_V \frac{1}{4\pi r}\Delta\frac{1}{r}d\mathbf{r} \\ &= -\frac{\hbar^2}{2m_r}\chi_0^2(0)\lim_{\epsilon\to 0}\int_V \frac{1}{r}\delta(\mathbf{r})\,d\mathbf{r} \to \infty. \end{aligned}$$ □

Problem 1.9. Use the Gauss theorem to demonstrate the relation $\Delta(1/r) = -4\pi\delta(\mathbf{r})$.

Solution. We first integrate this expression on both sides over a small sphere V of radius ϵ centered at the origin,

$$\int_V \Delta\frac{1}{r}d\mathbf{r} = -4\pi.$$

Here we used $\int_V \delta(\mathbf{r})\,d\mathbf{r} = 1$ for an arbitrarily small sphere at the origin. The l.h.s. also yields -4π as follows with the divergence theorem (Gauss theorem)

$$\lim_{\epsilon\to 0}\int_V \Delta\frac{1}{r}d\mathbf{r} = \lim_{\epsilon\to 0}\oint_S d\mathbf{S}\cdot\boldsymbol{\nabla}\frac{1}{r} = \lim_{\epsilon\to 0}\oint_S d\mathbf{S}\cdot\hat{\mathbf{r}}\left(-\frac{1}{r^2}\right) = \lim_{\epsilon\to 0}4\pi\epsilon^2\left(-\frac{1}{\epsilon^2}\right) = -4\pi.$$ □

1.2.2 Schrödinger equation in cylindrical coordinates

In systems with cylindrical symmetry about the z axis (see Fig. 1.2) the motion separates into motion parallel to the z axis and motion in planes orthogonal to the z axis,

$$\mathbf{p}^2 = (\hat{\mathbf{z}}\cdot\mathbf{p})^2 + (\hat{\mathbf{r}}_\perp\cdot\mathbf{p}_\perp)^2 + (\hat{\mathbf{r}}_\perp\times\mathbf{p}_\perp)^2, \tag{1.77}$$

where $\hat{\mathbf{r}}_\perp$ is defined in Eq. (1.17a) and $\hat{\mathbf{z}}$ is independent of position; $\mathbf{p}_\perp$ is the momentum in the xy plane. The quantization rule for the linear momentum in the z direction, $p_z\phi = \hat{\mathbf{z}}\cdot\mathbf{p}\phi \to -i\hbar\hat{\mathbf{z}}\cdot\boldsymbol{\nabla}\phi = -i\hbar\partial_z\phi$, can be applied without ambiguity and we have for the p_z^2 operator

$$p_z^2 = (\hat{\mathbf{z}}\cdot\mathbf{p})^2 = -\hbar^2\partial^2/\partial z^2. \tag{1.78}$$

With regard to the motion in planes orthogonal to the z axis we run into the same dilemma as we encountered with spherical coordinates. The quantization rules for $\hat{\mathbf{r}}_\perp\cdot\mathbf{p}_\perp = \mathbf{p}_\perp\cdot\hat{\mathbf{r}}_\perp$ are not unambiguous since $\hat{\mathbf{r}}_\perp\cdot\boldsymbol{\nabla}_\perp\phi \neq \boldsymbol{\nabla}_\perp\cdot\hat{\mathbf{r}}_\perp\phi$ (the direction of the unit vector $\hat{\mathbf{r}}_\perp$ depends on position). This dilemma can be circumvented in the same way as we did for p_r in Section 1.1.8. By rewriting Eq. (1.77) in the form

$$p_{r_\perp}^2 = (\hat{\mathbf{r}}_\perp\cdot\mathbf{p}_\perp)^2 = \mathbf{p}^2 - (\hat{\mathbf{r}}_\perp\times\mathbf{p}_\perp)^2 - (\hat{\mathbf{z}}\cdot\mathbf{p})^2 \tag{1.79}$$

we obtain an expression where $p_{r_\perp}$ is expressed in quantities for which the correspondence rules can be applied without ambiguity: $\mathbf{p}^2 \to -\hbar^2\Delta$ and $\hat{\mathbf{r}}_\perp\times\mathbf{p}_\perp \to -i\hbar\hat{\mathbf{r}}_\perp\times\boldsymbol{\nabla}_\perp$. Note that for cylindrical coordinates the angular momentum along the symmetry axis, $\mathbf{L}_\perp = \mathbf{r}_\perp\times\mathbf{p}_\perp$, satisfies the property

$$\mathbf{L}_\perp = -i\hbar\frac{\partial}{\partial\phi} = L_z. \tag{1.80}$$

Replacing the dynamical variables by their operators Eq. (1.79) takes the form

$$p_{r_\perp}^2 = -\hbar^2\left(\Delta - \frac{1}{r_\perp^2}\frac{\partial^2}{\partial\phi^2} - \frac{\partial^2}{\partial z^2}\right). \tag{1.81}$$

Substituting Eq. (1.19) for the laplacian we obtain

$$p_{r_\perp}^2 = -\hbar^2\left(\frac{\partial^2}{\partial r_\perp^2} + \frac{1}{r_\perp}\frac{\partial}{\partial r_\perp}\right). \tag{1.82}$$

At this point we can quantize the Hamiltonian and starting from Eq. (1.77) the Schrödinger equation takes the form

$$\left[-\frac{\hbar^2}{2m_r}\left(\frac{\partial^2}{\partial r_\perp^2}+\frac{1}{r_\perp}\frac{\partial}{\partial r_\perp}+\frac{\partial^2}{\partial z^2}\right)+\frac{L_z^2}{2m_r r_\perp^2}+\mathcal{V}(r_\perp,\phi,z)\right]\psi(r_\perp,\phi,z)=E\psi(r_\perp,\phi,z). \tag{1.83}$$

If the potential only depends on the $r_\perp$ variable, $\mathcal{V}(r_\perp,\phi,z)=\mathcal{V}(r_\perp)$, we have separation of variables for the axial, radial and angular motion and we find for the radial Schrödinger equation in this case

$$\frac{\hbar^2}{2m_r}\left(-\frac{d^2}{dr_\perp^2}-\frac{1}{r_\perp}\frac{d}{dr_\perp}+\frac{l^2}{r_\perp^2}+\mathcal{V}(r_\perp)\right)R_{nl}(r_\perp)=ER_{nl}(r_\perp). \tag{1.84}$$

Reduction to one-dimensional Schrödinger equation

Suppressing the quantum number n and using the definitions (1.71) the radial wave equation (1.84) takes the compact form

$$R_l''+\frac{1}{r_\perp}R_l'+\left[\varepsilon-U(r_\perp)-\frac{m^2}{r_\perp^2}\right]R_l=0, \tag{1.85}$$

where the prime refers to a derivative with respect to $r_\perp$. Introducing the functions

$$y_l(r_\perp)=r_\perp^{1/2}R_l(r_\perp), \tag{1.86}$$

also in this case the radial wave equation is reduced to the form of a one-dimensional Schrödinger equation,

$$y_l''+\left[\frac{2m_r}{\hbar^2}\left(E-\mathcal{V}\right)+\frac{1/4-m^2}{r_\perp^2}\right]y_l=0. \tag{1.87}$$

1.3 Symmetry properties, conserved quantities and good quantum numbers

To conclude this chapter we return to the Schrödinger Hamiltonian,

$$\mathcal{H}_0=-\frac{\hbar^2}{2m_r}\Delta+\mathcal{V}(r), \tag{1.88}$$

and discuss the main findings of the chapter against the background of the symmetry properties of this Hamiltonian. In general, the symmetries of a physical quantity are defined by the set of coordinate transformations that leave this quantity invariant. With each symmetry we associate an operator that generates the corresponding coordinate transformation. The transformations may be continuous (e.g., translation and rotation) or discrete (e.g., reflection and inversion). For instance, an equilateral triangle is invariant under rotation over 120° about an axis through the center of mass and perpendicular to the plane of the triangle; this reveals a three-fold symmetry under rotation (a finite rotation symmetry in this case). The mathematical discipline for the investigation of symmetry properties is called *Group theory* [111].

What are the symmetries of the Schrödinger Hamiltonian? For the potential energy term this is self evident from the notation because the central potential $\mathcal{V}(r)$ depends only on the radial distance $r=|\mathbf{r}|$ to the atomic center of mass. This manifestly being the case, $\mathcal{V}(r)$ is said to be *manifestly invariant* under any transformation that does not affect $|\mathbf{r}|$. This is the case for all *rotations* about the origin, all *reflections* about a plane through the origin and for *inversion* about the origin. For the kinetic energy term the symmetry under such operations is certainly not manifest and we need to have a closer look.

As an example we consider the *space inversion* by the *parity operator* P. This operator transforms the position $\mathbf{r}$ into position $-\mathbf{r}$, which is equivalent to sign reversal of the cartesian coordinates ($x\to -x$, $y\to -y$, $z\to -z$). As this operation conserves $|\mathbf{r}|$, the potential energy is invariant under space inversion. To determine the inversion symmetry of the kinetic energy operator we write the laplacian in cartesian coordinates,

$$\Delta = \frac{\partial^2}{\partial x^2} + \frac{\partial^2}{\partial y^2} + \frac{\partial^2}{\partial z^2}. \tag{1.89}$$

As this expression only contains second derivatives with regard to position it also is invariant under sign reversal. In other words the *Schrödinger Hamiltonian conserves parity for any interaction that conserves parity.* Note that by inverting twice we obtain the unit operator, $P^2 = \mathbb{1}$. In group theory P and P^2 are said to be the elements of a group of order 2: the inversion group (P^2 is the identity element). In the language of quantum mechanics we say that P commutes with the Hamiltonian. This implies that P is a hermitian operator; hence, its eigenvalues are real. As $P^2 = \mathbb{1}$ these eigenvalues are 1 (*even parity*) or -1 (*odd parity*). The radius vector is odd under parity (such vectors are called *polar vectors*). Angular momentum is even under parity (such vectors are called *axial vectors* or *pseudo vectors*). As P commutes with $\mathcal{H}_0$, also the energy eigenstates must be parity eigenstates. This property was already noticed in Section 1.1.6.

What about rotational symmetry? From the commutation of L_z with $\mathcal{H}_0$ we find by using the product rule for differentiation

$$\left(\frac{\partial}{\partial\phi}\mathcal{H}_0 - \mathcal{H}_0\frac{\partial}{\partial\phi}\right)\psi(r,\theta,\phi) = \left(\frac{\partial\mathcal{H}_0}{\partial\phi}\right)_\psi \psi(r,\theta,\phi) = 0. \tag{1.90}$$

Because this relation is valid for any function $\psi(r,\theta,\phi)$ it implies the *invariance* of $\mathcal{H}_0$ under an *infinitesimal* rotation about the z axis,

$$\frac{\partial\mathcal{H}_0}{\partial\phi} = 0. \tag{1.91}$$

As the quantization axis was chosen in an arbitrary direction, this invariance of $\mathcal{H}_0$ holds for *any* infinitesimal rotation about the origin. Inversely, it is this invariance that makes L_z commute with $\mathcal{H}_0$, which implies that L_z is a conserved quantity (see Appendix F.2.4). The operator L_z can be identified with the operator for an infinitesimal rotation about the z axis as introduced above. The Hamiltonian is also invariant under any *finite* rotation about the origin because any such rotation can be realized by an infinite sequence of infinitesimal rotations about the origin. The infinite set of all rotations about the origin constitutes the elements of a continuous group: the *full rotation group.*

In this course we raise awareness for the symmetry properties but do not enter into the systematics of group theory. With regard to rotation we emphasize that for the Hamiltonian $\mathcal{H}_0$ the expectation values of $\mathbf{L}^2$ and L_z are *conserved* whatever the radial motion, showing that $\mathbf{L}^2$ and L_z are *observables* (observable constants of the motion). This means that the corresponding eigenvalues and eigenstates can be measured simultaneously to arbitrary precision and are uniquely determined by the quantum numbers l and m_l. Whenever a quantum number is conserved, it is called a *good quantum number* of the Hamiltonian under consideration. As a counter example we consider p_r^2. As p_r^2 does not commute with r (see Section 1.1.8), it does not commute with the Hamiltonian. This means that p_r^2 is not a conserved quantity and no good quantum number can be identified with the radial kinetic energy. This is no surprise from the physical point of view because the radial motion is oscillatory.

2

Hydrogenic atoms

The notion *hydrogenic* refers for atomic systems in which exactly one elementary charge is orbiting the nucleus [14]. Aside from the hydrogen isotopes *hydrogen* (H), *deuterium* (D) and *tritium* (T), ions like singly ionized *helium* (He^+), doubly ionized *lithium* (Li^{2+}) and exotic atoms like *positronium* and *muonic hydrogen* belong to this class. *Hydrogen-like* behavior is more common. It occurs in *one-electron atoms.* This is the class of atoms in which a single electron dominates the atomic properties. This class includes of course the *hydrogenic atoms* but more typically involves *many-electron* atoms with one distinct outer electron, the *valence electron.* Many-electron atoms behave at best *hydrogen-like* because the nuclear charge is partially *screened* by one or more shells of *core electrons.* For instance, hydrogen-like behavior is observed in one-electron *Rydberg atoms.* These are atoms in which the valence electron is excited to a weakly bound state. Other examples are the *alkali-like* atoms. Aside from the alkali (group I) atoms *lithium* (Li), *sodium* (Na), *potassium* (K), *rubidium* (Rb) and *cesium* (Cs) also the singly charged ions of "two-electron" atoms (group II) such as the ions of *magnesium* (Mg^+), *calcium* (Ca^+), *strontium* (Sr^+) and *barium* (Ba^+) are alkali-like.

In the present chapter we focus on the *non-relativistic* theory of hydrogenic atoms. We analyze the electronic motion under influence of the Coulomb interaction with a point-like nucleus; i.e., for the so-called *Bohr atom.* We obtain the *principal structure* of the atom. The typical energy level separation turns out to be a factor α^2 smaller than the electron *rest mass energy,* which justifies the non-relativistic Ansatz ($\alpha \simeq 1/137$ is the *fine-structure constant*).

The subsequent task will be to include *relativistic* corrections. This is the subject of Chapter 4. Relativistic effects give rise to the atomic *fine structure* and manifest themselves most prominently as *magnetic forces.* As these forces are much weaker than Coulomb forces they may be neglected in describing the principal structure. Importantly, being weak does not mean unimportant. Magnetism is crucial for the understanding of many physical phenomena and of seminal importance for major technological applications. As we show in Chapter 4 the weakness of the magnetic interaction is convenient from the theoretical point of view because it allows an analytic description of many magnetic properties with the aid of perturbation theory. As magnetism is intimately related to angular momentum, the properties of angular momentum in its quantum mechanical context are summarized in Chapter 3. Before turning to Chapter 4, also a refreshment of the operational skills on perturbation theory (Appendix H) may prove well invested.

2.1 Hydrogenic atoms

Hydrogenic atoms consist of a single electronic charge orbiting a positively charged nucleus. It was demonstrated by Ernest Rutherford in 1911 that the nucleus is orders of magnitude smaller than the size of the atom [95]. After this discovery the atom was visualized as a miniature planetary system in which the nucleus could be approximated by a point charge. The conceptual step to the modern atom was made by Niels Bohr in 1913 [17, 18, 19]. By quantization of the planetary motion

Bohr formulated the famous Bohr model for the atom which explains the optical spectrum of atomic hydrogen and defines the *principal structure* of the atom. In this section we solve the Bohr atom with the method developed by Erwin Schrödinger in 1926 [99]. To start the discussion we note that the Coulomb interaction between electron and nucleus gives rise to a *central* potential. Hence, the hamiltonian operator to calculate the energy eigenvalues in the absence of externally applied fields is of the general form (1.6) and will be referred to as the *Schrödinger* Hamiltonian for the atom,

$$\mathcal{H}_0 = \frac{\mathbf{p}^2}{2m_r} + \mathcal{V}(r) = -\frac{\hbar^2}{2m_r}\Delta - \frac{Ze^2}{4\pi\varepsilon_0 r}. \tag{2.1}$$

Here r is the electron-nuclear radial distance and m_r the *reduced mass,*

$$m_r = m_e/(1 + m_e/M), \tag{2.2}$$

with $m_e \simeq 9.1 \times 10^{-31}$ Kg the electronic and M the nuclear rest mass. The quantity

$$\mathcal{V}(r) = -e\varphi(r) = -\frac{Ze^2}{4\pi\varepsilon_0 r} \tag{2.3}$$

is the *electrostatic energy*; i.e., the *potential energy* of the *electronic charge*, $-e$, in the electromagnetic *scalar potential* (Coulomb potential) of the nucleus

$$\varphi(r) = \frac{Ze}{4\pi\varepsilon_0 r}, \tag{2.4}$$

where Ze is the nuclear charge, with e being the elementary charge and Z the number of protons in the nucleus; Z is called the *atomic number* or *nuclear charge number.* Furthermore, $\varepsilon_0 = 1/\mu_0 c^2$ is the *vacuum permittivity,*[1] $\mu_0 = 4\pi\alpha\hbar/e^2 c$ the *vacuum permeability* and $c = 299\,792\,458\ \mathrm{m\,s^{-1}}$ the defined value of the *speed of light in vacuum.* The reduced mass has typically a value close to the mass of the free electron but can be substantially smaller for exotic atoms like positronium.

As $\mathcal{V}(r)$ represents a *central* potential energy field, the motion of the electron can be described by a Schrödinger equation of the type (1.66)

$$\left[\frac{1}{2m_r}\left(p_r^2 + \frac{\mathbf{L}^2}{r^2}\right) + \mathcal{V}(r)\right]\psi(r,\theta,\phi) = E\psi(r,\theta,\phi), \tag{2.5}$$

where p_r is the radial momentum operator, $\mathbf{L}$ the angular momentum operator and E the total energy of the system (see Section 1.1). The Hamiltonian commutes simultaneously with $\mathbf{L}^2$ and L_z. Therefore, these operators share a complete set of eigenfunctions with the full Hamiltonian and, as discussed in Section 1.1, can be written in the form of a product of the type

$$\psi_{nlm}(r,\theta,\phi) = R_{nl}(r)Y_l^m(\theta,\phi), \tag{2.6}$$

where n is the *principal quantum number* for the radial motion to be determined later in this chapter. The wavefunctions (2.6) are called *atomic orbitals.* Substituting this expression in Eq. (2.5) we obtain the *radial wave equation*

$$\left[\frac{\hbar^2}{2m_r}\left(-\frac{d^2}{dr^2} - \frac{2}{r}\frac{d}{dr} + \frac{l(l+1)}{r^2}\right) + \mathcal{V}(r)\right]R_{nl}(r) = ER_{nl}(r). \tag{2.7}$$

The term $l(l+1)/r^2$ represents the centrifugal energy in electronic motion (see Section 1.1) and $R_{nl}(r)$ is called the radial wave function. There is a standard convention to refer to the value of the orbital quantum number l

$$\begin{array}{cccccccccccccccccc} l = & 0 & 1 & 2 & 3 & 4 & 5 & 6 & 7 & 8 & 9 & 10 & 11 & 12 & 13 & 14 & 15 & \cdots \\ & s & p & d & f & g & h & i & k & l & m & n & o & q & r & t & u & \cdots \end{array} \tag{2.8}$$

---

[1] Since the redefinition of the SI in 2019, the *vacuum permeability* and *vacuum permittivity* are no longer constants but depend on a measured quantity, the fine-structure constant α. This made the names *magnetic constant* and *electric constant* obsolete.

Table 2.1: Comparison of Hartree (27.2 eV) and Rydberg (13.6 eV) atomic units.

	SI	Hartree†	Rydberg
length unit:	m	$a = \dfrac{4\pi\varepsilon_0\hbar^2}{m_r e^2}$	$a = \dfrac{4\pi\varepsilon_0\hbar^2}{m_r e^2}$
energy unit:	J	$E_H = \dfrac{\hbar^2}{m_r a^2} = 2hcR_M$	$E_R = \dfrac{\hbar^2}{2m_r a^2} = hcR_M$
length:	r	$\rho = r/a$	$\rho = r/a$
energy:	E	$\varepsilon = E/E_H$	$\varepsilon = E/Ry$
$\mathcal{V}(r)$:	$-\dfrac{Ze^2}{4\pi\varepsilon_0 r}$	$U(\rho) = -\dfrac{Z}{\rho}$	$U(\rho) = -2\dfrac{Z}{\rho}$
$\mathcal{V}_{\text{rot}}(r)$	$\dfrac{\hbar^2}{2m_r}\dfrac{l(l+1)}{r^2}$	$U_{\text{rot}}(\rho) = \dfrac{l(l+1)}{2\rho^2}$	$U_{\text{rot}}(\rho) = \dfrac{l(l+1)}{\rho^2}$
$\mathcal{H}_{\text{rad}}(r)$	$-\dfrac{\hbar^2}{2m_r}\left(\dfrac{d^2}{dr^2} + \dfrac{2}{r}\dfrac{d}{dr}\right)$	$\mathcal{H}_{\text{rad}}(\rho) = -\dfrac{1}{2\rho}\dfrac{d^2}{d\rho^2}\rho$	$\mathcal{H}_{\text{rad}}(\rho) = -\dfrac{1}{\rho}\dfrac{d^2}{d\rho^2}\rho$

†Hartree a.u. correspond to setting $m_r = e = \hbar = 1/4\pi\varepsilon_0 = 1$; this implies $a = E_H = 1$.

In this convention one refers to s orbitals ($l = 0$), p orbitals ($l = 1$), d orbitals ($l = 2$), *etc.*. This nomenclature has its origin in atomic spectroscopy, with the first four orbital labels referring to the terms sharp, principal, diffuse, and fundamental. When it adds to the readability of equations one sometimes writes $R_{ns}(r), R_{np}(r), R_{nd}(r), \cdots$, rather than $R_{n0}(r), R_{n1}(r), R_{n2}(r), \cdots$.

2.1.1 Atomic units

The 1D Schrödinger equation is made dimensionless by turning to atomic units (a.u.). For this purpose Eq. (1.74) is multiplied by a^2, where a is a characteristic length to be determined. If we choose a such that

$$\frac{m_r a^2}{\hbar^2}\mathcal{V}(r) = -\frac{m_r a}{\hbar^2}\frac{Ze^2 a}{4\pi\varepsilon_0 r} = -\frac{Z}{\rho} \equiv U(\rho), \tag{2.9}$$

where $\rho = r/a$ is the dimensionless radius, we find that

$$a = \frac{4\pi\varepsilon_0\hbar^2}{m_r e^2} = (m_e/m_r)a_0 = (1 + m_e/M)a_0. \tag{2.10}$$

where $a_0 = 4\pi\varepsilon_0\hbar^2/m_e e^2\,(= \alpha/4\pi R_\infty) \simeq 5.2 \times 10^{-11}$ m is the *Bohr radius.* Note that the proton charge radius, $r_p \simeq 8.8 \times 10^{-16}$ m, is almost 5 orders of magnitude smaller. The characteristic length a obtained with this procedure is called the *atomic unit of length.* The corresponding *Hartree atomic unit of energy* is defined as

$$E_H = \frac{\hbar^2}{m_r a^2} = \frac{1}{4\pi\varepsilon_0}\frac{e^2}{a} = \alpha^2 m_r c^2 = 2hcR_M = \frac{2hcR_\infty}{1 + m_e/M}, \tag{2.11}$$

with $\alpha = e^2/4\pi\varepsilon_0\hbar c = \hbar/m_e c a_0 \simeq 1/137$ being the *fine-structure constant*, and $R_M = R_\infty/(1 + m_e/M)$ and $R_\infty = \alpha^2 m_e c/2h$ the finite-mass/infinite-mass *Rydberg constants*, respectively. Note that $4\pi\alpha^2 a = \mu_0 e^2/m_r$. The *Hartree energy* is defined as $E_h = \alpha^2 m_e c^2 \simeq 4.36 \times 10^{-18}$ J $\simeq 27.2$ eV.[1]

---

[1] Note the difference between the Hartree a.u., $E_H = \hbar^2/m_r a^2 = E_h/(1 + m_e/M)$, and the Hartree energy, E_h.

This shows that the characteristic energy scale of the atom is α^2 times smaller the rest mass energy of the electron. In other words, relativistic phenomena play a minor role in the description of the orbital motion of the electron. Sometimes the *Rydberg atomic unit* is used,[1] 1Ry $\simeq$ 13.6 eV, twice as small as the Hartree and corresponding to the ionization energy of the hydrogen ground state. Hartree and Rydberg atomic units are compared in Table 2.1. The operator for the dimensionless radial kinetic energy $\mathcal{H}_{\mathrm{rad}}(r)$ is given by

$$\frac{m_r a^2}{\hbar^2}\mathcal{H}_{\mathrm{rad}}(r) = \frac{m_r a^2}{\hbar^2}\frac{\hbar^2}{2m_r}\left(-\frac{d^2}{dr^2} - \frac{2}{r}\frac{d}{dr}\right) = -\frac{1}{2\rho}\frac{d^2}{d\rho^2}\rho. \tag{2.12}$$

Defining the energy of bound states as negative, $\varepsilon = -\kappa^2$ (with $\kappa > 0$), we find for the energy in the dimensionless form

$$\varepsilon = -\kappa^2 = \frac{m_r a^2}{\hbar^2}E. \tag{2.13}$$

Hence, in Hartree atomic units the radial wave equation can be written compactly as

$$\tilde{R}_l''/2 + \tilde{R}_l'/\rho + [Z/\rho - l(l+1)/2\rho^2 - \kappa^2]\tilde{R}_l = 0, \tag{2.14}$$

where we suppressed (for the time being) the quantum number n and write

$$\tilde{R}_l(\rho) = \tilde{R}_l(r/a) \equiv a^{3/2}R_l(r) = a^{3/2}R_l(\rho a) \tag{2.15}$$

for the radial wavefunctions redefined as unit-normalized dimensionless functions of ρ,

$$\int R_l^2(r)r^2dr = \int \tilde{R}_l^2(\rho)\rho^2 d\rho = 1. \tag{2.16}$$

The primes in Eq. (2.14) represent derivatives with respect to the variable ρ. Note that in Hartree atomic units ($a \to 1$, $\rho = r/a \to r$) the expressions for $R_l(r)$ and $\tilde{R}_l(\rho)$ coincide. A similar equation can be based on the Rydberg atomic unit of energy, 1Ry $= hcR_M$.

Problem 2.1. Show that in Hartree atomic units $a = 1$, $E_H = 1$, $c = 1/\alpha$, $R_M = \alpha/4\pi$.

2.1.2 Solving the radial wave equation

In this section we solve the radial wave equation (2.14) in dimensionless form using Hartree atomic units. Recalling the substitution

$$\tilde{\chi}_l(\rho) = \rho\tilde{R}_l(\rho), \tag{2.17}$$

we first reformulate Eq. (2.14) into the form of a 1D Schrödinger equation,

$$\tilde{\chi}_l'' + 2\left[Z/\rho - l(l+1)/2\rho^2 - \kappa_l^2\right]\tilde{\chi}_l = 0. \tag{2.18}$$

For $\rho \to 0$ the rotational term is dominant and the 1D equation may be approximated by

$$\tilde{\chi}_l'' + \left[-l(l+1)/\rho^2\right]\tilde{\chi}_l = 0, \tag{2.19}$$

with solutions $\tilde{\chi}_l(\rho) \sim \rho^{l+1}$, regular in the origin for all values of l. Likewise, for $\rho \to \infty$ we may neglect the Z/ρ and $l(l+1)/\rho^2$ terms and obtain (for all values of l)

$$\tilde{\chi}_l'' - 2\kappa_l^2\tilde{\chi}_l = 0, \tag{2.20}$$

with solutions $\tilde{\chi}_l(\rho) \sim e^{-\kappa_l\rho\sqrt{2}}$, which are finite for large ρ. This suggest to write

$$\tilde{\chi}_l(\rho) = \rho^{l+1}e^{-\kappa_l\rho\sqrt{2}}\tilde{w}_l(\rho) \tag{2.21}$$

---

[1] Typically we use the Hartree a.u.; when occasionally using the Rydberg a.u. this is explicitly indicated.

and search for a function $\tilde{w}_l(\rho)$ that allows us to connect the short-range expression of the wave function to the long-range one. The desired function must satisfy the condition $\tilde{w}_l(0) = 1$ and be algebraic for $r \to \infty$. Substituting the expression for $\tilde{\chi}_l(\rho)$ into Eq. (2.18) we obtain the following *nonlinear* differential equation for $\tilde{w}_l(\rho)$,

$$\rho\tilde{w}_l'' + 2[(l+1) - \sqrt{2}\,\kappa_l\rho]\tilde{w}_l' + 2[Z - (l+1)\sqrt{2}\,\kappa_l]\tilde{w}_l = 0. \tag{2.22}$$

Hence, the condition $\tilde{w}_l(0) = 1$ implies $\tilde{w}_l'(0) = \sqrt{2}\,\kappa_l\gamma/(l+1)$, where $\gamma \equiv (l+1) - Z/(\sqrt{2}\,\kappa_l)$. Dividing Eq. (2.22) by $2\sqrt{2}\,\kappa_l$ and turning to new variables, $\tilde{w}_l \to w_l$ and $\rho \to x$, where

$$w_l(x) = \tilde{w}_l(\rho) \quad \text{and } x = 2\sqrt{2}\,\kappa_l\rho, \tag{2.23}$$

we obtain the *Kummer equation*,

$$xw_l'' + [\beta - x]w_l' - \gamma w_l = 0, \tag{2.24}$$

where $\beta \equiv 2(l+1)$. The derivatives are now with respect to the variable x and the boundary conditions become $w_l(0) = 1$ and $w_l'(0) = \gamma/\beta$. For non-positive values of γ the solutions of Eq. (2.24) are confluent hypergeometric series (Kummer functions) [1]

$$w_l(x) = {}_1F_1(\gamma|\beta|x) = \sum_{p=0}^{\infty}\frac{\Gamma(\gamma+p)\Gamma(\beta)}{\Gamma(\gamma)\Gamma(\beta+p)}\frac{x^p}{p!} = 1 + \frac{\gamma}{\beta}\frac{x}{1!} + \frac{\gamma(\gamma+1)}{\beta(\beta+1)}\frac{x^2}{2!} + \cdots . \tag{2.25}$$

If γ is a non-positive integer, $\gamma(\kappa_{n'l}) = -n'$, this series turns into a polynomial of degree $n' \geq 0$

$$w_l(x) = {}_1F_1(-n'|\beta|x) = \sum_{p=0}^{n'}\frac{\Gamma(p-n')\Gamma(\beta)}{\Gamma(-n')\Gamma(\beta+p)}\frac{x^p}{p!}. \tag{2.26}$$

For non-integer values of γ the series is not truncated and has an essential singularity for $x \to \infty$. As we are only interested in normalizable wave functions it is conventional to use Laguerre polynomials of degree n' (see Appendix L.11) rather than Kummer functions,

$$w_l(x) = \frac{\Gamma(n'+1)\Gamma(\beta)}{\Gamma(\beta+n')}L_{n'}^{\beta-1}(x). \tag{2.27}$$

The truncation condition for the series, $\gamma(\kappa_{n'l}) = -n' \leq 0$, allows us to normalize the radial wave function and provides us with the quantization condition

$$\gamma(\kappa_{n'l}) = (l+1) - \frac{Z}{\sqrt{2}\,\kappa_{n'l}} = -n' \leq 0 \quad \Leftrightarrow \quad \sqrt{2}\,\kappa_{n'l} = \frac{Z}{n'+l+1}. \tag{2.28}$$

Note that the energy eigenvalues depend on two quantum numbers, n' and l. The integer n' is known as the *radial quantum number*. Its value corresponds to the number of zeros of the Laguerre polynomial; i.e., the number of nodes in the radial wavefunction outside the origin. In view of the experimental practice since the discovery of the *Balmer formula* in 1885 and the prominent role of the *Bohr theory* [17, 18, 19] since 1913, the radial quantum number is *not* used in the common scientific literature; preference is given to the *principal quantum number*, a historical mix of the quantum numbers n' and l,

$$n \equiv n' + l + 1. \tag{2.29}$$

Recalling the definitions (2.23) we find with the aid of Eq. (2.28) $x = 2Z\rho/n$. The radial wavefunction corresponding to the quantum numbers n and l is of the form

$$\tilde{R}_{nl}(\rho) = A_{nl}\rho^l e^{-Z\rho/n}w_l(2Z\rho/n), \tag{2.30}$$

where A_{nl} is a normalization constant. As $w_l(x)$ is a polynomial of degree $n' = n - l - 1 \geq 0$, the orbital angular momentum quantum number satisfies the condition

$$l \leq n - 1. \tag{2.31}$$

Since the formulation of the Bohr theory, electrons with the same principal quantum number are said to belong to the same *electron shell.* The shells are labeled $K, L, M, N, O, P, Q, \cdots$ in order of increasing principal quantum number $n = 1, 2, 3, \cdots$. Electrons sharing the same quantum numbers for n and l are called *equivalent electrons* and occupy a *(sub)shell.* Specifying the number of electrons per subshell one obtains the *electron configuration.* For example, with one electron in the $1s$ shell the configuration of hydrogenic atoms in their ground state is $(1s)^1$, usually abbreviated to $1s$.

2.2 Energy levels and degeneracy

In terms of the principal quantum number the quantization condition (2.28) takes the famous form of the *Bohr formula* [17],

$$\varepsilon = -\frac{Z^2}{2n^2} \text{ Hartree}, \tag{2.32}$$

with $n \geq 1$. Restoring the dimensions we obtain for the energy eigenvalues

$$E_n = -\alpha^2 m_r c^2 \frac{Z^2}{2n^2} = -\frac{\alpha^2 m_e c^2 Z^2}{1 + m_e/M} \frac{1}{2n^2} = -hcR_M \frac{Z^2}{n^2} = -\frac{Z^2}{n^2} \text{ Ry}. \tag{2.33}$$

Note that the atom has an infinite number of bound states. Writing $E_n \simeq \frac{1}{2} m_e \left\langle v^2 \right\rangle$ we infer that $\alpha^2 Z^2 \simeq \left\langle (v/c)^2 \right\rangle$. States with a large principal quantum number are called *Rydberg states* and atoms excited to those states are called *Rydberg atoms.* Eq. (2.33) defines the complete spectrum of the hydrogen atom according to the Schrödinger theory. It shows *degeneracy* of the energy levels, which means that different states have the same energy. For states of given l the degeneracy is $2l+1$ because the energy eigenvalues are independent of the the quantum number m_l. Degeneracies of this type are called *essential.* In contrast, degeneracies of states with different quantum numbers (e.g., states of given n but differing in l) are called *accidental.* With the condition $l \leq n - 1$ the degeneracy of the level E_n is given by the arithmetic series

$$\sum_{l=0}^{n-1} (2l + 1) = \tfrac{1}{2}[1 + (2n - 1)]n = n^2. \tag{2.34}$$

The atomic energy levels are illustrated in Fig. 2.1*a* along with the names of some well-known atomic transitions between hydrogenic levels: Lyman α (L_α) and Balmer-α (H_α). In the case of optically induced transitions the change in state of the atom is accompanied by a simultaneous change of the light field. This happens through exchange of a *photon* between the atom and field in such a way that the total energy and momentum are conserved. Energy-level diagrams discriminating between various quantum numbers (like in Fig. 2.1*a*) are often referred to as *Term diagrams.*[1] This practice finds its origin in the assignment of the energy levels in optical spectroscopy (see Fig. 2.1*b*) in which spectral lines are assigned to *terms* in a *series* of transitions sharing the same final (or initial) state. The first series of this type was discovered empirically by Balmer in 1885 for the spectral lines of hydrogen in the visible part of the spectrum. The *Balmer series* is defined by all optical excitations from (or decay to) the $n = 2$ level. Analogously, the *Lyman series* involves the transitions to (or from) the hydrogen ground state ($n = 1$). In 1888 Rydberg generalized the

---

[1] Term diagrams were introduced by the astrophysicist Walter Grotrian in 1928. The formal definition of the notion *Term* is given in Section 4.6.2.

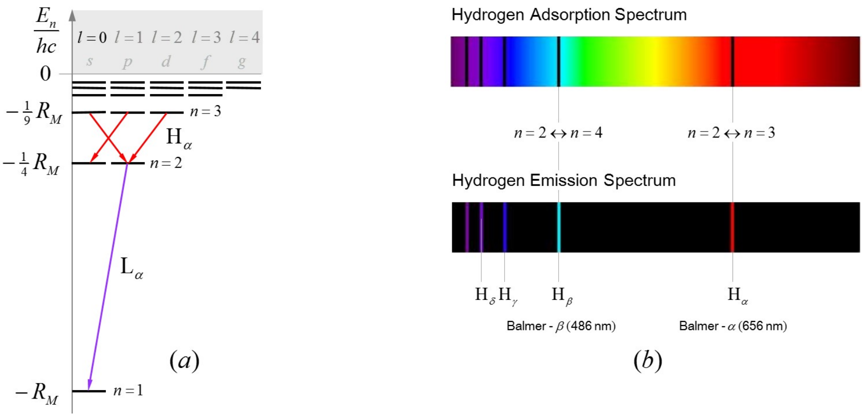

Figure 2.1: (a) Atomic energy level diagram (*Term diagram*) of hydrogen. Indicated are the first transitions of both the Lyman series (L_α) and the Balmer series (H_α). (b) Balmer spectrum of hydrogen observed in absorption (upper) and emission (lower).

expression for the Balmer series into the *Rydberg formula*, which yields the wavelength (in vacuum) of any transition between two hydrogenic energy levels,

$$\frac{1}{\lambda_n} = -R_M\left[\left(\frac{1}{n}\right)^2 - \left(\frac{1}{n_0}\right)^2\right], \tag{2.35}$$

where $n > n_0$, with n_0 being the principal quantum number of the common and lowest level in all transitions considered; i.e., the defining level of the series. The corresponding energy splitting is given by

$$\Delta E_n = E_n - E_0 = hc/\lambda_n. \tag{2.36}$$

If n_0 refers to an initial state, the atom is *excited* from the common level $E_0 \equiv E_{n_0}$ to one of the levels E_n under *absorption* of a photon of energy $\hbar\omega_n = E_n - E_0$.[1] In astronomy, such transitions are observed as dark lines in the spectrum of stellar light (see Fig. 2.1*b*-*upper*) and demonstrate the presence of *cold* (dark) interstellar gas between the observer and a distant star. Inversely, if n_0 refers to a final state, the atom is *de-excited* from one of the levels E_n to the level E_0 under *emission* of a photon of energy $\hbar\omega_n = E_n - E_0$. This is observed in spectroscopic studies of glowing *hot* interstellar clouds (in regions of star formation), where the emission appears as bright lines against a dark background in the spectrum of the glow (see Fig. 2.1*b*-*lower*).

2.3 Eigenfunctions of the bound states

Combining Eqs. (2.30) and (2.27) we find for the radial wavefunctions

$$\tilde{R}_{nl}(\rho) = \mathcal{N}_{nl}^{-1/2}(2Z/n)^{l+3/2}\rho^l e^{-Z\rho/n} L_{n-l-1}^{2l+1}(2Z\rho/n). \tag{2.37}$$

Note that the normalization factor A_{nl} used in Eq. (2.30) has been replaced by the normalization factor $\mathcal{N}_{nl}^{-1/2}$. Substituting this expression into Eq. (2.16) and changing to the variable $x = 2Z\rho/n$ we find with the aid of Eq. (L.83)

$$\mathcal{N}_{nl} = \int_0^\infty x^{2l+2}e^{-x}\left[L_{n-l-1}^{2l+1}(x)\right]^2 dx = J_1(n-l-1, 2l+1) = \frac{2n\Gamma(n+l+1)}{\Gamma(n-l)}. \tag{2.38}$$

---

[1] Here we neglect the *recoil shift*, a small shift of the optical transition frequency with respect to the value ω_n. It results from the conservation of linear momentum in the emission of a photon.

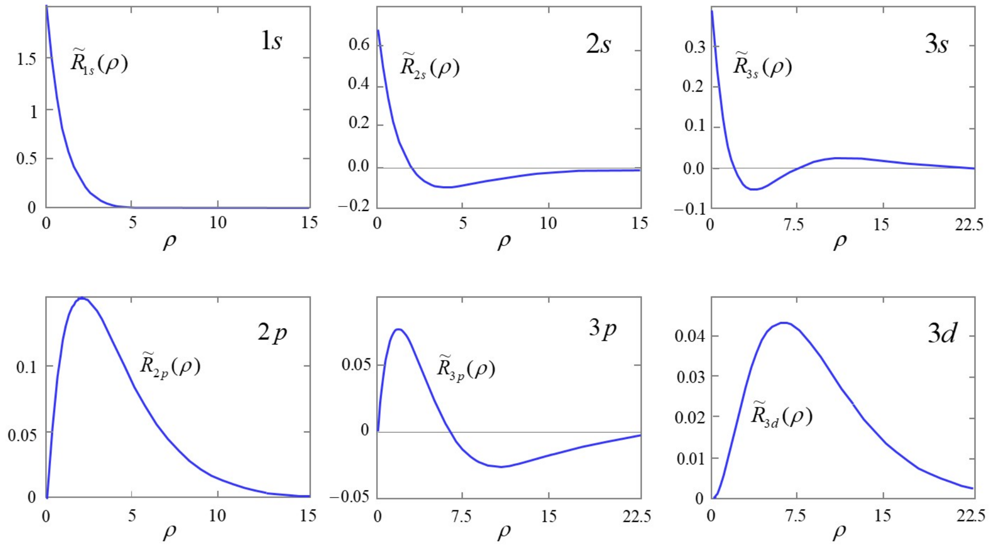

Figure 2.2: The lowest order hydrogenic radial wavefunctions plotted in atomic units as a function of radial distance. Note that for a given value of the orbital quantum number l the number of nodes increases with the principal quantum number n.

A few important cases are $\mathcal{N}_{1s} = 2$, $\mathcal{N}_{2p} = 24$, $\mathcal{N}_{3d} = 720$ and $\mathcal{N}_{4f} = 40320$. The integral $J_1(n-l-1, 2l+1)$ is a generalized normalization integral as defined by Eq. (L.81). Inspecting the solution Eq. (2.37), we find that $\tilde{\chi}_l(\rho) \sim \rho^n e^{-Z\rho/n}$ for $\rho \to \infty$. This is independent of l because asymptotically the Coulomb term, $2Z/\rho$, always dominates over the $-l(l+1)/\rho^2$ term in the Hamiltonian (all radial wave functions behave asymptotically as s waves). For $\rho \to 0$ the radial wavefunction vanishes for all values $l > 0$. For the case $l = 0$ the *probability density* (see Appendix F.1.1) of the radial wavefunction at the origin is

$$\tilde{R}^2_{ns}(0) = 4(Z/n)^3. \tag{2.39}$$

As an example we calculate the lowest hydrogenic radial wavefunctions for the cases $n = 1, 2, 3$ and arbitrary Z. The results for the hydrogen atom are obtained by setting $Z = 1$. Substituting the quantum numbers n and l into Eqs. (2.37) and (2.38) we find

$$\tilde{R}_{1s}(\rho) = Z^{3/2} 2e^{-Z\rho} \tag{2.40a}$$

$$\tilde{R}_{2s}(\rho) = (Z/2)^{3/2}\,(1 - Z\rho/2) 2e^{-Z\rho/2} \tag{2.40b}$$

$$\tilde{R}_{2p}(\rho) = (Z/2)^{3/2}\,\sqrt{1/3}(Z\rho/2) 2e^{-Z\rho/2} \tag{2.40c}$$

$$\tilde{R}_{3s}(\rho) = (Z/3)^{3/2}\left[1 - 2(Z\rho/3) + \tfrac{2}{3}(Z\rho/3)^2\right] 2e^{-Z\rho/3} \tag{2.40d}$$

$$\tilde{R}_{3p}(\rho) = (Z/3)^{3/2}\,\sqrt{8/9}\left[1 - \tfrac{1}{2}(Z\rho/3)\right] 2e^{-Z\rho/3} \tag{2.40e}$$

$$\tilde{R}_{3d}(\rho) = (Z/3)^{3/2}\,\sqrt{2/45}(Z\rho/3)^2 2e^{-Z\rho/3} \tag{2.40f}$$

In all cases $\int \tilde{R}^2_{nl}(\rho)\rho^2 d\rho = 1$. Some examples are shown (for $Z = 1$) in Fig. 2.2.

2.3.1 Dirac notation

In many cases it is convenient to adopt the Dirac notation $|nlm\rangle$ for the electronic orbital eigenstates of hydrogenic atoms. In this notation the Schrödinger equation (2.5) takes the compact form

$$\mathcal{H}_0\,|nlm\rangle = E_n\,|nlm\rangle\,. \tag{2.41}$$

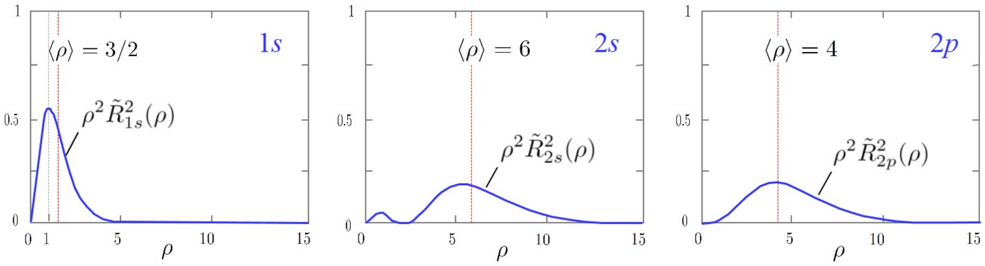

Figure 2.3: Radial distribution functions for the lowest hydrogenic wavefunctions. For the $1s$ wavefunction the radial distribution reaches a maximum at the Bohr radius ($\rho = 1$).

The relation with the eigenfunctions in the position representation is given by

$$\psi_{nlm}(\mathbf{r}) = \langle\mathbf{r}|nlm\rangle = \langle r|nl\rangle\langle\hat{\mathbf{r}}|lm\rangle, \tag{2.42}$$

with $\langle r|nl\rangle = rR_{nl}(r)$ and $\langle\hat{\mathbf{r}}|lm\rangle = Y_l^m(\hat{\mathbf{r}})$.

2.4 Diagonal matrix elements

2.4.1 Radial averages

The expectation value of an operator A for an atom in eigenstate $|nlm\rangle$ is given by

$$\langle A\rangle \equiv \langle nlm|A|nlm\rangle\,. \tag{2.43}$$

In many cases of practical importance the operator A depends analytically on the radial distance to the nucleus, $A = A(\rho)$. Operators of this type are *diagonal* in the representation $\{|nlm\rangle\}$. Importantly, $\langle A\rangle$ separates into the product of a radial and an angular integral,[1]

$$\langle A\rangle_{nlm} = \int d\rho\,\rho^2\tilde{R}_{nl}(\rho)A(\rho)\tilde{R}_{nl}(\rho)\int |Y_l^m(\Omega)|^2\,d\Omega, \tag{2.44}$$

which reduces, given the normalization of the spherical harmonics, to a purely radial integral,

$$\langle A\rangle_{nlm} = \int d\rho\,A(\rho)\tilde{\chi}^2_{nl}(\rho) = \langle A\rangle_{nl}. \tag{2.45}$$

Here $\tilde{\chi}_{nl}(\rho)$ is a *reduced radial wavefunction* as introduced in Section 1.2.1. By separating the radial from the angular integral we obtain a *reduced matrix element*; i.e., it depends on n and l but *not* on m (see Problem 2.2). Like an ordinary matrix element it is an integral over the radial variable but differs by the presence of the additional weight factor ρ^2. The function

$$\tilde{\chi}^2_{nl}(\rho) = \rho^2\tilde{R}^2_{nl}(\rho) \tag{2.46}$$

is called the *radial distribution function* of the state $|nl\rangle$ and expresses the radial distribution of the probability density to find the electron at distance ρ from the origin. For the lowest radial wavefunctions these are shown in Fig. 2.3.

---

[1] In these lecture notes we use interchangeable notations for the radial unit vector: $\hat{\mathbf{r}} \equiv \Omega \equiv (\theta, \phi)$.

2.4.1.1 Atomic size

As a first example we calculate the average radius of the hydrogen ground state $|1s\rangle$ with the aid of Eq. (2.40a),

$$\langle\rho\rangle_{1s} = \int \rho[2\rho e^{-\rho}]^2 d\rho = 4\int \rho^3 e^{-2\rho} d\rho = \tfrac{1}{4}\int x^3 e^{-x} dx = \tfrac{1}{4}\Gamma(4) = \tfrac{3}{2}. \tag{2.47}$$

Comparing with Eq. (2.10) we find that $\langle r\rangle_{1s} = \frac{3}{2}a$, which is 50% larger than the Bohr radius, $a_0 \simeq 5.2 \times 10^{-11}$ m. As the proton size is orders of magnitude smaller, $r_p \simeq 8.8 \times 10^{-16}$ m, this justifies in hindsight our Ansatz of treating the nucleus as a point charge. Compact relations for the radial averages $\langle\rho^k\rangle_{nl}$ in atomic units can be obtained by expressing Eq. (2.44) in terms of the integrals $J_\nu(n', 2l+1)$ defined in Eq. (L.81),

$$\begin{aligned}\langle\rho^k\rangle_{nl} &= \frac{1}{\mathcal{N}_{nl}}\left(\frac{n}{2Z}\right)^k \int_0^\infty x^{2l+2+k} e^{-x}\left[L_{n-l-1}^{2l+1}(x)\right]^2 dx \\ &= \left(\frac{n}{2Z}\right)^k \frac{J_{k+1}(n-l-1, 2l+1)}{J_1(n-l-1, 2l+1)}.\end{aligned} \tag{2.48}$$

In particular we obtain for a number of important special cases with the aid of Eqs. (L.82)-(L.85)

$$\langle\rho\rangle_{nl} = \frac{1}{2Z}[3n^2 - l(l+1)] \qquad \langle\rho^{-1}\rangle_{nl} = \frac{Z}{n^2} \tag{2.49a}$$

$$\langle\rho^2\rangle_{nl} = \frac{1}{2Z^2}n^2[5n^2 + 1 - 3l(l+1)] \qquad \langle\rho^{-2}\rangle_{nl} = \frac{Z^2}{n^3}\frac{1}{l+1/2} \tag{2.49b}$$

$$\langle\rho^{-3}\rangle_{nl} = \frac{Z^3}{n^3}\frac{1}{(l+1)(l+1/2)\,l}. \tag{2.49c}$$

By substituting $n = 1$, $l = 0$, $Z = 1$ we regain the result $\langle r\rangle = 3/2a$ for the average radius of the hydrogen ground state in atomic units. With Eqs. (2.49a) and (2.49b) the variance in the radial position is calculated to be

$$\langle(\rho - \langle\rho\rangle)^2\rangle_{nl} = \langle\rho^2\rangle_{nl} - \langle\rho\rangle_{nl}^2 = \frac{1}{4Z^2}\left[n^2(n^2+2) - l^2(l+1)^2\right]. \tag{2.50}$$

As another example of a radial average we calculate the average radial kinetic energy for the hydrogen ground state $|100\rangle$ in Hartree atomic units

$$\begin{aligned}\left\langle -\frac{1}{2\rho}\frac{\partial^2}{\partial\rho^2}\rho\right\rangle_{1s} &= -2\int d\rho\, \rho e^{-\rho}\frac{d^2}{d\rho^2}(\rho e^{-\rho}) \\ &= 4\int \rho e^{-2\rho} d\rho - 2\int \rho^2 e^{-2\rho} d\rho = \Gamma(2) - \tfrac{1}{4}\Gamma(3) = \tfrac{1}{2}.\end{aligned} \tag{2.51}$$

This expression may be generalized for arbitrary hydrogenic eigenstates (see Problem 2.3).

Problem 2.2. Show that Eq. (2.45) is a reduced matrix element in the sense of the Wigner-Eckart theorem (cf. Appendix K.2).

Solution. The scalar operator $A(\rho)$ is an irreducible tensor operator of rank zero. Using the sum rule of Appendix K.2.1 the reduced matrix element is given by

$$|\langle nl||A||nl\rangle|^2 = \sum_{m=-l}^{l} |\langle nlm|A|nlm\rangle|^2.$$

Substituting Eq. (2.45) we have $2l+1$ equal terms and obtain

$$\langle A\rangle_{nl}^2 = |\langle nl||A||nl\rangle|^2/(2l+1),$$

which is independent m and, as such, a reduced matrix element in the sense of the Wigner-Eckart theorem. For zero-order tensors the use of this theorem is overkill because the angular integral not only factors out of the integral but evaluates to unity - see derivation of Eq. (2.45). □

Problem 2.3. Show that the radial kinetic energy of the state $|nlm\rangle$ is given by

$$\left\langle -\frac{1}{2\rho}\frac{\partial^2}{\partial\rho^2}\rho\right\rangle_{nl} = \frac{Z^2}{n^2}\left[\frac{1}{2} - \frac{l\,(l+1)}{n\,(2l+1)}\right] \text{ a.u..} \tag{2.52}$$

Solution. Changing to the variable $x = 2Z\rho/n$ we have

$$\tilde{R}_{nl}^2(\rho)\rho^2 d\rho = \mathcal{N}_{nl}^{-1} x^{2l+2} e^{-x} \left[L_{n-l-1}^{2l+1}(x)\right]^2 dx$$

and after angular integration we are left with the radial average,

$$\left\langle -\frac{1}{2\rho}\frac{\partial^2}{\partial\rho^2}\rho\right\rangle_{nl} = -\frac{1}{2\mathcal{N}_{nl}}\left(\frac{2Z}{n}\right)^2 \int_0^\infty x^{l+1}e^{-x/2}L_{n-l-1}^{2l+1}(x)\frac{d^2}{dx^2}[x^{l+1}e^{-x/2}L_{n-l-1}^{2l+1}(x)]dx.$$

In view of the orthogonality relation (L.76) we have to retain only those derivatives which are proportional to $\left[L_{n-l-1}^{2l+1}(x)\right]^2$,

$$\left[L_{n-l-1}^{2l+1}(x)\right]^2 x^{l+1}e^{-x/2}\tfrac{d^2}{dx^2}x^{l+1}e^{-x/2} = x^{2l+1}e^{-x}\left(l(l+1)x^{-1} - (l+1) + \tfrac{1}{4}x\right)\left[L_{n-l-1}^{2l+1}(x)\right]^2$$

$$-L_{n-l-1}^{2l+1}(x)\textstyle\sum_{m=0}^{n-l-2} L_m^{2l+1}(x)\left[2x^{l+1}e^{-x/2}\tfrac{d}{dx}x^{l+1}e^{-x/2}\right] \to -x^{2l+1}e^{-x}\,(n-l-1)\left[L_{n-l-1}^{2l+1}(x)\right]^2$$

$$L_{n-l-1}^{2l+1}(x)\textstyle\sum_{m=0}^{n-l-2} lL_m^{2l+1}(x)\left(x^{l+1}e^{-x/2}\right)^2 \to 0.$$

Here we used the expansions (L.80b) and (L.80c). Collecting the selected terms we obtain

$$\begin{aligned}\left\langle -\frac{1}{2\rho}\frac{\partial^2}{\partial\rho^2}\rho\right\rangle_{nl} &= -\frac{2}{\mathcal{N}_{nl}}\frac{Z^2}{n^2}\int_0^\infty x^{2l+1}e^{-x}\left[L_{n-l-1}^{2l+1}(x)\right]^2\left(l(l+1)x^{-1} - n + \frac{1}{4}x\right)dx \\ &= \frac{Z^2}{n^2}\left\{-2l(l+1)\frac{J_{-1}(n-l-1,2l+1)}{J_1(n-l-1,2l+1)} + 2n\frac{J_0(n-l-1,2l+1)}{J_1(n-l-1,2l+1)} - \frac{1}{2}\right\}.\end{aligned}$$

Substituting the expressions for the $J_\nu(m,\alpha)$ from Appendix L.11 we find Eq. (2.52). □

2.4.2 Angular averages

Angular distributions can be written as an expansion over spherical harmonics $Y_k^q(\hat{\mathbf{r}})$ for which the angular averages are easily calculated using the Gaunt integral (L.59),

$$\begin{aligned}\langle Y_k^q(\hat{\mathbf{r}})\rangle_{lm} &\equiv \langle lm|Y_k^q(\hat{\mathbf{r}})|lm\rangle \\ &= \int Y_k^q(\hat{\mathbf{r}})\,|Y_l^m(\hat{\mathbf{r}})|^2\,d\hat{\mathbf{r}} \qquad (2.53)\\ &= (-1)^m\,(2l+1)\sqrt{\frac{(2k+1)}{4\pi}}\begin{pmatrix} l\,k\,l \\ 0\,0\,0\end{pmatrix}\begin{pmatrix} l & k & l \\ -m & q & m\end{pmatrix}. \qquad (2.54)\end{aligned}$$

This average is *non-zero only* for $q=0$ and $k=$ *even* in the interval $0\le k\le 2l$. See Eq. (J.21) and the selection rules for $3j$ symbols.

2.4.2.1 Examples

The angular averages of the lowest-order spherical harmonics are found by using the expressions for the Wigner $3j$ symbols - see Eq. (L.59),

$$\langle lm|Y_0^0(\hat{\mathbf{r}})|lm\rangle = \sqrt{\frac{1}{4\pi}} \qquad (2.55a)$$

$$\langle lm|Y_1^0(\hat{\mathbf{r}})|lm\rangle = 0 \qquad (2.55b)$$

$$\langle lm|Y_2^0(\hat{\mathbf{r}})|lm\rangle = \frac{l\,(l+1)-3m^2}{(2l+3)(2l-1)}\sqrt{\frac{5}{4\pi}}. \qquad (2.55c)$$

Problem 2.4. Show that for s orbitals $\langle lm|Y_k^q(\hat{\mathbf{r}})|lm\rangle$ is non-zero only for $k=q=0$.

Solution. To calculate the angular average of $Y_k^q(\hat{\mathbf{r}})$ we use Eq. (2.54). The angular average is nonzero if the $3j$ symbols are nonzero; i.e., for $0\le k\le 2l$. For s orbitals ($l=0$) this implies $0\le k\le 0$. Hence, for $k>0$ the angular averages all vanish. For $k=0$ we find

$$\langle 00|Y_0^0(\hat{\mathbf{r}})|00\rangle = \sqrt{1/4\pi}\langle 00|00\rangle = \sqrt{1/4\pi}. \qquad \square$$

Problem 2.5. Show that the s-wave angular average of $\sin^2\theta$ is $\langle 00|\sin^2\theta|00\rangle = 2/3$.

Solution. First we express $\sin^2\theta$ in spherical harmonics

$$\sin^2\theta = \frac{2}{3}-\frac{2}{3}\sqrt{\frac{4\pi}{5}}Y_2^0(\theta,\phi)$$

Then the angular average follows with Eq. (2.55c),

$$\langle lm|\sin^2\theta|lm\rangle = \frac{2}{3}-\frac{2}{3}\frac{l\,(l+1)-3m^2}{(2l+3)(2l-1)}.$$

For s waves ($l=m=0$) this yields $2/3$. It may speak for itself that there are simpler ways to average $\sin^2\theta$ over a sphere. This problem merely serves to demonstrate the general case. □

2.5 Off-diagonal matrix elements

2.5.1 Transition dipole matrix elements

In this section we investigate the matrix elements $\langle n'l'm'|\,\mathbf{d}\,|nlm\rangle$ of the *electric-dipole operator*

$$\mathbf{d} = -\,e\mathbf{r} = -\,ea\rho\,\hat{\mathbf{r}} \qquad (2.56)$$

between eigenstates of the Schrödinger Hamiltonian. The electric-dipole operator has odd *parity*; i.e., the operator changes sign when replacing the radius vector $\mathbf{r}$ by $-\mathbf{r}$. Since the electronic eigenstates carry the parity of the $Y_l^m(\hat{\mathbf{r}})$ - see Eq. (L.53) - the expectation value of the electric-dipole operator averages to zero, $\langle nlm|\mathbf{d}|nlm\rangle = 0$. This reflects the absence of a *permanent electric-dipole moment* for hydrogenic eigenstates.[1] Hence, the atomic-dipole matrix is off-diagonal.

The off-diagonal matrix element

$$\mathbf{D}_{eg} = \langle e|\,\mathbf{d}\,|g\rangle \tag{2.57}$$

is called the *transition-dipole moment* of the $e \leftrightarrow g$ transition between atomic states. As $\mathbf{D}_{eg}$ is generally a complex vector it may be written as the product of a *generally complex* unit vector $\hat{\mathbf{u}}$ and a *real* prefactor D_{eg},

$$\mathbf{D}_{eg} = D_{eg}\hat{\mathbf{u}}. \tag{2.58}$$

Because the dipole operator is hermitian,[2] $\mathbf{D}_{eg} = \mathbf{D}_{ge}^*$, we have

$$|\mathbf{D}_{eg}|^2 = |\mathbf{D}_{ge}|^2 = D_{eg}^2. \tag{2.59}$$

With regard to the eigenstates $|g\rangle = |nlm\rangle$ and $|e\rangle = |n'l'm'\rangle$ of hydrogenic atoms, the transition dipole moment is given by

$$\mathbf{D}_{n'l'm',nlm} = -ea\langle n'l'm'|\rho\,\hat{\mathbf{r}}\,|nlm\rangle\,. \tag{2.60}$$

Decomposing the hydrogenic wavefunctions into the product of radial and angular states, $\psi_g(\mathbf{r}) = R_{nl}(r)Y_l^m(\hat{\mathbf{r}})$, the matrix elements of the transition dipole separate into a radial and an angular contribution,

$$\mathbf{D}_{n'l'm',nlm} = -ea\mathcal{R}_{n'l',nl}\,\langle l'm'|\,\hat{\mathbf{r}}\,|lm\rangle\,. \tag{2.61}$$

The radial contribution is given by the integral - compare with Eq. (2.45)

$$\mathcal{R}_{n'l',nl} \equiv \int_0^\infty \tilde{\chi}_{n'l'}\rho\tilde{\chi}_{nl}(\rho)d\rho. \tag{2.62}$$

Note the property

$$\mathcal{R}_{n'l',nl} = \mathcal{R}_{nl,n'l'}. \tag{2.63}$$

The angular contribution is given by

$$\langle l'm'|\,\hat{\mathbf{r}}\,|lm\rangle = \int Y_{l'}^{m'*}(\hat{\mathbf{r}})\,\hat{\mathbf{r}}\,Y_l^m(\hat{\mathbf{r}})d\hat{\mathbf{r}}. \tag{2.64}$$

Note that this integral is zero if the parity of the integrand is odd. This reveals that the electric-dipole transition requires a *change of parity* of the electronic state.

2.5.2 Angular matrix element - spherical basis

To find an explicit expression for the angular matrix element we decompose the radial unit vector $\hat{\mathbf{r}}$, as defined in Eq. (1.13a), in the *spherical basis*[3]

$$\hat{\mathbf{r}} = \sqrt{4\pi/3}\left[\hat{\mathbf{u}}_{+1}^*Y_1^1(\hat{\mathbf{r}}) + \hat{\mathbf{u}}_{-1}^*Y_1^{-1}(\hat{\mathbf{r}}) + \hat{\mathbf{u}}_0^*Y_1^0(\hat{\mathbf{r}})\right], \tag{2.65}$$

where the *spherical* unit vectors are defined by

$$\hat{\mathbf{u}}_{+1} = -\sqrt{\tfrac{1}{2}}(\hat{\mathbf{x}} + i\hat{\mathbf{y}}), \qquad \hat{\mathbf{u}}_{-1} = +\sqrt{\tfrac{1}{2}}(\hat{\mathbf{x}} - i\hat{\mathbf{y}}), \qquad \hat{\mathbf{u}}_0 = \hat{\mathbf{z}}. \tag{2.66}$$

---

[1] States sharing the same principal quantum number but differing in orbital angular momentum are degenerate in the case of the Schrödinger Hamiltonian. Linear combinations of such states do have a permanent electric dipole moment. This moment becomes nonstationary when the degeneracy is lifted by some perturbation.

[2] Note that $\langle\mathbf{r}|\underline{\mathbf{r}}|\mathbf{r}'\rangle^* = \mathbf{r}'\delta(\mathbf{r}'-\mathbf{r}) = \mathbf{r}\delta(\mathbf{r}-\mathbf{r}') = \langle\mathbf{r}'|\underline{\mathbf{r}}|\mathbf{r}\rangle$.

[3] This is readily verified: $\hat{\mathrm{u}}_{\pm1}\cdot\mathbf{r} = \mp\sqrt{1/2}\,[(\hat{\mathrm{x}}\cdot\mathbf{r}) \pm i(\hat{\mathrm{y}}\cdot\mathbf{r})] = \mp r\sqrt{1/2}\,e^{\pm i\phi}\sin\theta$; $\hat{\mathrm{u}}_0\cdot\mathbf{r} = \hat{\mathrm{z}}\cdot\mathbf{r} = r\cos\theta$.

The decomposition (2.65) is called the *standard decomposition* or *spherical decomposition* of the radial unit vector $\hat{\mathbf{r}}$. Substituting Eqs. (2.66) into Eq. (2.65) we regain the *cartesian decomposition* of $\hat{\mathbf{r}}$ as given in Eq. (1.13a). The orthonormality relations for the spherical unit vectors are

$$\hat{\mathbf{u}}_i^* \cdot \hat{\mathbf{u}}_j = \delta_{ij} \tag{2.67}$$

with $i, j \in \{-1, 0, 1\}$. Note that $\hat{\mathbf{u}}_{+1} = -\hat{\mathbf{u}}_{-1}^*$, $\hat{\mathbf{u}}_{-1} = -\hat{\mathbf{u}}_{+1}^*$ and $\hat{\mathbf{u}}_0 = \hat{\mathbf{u}}_0^*$, which is summarized by the expression

$$\hat{\mathbf{u}}_q = (-1)^q \hat{\mathbf{u}}_{-q}^*. \tag{2.68}$$

The reverse transformation is given by

$$\hat{\mathbf{x}} = -\sqrt{\tfrac{1}{2}}(\hat{\mathbf{u}}_{+1} - \hat{\mathbf{u}}_{-1}), \qquad \hat{\mathbf{y}} = +\sqrt{\tfrac{1}{2}}(\hat{\mathbf{u}}_{+1} + \hat{\mathbf{u}}_{-1})\, i, \qquad \hat{\mathbf{z}} = \hat{\mathbf{u}}_0. \tag{2.69}$$

The angular matrix element is readily evaluated in the spherical decomposition. Using the integral for the product of three spherical harmonics, see Eq. (L.59), we obtain

$$\begin{aligned} \langle l'm'|\, \hat{\mathbf{r}}\, |lm\rangle &= \textstyle\sum_{q=-1}^{1} \hat{\mathbf{u}}_q^* \, \langle l'm'|\, \sqrt{4\pi/3}\, Y_1^q(\hat{\mathbf{r}})\, |lm\rangle \\ &= \textstyle\sum_{q=-1}^{1} \hat{\mathbf{u}}_q^* \, (-1)^{m'+\max(l,l')} \sqrt{\max(l,l')} \begin{pmatrix} l' & 1 & l \\ -m' & q & m \end{pmatrix} \delta_{l',l\pm1} \\ &= \hat{\mathbf{u}}_{m'-m}^* \mathcal{A}_{l'm',lm}, \end{aligned} \tag{2.70}$$

where the prefactor of the angular integral and given by

$$\mathcal{A}_{l'm',lm} = (-1)^{m'+\max(l,l')} \sqrt{\max(l,l')} \begin{pmatrix} l' & 1 & l \\ -m' & m'-m & m \end{pmatrix} \delta_{l',l\pm1}. \tag{2.71}$$

Note the property

$$\mathcal{A}_{l'm',lm} = (-1)^{m'-m} \mathcal{A}_{lm,l'm'}. \tag{2.72}$$

The last step in Eq. (2.70) follows from the projection rule of $3j$ symbols, $q + m - m' = 0$, which implies that *only one* of the three terms of the spherical decomposition gives a nonzero contribution to the matrix element $\langle l'm'|\, \hat{\mathbf{r}}\, |lm\rangle$. This selection rule expresses the conservation of angular momentum along the quantization axis. The factor $\delta_{l',l\pm1}$ expresses the *electric-dipole parity selection rule* for one-electron atoms,

$$l' = l \pm 1. \tag{2.73}$$

2.5.3 Transition dipole and transition strength

Thus we established that the transition dipole can be written in the general form (2.58),

$$\mathbf{D}_{n'l'm',nlm} = D_{n'l'm',nlm} \hat{\mathbf{u}}_{m'-m}^*, \tag{2.74}$$

where $\hat{\mathbf{u}}_{m'-m}^*$ is a *spherical unit vector* and

$$D_{n'l'm',nlm} = -ea\, \mathcal{R}_{n'l',nl} \mathcal{A}_{l'm',lm}. \tag{2.75}$$

The quantity

$$|\mathbf{D}_{n'l'm',nlm}|^2 = D_{n'l'm',nlm}^2 = e^2 a^2 \mathcal{R}_{n'l',nl}^2 \mathcal{A}_{l'm',lm}^2 \tag{2.76}$$

is called the $n'l'm' \leftrightarrow nlm$ (atomic-dipole) *transition strength*. Note that $D_{n'l'm',nlm}$ can be written in the form

$$D_{n'l'm',nlm} = -ea\, \langle n'l'm'|\, \sqrt{4\pi/3}\, \rho\, Y_1^{(m'-m)}(\hat{\mathbf{r}})\, |nlm\rangle\,. \tag{2.77}$$

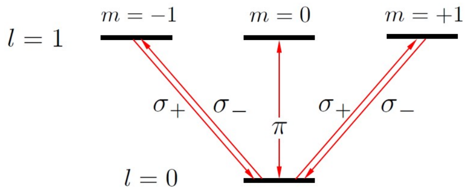

Figure 2.4: Depending on the change in magnetic quantum number of the atom, electric-dipole transitions are referred to as *sigma-plus* ($\Delta m = 1$), *sigma-minus* ($\Delta m = -1$) or *pi* ($\Delta m = 0$) transitions.

As the operator $\sqrt{4\pi/3}\, r\, Y_1^{(m'-m)}(\hat{\mathbf{r}})$ is a standard component of the irreducible vector operator $\mathbf{r}$ (cf. Section 2.5.2 and Appendix K.1.2) we can apply the Wigner-Eckart theorem (K.24),

$$D_{n'l'm',nlm} = -ea\,(-1)^{l'-m'}\langle n'l'||\sqrt{4\pi/3}\,\rho\, Y_1(\hat{\mathbf{r}})||nl\rangle \begin{pmatrix} l' & 1 & l \\ -m' & m'-m & m \end{pmatrix}. \tag{2.78}$$

Comparing Eqs. (2.78) with (2.75) and (2.71) we obtain *once and for all* the expression for the reduced matrix element in the standard representation $\{L^2, L_z\}$

$$\langle n'l'||\sqrt{4\pi/3}\,\rho\, Y_1(\hat{\mathbf{r}})||nl\rangle = \pm\sqrt{\max(l,l')}\,\delta_{l',l\pm1}\mathcal{R}_{n'l',nl}. \tag{2.79}$$

2.5.4 Selection rules for electric-dipole transitions - spin of the photon

Since $e^2a^2\mathcal{R}^2_{n'l',nl}$ is positive-definite, the transition-dipole is only non-zero if $\mathcal{A}_{l'm',lm}$ is non-zero; i.e., if the condition

$$\begin{pmatrix} l' & 1 & l \\ -m' & m'-m & m \end{pmatrix}\delta_{l',l\pm1} \neq 0 \tag{2.80}$$

is satisfied. The parity selection rule (2.73) is enforced by the Kronecker symbol $\delta_{l',l\pm1}$. Together with the properties of the $3j$ symbol Eq. (2.80) yields the *selection rules* for electric-dipole transitions

$$\Delta l = \pm 1, \qquad \Delta m = 0, \pm 1, \tag{2.81}$$

where $\Delta l = l' - l$ and $\Delta m = m' - m$. Transitions in which the magnetic quantum number increases (decreases) are called σ_+ (σ_-) transitions; transitions with $\Delta m = 0$ are called π transitions (see Fig. 2.4).

If the transition is induced by the electromagnetic field, the change in angular momentum of the atom is compensated by a change in angular momentum of the field (to conserve the total angular momentum). This happens in the exchange of a *photon* between atom and field. From the selection rule $\Delta l = \pm 1$ we infer that the emitted (or absorbed) photon always carries a single unit of angular momentum. This angular momentum is called the *spin of the photon* ($s = 1$). From the selection rule $\Delta m = 0, \pm 1$ we infer that the quantum number m_s for the *projection of the photon spin* on the quantization axis of the atom is given by $m_s = \Delta m = 0, \pm 1$. The probability to observe the photon as a particle with *polarization* unit vector $\hat{\epsilon}$ is given by $|\hat{\epsilon}\cdot\hat{\mathbf{u}}^*_{m'-m}|^2$. Further discussion of optical transitions is best given after the interaction of atoms with the electromagnetic field has been introduced.

2.5.5 Examples of electric-dipole transitions in hydrogen:

2.5.5.1 Lyman transitions:

Let us calculate the radial and angular integrals for a couple of important cases. First we consider excitation from (or decay to) the electronic ground state ($np \leftrightarrow 1s$). These transitions define the

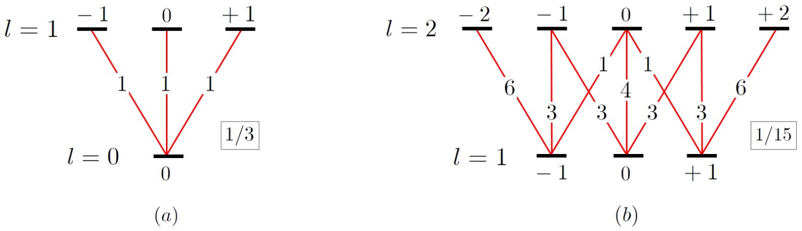

Figure 2.5: Angular contribution to the transition strength for: (a) sp transitions; (b) pd transitions. The squared angular matrix element of the reference transition (the weakest of the set) is 1/3 (for sp) and 1/15 (for dp). Note that the sum of the transition probabilities is the same for all upper (or lower) levels.

Lyman series. Setting $l = 0$ in Eq. (2.80) the selection rule for these transitions becomes

$$\begin{pmatrix} l' & 1 & 0 \\ -m' & m' & 0 \end{pmatrix} \neq 0. \tag{2.82}$$

In other words we require $l' = 1$ and $m' = -1, 0, 1$.

Substituting the expressions for $\tilde{R}_{1s}(\rho)$ and $\tilde{R}_{np}(\rho)$ from Eq. (2.37) into the radial integral (2.62) and changing to the variable $x = 2Z\rho/n$ the radial integral becomes

$$\mathcal{R}_{np,1s} \equiv \frac{1}{Z}\sqrt{\frac{(n-2)!}{(n+1)!}}\left(\frac{n}{2}\right)^2 \int x^4 e^{-(n+1)x/2} L^3_{n-2}(x)dx. \tag{2.83}$$

This integral is evaluated by repetitive use (3×) of the recursion relation (L.80a),

$$\int x^4 e^{-(n+1)x/2} L^3_{n-2}(x)dx = \sum_{n'=0}^{n-2}\sum_{n''=0}^{n'}\sum_{k=0}^{n''}\int x^4 e^{-(n+1)x/2} L_k(x)dx. \tag{2.84}$$

Note that the number of recursions required is equal to the upper index of the Laguerre polynomial. Evaluating the integral and summations we obtain

$$\mathcal{R}_{np,1s} = (1/Z)2^4 n^{7/2}\frac{(n-1)^{n-5/2}}{(n+1)^{n+5/2}} \qquad n \geq 2. \tag{2.85}$$

The angular integral yields (see also Fig. 2.5a)

$$\mathcal{A}_{p\to s} = \mathcal{A}_{1m',00} = (-1)^{m'+1}\begin{pmatrix} 1 & 1 & 0 \\ -m' & m' & 0 \end{pmatrix} = \sqrt{\tfrac{1}{3}}. \tag{2.86}$$

In particular we find for the Lyman α transition strength ($2p_{m'} \leftrightarrow 1s$) - see Problem 2.6

$$D^2_{2p,1s} = 0.554\,93\, e^2a^2/Z^2. \tag{2.87}$$

Note that this results holds for transitions is independent of the choice of m'.

2.5.5.2 Balmer transitions:

The second example is the Balmer series, which is defined by *excitation from* (or decay to) the first excited electronic state ($n = 2$ level).

$np \leftrightarrow 2s$ transitions ($n \geq 2$)
Substituting the expressions for $\tilde{R}_{2s}(\rho)$ and $\tilde{R}_{np}(\rho)$ from Eq. (2.37) into the radial integral (2.62) and changing to the variable $x = 2Z\rho/n$ the radial integral becomes

$$\mathcal{R}_{np,2s} \equiv \frac{1}{2Z\sqrt{2}}\sqrt{\frac{(n-2)!}{(n+1)!}}\left(\frac{n}{2}\right)^2 \int x^4(1-nx/4)e^{-(n+2)x/4}L^3_{n-2}(x)dx. \tag{2.88}$$

The integral is evaluated by repetitive use (3×) of the recursion relation (L.80a),

$$\int x^4(1-nx/4)e^{-(n+2)x/4}L^3_{n-2}(x)dx = \sum_{n'=0}^{n-2}\sum_{n''=0}^{n'}\sum_{k=0}^{n''}\int x^4(1-nx/4)e^{-(n+2)x/4}L_k(x)dx. \tag{2.89}$$

Evaluating the integral and summations we obtain

$$\mathcal{R}_{np,2s} = \begin{cases} -(1/Z)3\sqrt{3} & n=2 \\ +(1/Z)2^8\sqrt{2}\,n^{7/2}(n^2-1)^{1/2}\dfrac{(n-2)^{n-3}}{(n+2)^{n+3}} & n>2. \end{cases} \tag{2.90}$$

The angular integral yields for all sp transitions (see also Fig. 2.5a)

$$\mathcal{A}_{p\to s} = \mathcal{A}_{1m',00} = (-1)^{m'+1}\begin{pmatrix} 1 & 1 & 0 \\ -m' & m' & 0 \end{pmatrix} = \sqrt{\tfrac{1}{3}}. \tag{2.91}$$

In particular we find for $n = 3$ the $2s \leftrightarrow 3p$ contribution to the Balmer-α transition strength,

$$D^2_{3p,2s} = 3.131\, e^2a^2/Z^2. \tag{2.92}$$

$ns \leftrightarrow 2p$ transitions
Substituting the expressions for $\tilde{R}_{2p}(\rho)$ and $\tilde{R}_{ns}(\rho)$ from Eq. (2.37) into the radial integral (2.62) and changing to the variable $x = 2Z\rho/n$ the radial integral becomes

$$\mathcal{R}_{ns,2p} \equiv \frac{1}{32Z\sqrt{6}}n^{5/2}\int x^4 e^{-(n+2)x/4}L^1_{n-1}(x)dx. \tag{2.93}$$

The integral is evaluated with the aid of the recursion relation (L.80a),

$$\int x^4 e^{-(n+2)x/4}L^1_{n-1}(x)dx = \sum_{k=0}^{n-1}\int x^4 e^{-(n+2)x/4}L_k(x)dx. \tag{2.94}$$

Evaluating the integral and summations we obtain[1]

$$\mathcal{R}_{ns,2p} = \begin{cases} -(1/Z)3\sqrt{3} & n=2 \\ +(1/Z)2^7\sqrt{2/3}\,n^{9/2}\dfrac{(n-2)^{n-3}}{(n+2)^{n+3}} & n\neq 2. \end{cases} \tag{2.95}$$

The angular integral yields for all sp transitions (see also Fig. 2.5a)

$$\mathcal{A}_{00,1m} = (-1)^{m+1}\begin{pmatrix} 0 & 1 & 1 \\ 0 & -m & m \end{pmatrix} = \sqrt{\tfrac{1}{3}}. \tag{2.96}$$

Note that for $n = 1$ we regain the $1s \leftrightarrow 2p_m$ (Lyman α) transition strength - see Eq. (2.87)

$$D^2_{2p,1s} = e^2a^2\mathcal{R}^2_{1s,2p}\mathcal{A}^2_{00,1m} = 0.554\,93\, e^2a^2/Z^2. \tag{2.97}$$

---

[1] For $n = 1$ the transition is part of the Lyman series - compare with Eq. (2.85).

Likewise, we find for $n = 3$ the $3s \leftrightarrow 2p_{m'}$ Balmer-α transition strength,

$$D^2_{3s,2p_m} = e^2 a^2 \mathcal{R}^2_{3s,2p} \mathcal{A}^2_{00,1m} = 0.293\,53\, e^2 a^2/Z^2. \tag{2.98}$$

A new aspect comes into play when dealing with incoherent sums over (initial or final) states. A well-known example is the calculation of spontaneous emission rates from a given magnetic sublevel. This involves a sum over the final states contributions. Summing over the magnetic sublevels of the p level we find

$$\mathcal{A}^2_{s\to p} \equiv \sum_{m=-1}^{1} \mathcal{A}^2_{00,1m} = 1. \tag{2.99}$$

Using this sum rule we obtain for the total transition probability

$$D^2_{3s,2p} = e^2 a^2 \mathcal{R}^2_{3s,2p} \sum_{m=-1}^{1} \mathcal{A}^2_{00,1m} = 0.880\,60\, e^2 a^2/Z^2. \tag{2.100}$$

$nd \leftrightarrow 2p$ transitions
Substituting the expressions for $\tilde{R}_{2p}(\rho)$ and $\tilde{R}_{nd}(\rho)$ from Eq. (2.37) into the radial integral (2.62) and changing to the variable $x = 2Z\rho/n$ the radial integral becomes

$$\mathcal{R}_{nd,2p} \equiv (1/Z)\frac{1}{32\sqrt{6}}\sqrt{\frac{(n-3)!}{(n+2)!}}\,n^3 \int x^6 e^{-(n+2)x/4} L^5_{n-3}(x)dx. \tag{2.101}$$

The integral is evaluated by repetitive use (5×) of the recursion relation (L.80a)

$$\int x^6 e^{-(n+2)x/4} L^5_{n-3}(x)dx = \sum_{n'=0}^{n-3} \sum_{n''=0}^{n'} \sum_{n'''=0}^{n''} \sum_{n''''=0}^{n'''} \sum_{k=0}^{n''''} \int x^6 e^{-(n+2)x/4} L_k(x)dx. \tag{2.102}$$

Evaluating the integral and summation we obtain

$$\mathcal{R}_{nd,2p} = (1/Z)2^9\sqrt{2/3}\,n^5(n^2-1)\frac{(n-2)^{n-3}}{(n+2)^{n+3}}\sqrt{\frac{(n-3)!}{(n+2)!}} \qquad n > 2. \tag{2.103}$$

The angular integral yields for $d \leftrightarrow p$ transitions

$$\mathcal{A}_{2m',10} = (-1)^{-m'}\sqrt{2}\begin{pmatrix} 1 & 1 & 2 \\ 0 & m' & -m' \end{pmatrix} = (-1)^{-m'}\sqrt{\frac{4-m'^2}{15}}, \tag{2.104a}$$

$$\mathcal{A}_{2m',1\pm1} = (-1)^{-m'}\sqrt{2}\begin{pmatrix} 1 & 1 & 2 \\ \pm1 & m'\mp1 & m' \end{pmatrix} = (-1)^{-m'}\begin{cases} \sqrt{\frac{2+3m'+m'^2}{30}} & 0 \le m' \le 2 \\ \sqrt{\frac{2-3m'+m'^2}{30}} & -2 \le m' \le 0. \end{cases} \tag{2.104b}$$

For the case $n = 3$ we find for the $3d_{m'} \leftrightarrow 2p_m$ Balmer-α transition strengths - see Problem 2.6

$$D^2_{3dm',2pm} = e^2 a^2 \mathcal{R}^2_{3d,2p} \mathcal{A}^2_{2m',1m} = 22.543\,\mathcal{A}^2_{2m',1m} e^2 a^2/Z^2. \tag{2.105}$$

Summing over the magnetic quantum numbers of the p or d level we obtain the sum rules

$$\sum_{m=-1}^{1} \mathcal{A}^2_{2m',1m} = \sum_{m=-2}^{2} \mathcal{A}^2_{2m,1m'} = \tfrac{2}{5}. \tag{2.106}$$

Interestingly, this sum is *independent* of the choice of the initial magnetic sublevel m' as is illustrated in Fig. 2.5. We return to the use of sum rules when discussing electric-dipole transitions in the presence of fine structure (Section 4.6.4) and hyperfine structure (Section 5.3.7). For the case $n = 3$ we find for the $3d_m \to 2p$ and $2p_m \to 3d$ Balmer-α transition probabilities

$$D^2_{3d_m,2p} = D^2_{3d,2p_m} = 9.0172\, e^2 a^2/Z^2. \tag{2.107}$$

Problem 2.6. Verify the general expressions for $1s \leftrightarrow np$, $2s \leftrightarrow np$ and $2p \leftrightarrow nd$ transitions by direct substitution of Eqs. (2.40) into Eq. (2.62) for the $1s \leftrightarrow 2p$ (*Lyman* α), the $2s \leftrightarrow 2p$ and $2p \leftrightarrow 3d$ transitions in hydrogen.

Solution. By direct substitution of Eqs. (2.40) into Eq. (2.62) we calculate

$$\begin{aligned}
\mathcal{R}_{2p,1s} &\equiv \int_0^\infty \rho^3 \tilde{R}_{2p}(\rho)\tilde{R}_{1s}(\rho)d\rho = +1.29027/Z \\
\mathcal{R}_{2p,2s} &\equiv \int_0^\infty \rho^3 \tilde{R}_{2p}(\rho)\tilde{R}_{2s}(\rho)d\rho = -5.19616/Z \\
\mathcal{R}_{2p,3d} &\equiv \int_0^\infty \rho^3 \tilde{R}_{3d}(\rho)\tilde{R}_{2p}(\rho)d\rho = +4.74799/Z.
\end{aligned}$$

These values are used in the formulas for $1s \leftrightarrow np$, $2s \leftrightarrow np$ and $2p \leftrightarrow nd$ transitions. □

3

Angular Momentum

In Chapter 1 we solved the Schrödinger equation for the motion of a particle in a central potential field. Exploiting the central symmetry we found separate equations of motion as a function of r, θ and ϕ and established that the radial and angular motions are quantized. For the angular motion this was expressed by the eigenvalue equations for the operators $\mathbf{L}^2$ and L_z. In the present chapter we develop another line of reasoning. We start by demonstrating that the properties of quantized angular momentum follow directly from the commutation relations (1.29). In particular, the eigenvalues of $\mathbf{L}^2$ and L_z and the properties of L_+ and L_- are obtained *without* solving the Schrödinger equation. This leads us to generalize the discussion: whenever we meet a vector operator $\mathbf{J}$ of which the cartesian components, J_x, J_y and J_z, are hermitian operators satisfying commutation relations of the type (1.29), the quantization properties of its observables are immediately known. We shall find that these commutation rules define an algebra that not only reproduces the properties obtained in Chapter 1 but also allows for different (non-classical) kinds of angular momentum. In Section 3.2 we introduce the matrix representation for angular momentum operators in vector spaces of arbitrary dimension. For the two-dimensional case we obtain the Pauli matrices, identifying spin as a $s = \frac{1}{2}$ form of angular momentum. In Section 3.4 we introduce the vector addition of two angular momenta to form a total angular momentum. We define the coupled and the uncoupled representation and introduce the Clebsch-Gordan transformation between these two. In Section 3.8 we investigate the relation between rotations in real space and unitary transformations in Hilbert spaces. We find for the spin $s = \frac{1}{2}$ case that the angular momentum operators S_x, S_y and S_z can be written as differential operators representing infinitesimal rotations about the x, y and z axis, respectively.

In Section 3.9 we arrive at the *formal definition* of the angular momentum operator J_a as an infinitesimal rotation about the direction $\hat{\mathbf{a}}$. From this definition all properties of quantized angular momentum follow in a few steps. We find that half-integral angular momenta have rotation properties that do not exist in classical physics.

Introductions in the theory of quantized angular momentum are given by Albert Messiah [75, 76] and in dedicated books on *Angular Momentum* by Morris E. Rose [94] and A.R. Edmonds [36]. The classics by Ugo Fano and Giulio Racah on *Irreducible Tensorial Sets* [39] and by Eugene P. Wigner on *Group Theory* [122] put emphasis on the mathematical basis of the theory.

3.1 Angular momentum algebra

In this section we demonstrate that the vector operator $\mathbf{J}$ has the properties of an *angular momentum operator* if its cartesian components (J_x, J_y and J_z in some frame of reference $\mathcal{S}$) are *hermitian* operators satisfying the commutation relations

$$[J_x, J_y] = i\hbar J_z, \;\; [J_y, J_z] = i\hbar J_x \;\text{ and }\; [J_z, J_x] = i\hbar J_y. \tag{3.1}$$

Using the *inner product rule*

$$\mathbf{J}^2 = J_x^2 + J_y^2 + J_z^2, \tag{3.2}$$

it is straightforward to show that $\mathbf{J}^2$ commutes with J_z - see Eq. (1.31). Therefore, $\mathbf{J}^2$ and J_z share a complete set of eigenstates (see Problem F.1). Adopting the Dirac notation we denote this joint basis by $\{|\lambda, m\rangle\}$ and the corresponding eigenvalue equations take the form

$$\mathbf{J}^2 |\lambda, m\rangle = \lambda\hbar^2 |\lambda, m\rangle \text{ and } J_z |\lambda, m\rangle = m\hbar |\lambda, m\rangle, \tag{3.3}$$

where the eigenvalues λ and m are *real* numbers still to be determined. Note that, equally well we could have chosen the joint basis of $\mathbf{J}^2$ and J_x (or $\mathbf{J}^2$ and J_y). By selecting $\mathbf{J}^2$ and J_z we adopted the z axis of our coordinate system $\mathcal{S}$ as the *quantization axis* in the real space of observation; the basis $\{|\lambda, m\rangle\}$ that diagonalizes $\mathbf{J}^2$ and J_z simultaneously defines the *standard representation* $\{\mathbf{J}^2, J_z\}$.

Like in the case of orbital angular momentum we proceed by introducing *shift operators*

$$J_\pm \equiv J_x \pm iJ_y. \tag{3.4}$$

For convenience of reference we also give the inverse relations

$$J_x = \tfrac{1}{2}(J_+ + J_-) \quad \text{and} \quad J_y = -i\tfrac{1}{2}(J_+ - J_-). \tag{3.5}$$

Note that J_+ and J_- are *hermitian conjugates*, as follows from the hermiticity of J_x and J_y,

$$\begin{aligned} \langle\chi'| J_+ |\chi\rangle &= \langle\chi'| J_x |\chi\rangle + \langle\chi'| iJ_y |\chi\rangle \\ &= \langle\chi| J_x |\chi'\rangle^* - i \langle\chi| J_y |\chi'\rangle^* = \langle\chi| J_- |\chi'\rangle^*, \end{aligned} \tag{3.6}$$

where $|\chi\rangle$ and $|\chi'\rangle$ represent arbitrary angular momentum states. With the aid of the commutation relations (3.1) it is straightforward to derive commutation relations for the shift operators - compare Eqs. (1.36) and (1.38),

$$[J_z, J_\pm] = \pm\hbar J_\pm \text{ and } [J_+, J_-] = 2\hbar J_z. \tag{3.7}$$

Furthermore, we can derive the following operator identities - cf. Eqs. (1.37),

$$J_-J_+ = \mathbf{J}^2 - J_z^2 - \hbar J_z \tag{3.8a}$$

$$J_+J_- = \mathbf{J}^2 - J_z^2 + \hbar J_z. \tag{3.8b}$$

Adding these equations we obtain the *inner product rule*

$$\mathbf{J}^2 = J_z^2 + \tfrac{1}{2}[J_+J_- + J_-J_+]. \tag{3.9}$$

The shift operators are introduced because they enable us to construct the subspace V_λ of the angular momentum Hilbert space corresponding to the eigenvalue λ. To elucidate this point we note that J_+ is an operator that *raises* the eigenvalue $m\hbar$ by one unit of angular momentum about the quantization axis; i.e., if $|\lambda, m\rangle$ is an eigenstate of J_z with the eigenvalue $m\hbar$ also $J_+ |\lambda, m\rangle$ will be an eigenstate of J_z but with eigenvalue $(m+1)\hbar$,

$$J_zJ_+ |\lambda, m\rangle = (J_+m\hbar + \hbar J_+) |\lambda, m\rangle = (m+1)\hbar J_+ |\lambda, m\rangle. \tag{3.10}$$

This follows directly from the commutation relations (3.7). Comparing Eq. (3.10) with the generic eigenvalue relation (3.3) we find

$$J_+ |\lambda, m\rangle = c_+(\lambda, m)\, \hbar\, |\lambda, m+1\rangle, \tag{3.11}$$

where $c_+(\lambda, m)$ is a (generally complex) constant to be determined. Likewise, we find that J_- is an operator that *lowers* the eigenvalue by $\hbar$,

$$J_- |\lambda, m\rangle = c_-(\lambda, m)\, \hbar\, |\lambda, m-1\rangle. \tag{3.12}$$

Thus we established that for a given eigenvalue λ the operators $J_\pm$ act as *construction operators* by which new angular momentum eigenstates of the subspace V_λ can be generated.

We are now in a position to determine the constants $c_\pm(\lambda, m)$. As we shall see this leads us to the quantized spectrum of λ and m. First we derive a relation between c_+ and c_- using the property that J_+ and J_- are hermitian conjugates,

$$c_+(\lambda, m) \equiv \langle j, m+1| (J_+/\hbar) |j, m\rangle = \langle j, m| (J_-/\hbar) |j, m+1\rangle^* = c_-^*(\lambda, m+1)\,. \tag{3.13}$$

We proceed by deriving two expressions for the expectation value $\langle \lambda, m| J_- J_+ |\lambda, m\rangle$. Using Eqs. (3.11), (3.12) and (3.13) we obtain

$$\langle \lambda, m| J_- J_+ |\lambda, m\rangle = c_-(\lambda, m+1)\, c_+(\lambda, m)\, \hbar^2 = |c_+(\lambda, m)|^2 \hbar^2. \tag{3.14}$$

On the other hand from Eq. (3.8a) it follows that

$$\langle \lambda, m| J_- J_+ |\lambda, m\rangle = \langle \lambda, m| \mathbf{J}^2 - J_z^2 - \hbar J_z |\lambda, m\rangle = [\lambda - m(m+1)]\, \hbar^2. \tag{3.15}$$

Equating Eqs. (3.14) and (3.15) we find the condition

$$0 \le |c_+(\lambda, m)|^2 = \lambda - m(m+1). \tag{3.16}$$

Repeating the derivation starting from $J_+ J_-$ we obtain in a similar way

$$0 \le |c_-(\lambda, m)|^2 = \lambda - m(m-1). \tag{3.17}$$

To assure that the conditions (3.16) and (3.17) are not violated, the construction of the subspace V_λ by the operators $J_\pm$ has to be terminated at some point; i.e., we require the existence of a maximum and a minimum value of m, $-\bar{j} \le m \le j$. The only way in which these bounds follow logically from the algebra is if the conditions $c_+(\lambda, j) = 0$ and $c_-(\lambda, -\bar{j}) = 0$ are simultaneously satisfied. Together with Eqs. (3.16) and (3.17) this leads to the condition

$$\lambda = j(j+1) = \bar{j}(\bar{j}+1). \tag{3.18}$$

Hence, we find $\bar{j} = j$ and since m has to vary in integral steps, the condition $-j \le m \le j$ implies that j and m have to be either both *integers* $(0, 1, 2, \cdots)$ or *half-integers* $(\frac{1}{2}, \frac{3}{2}, \cdots)$. Other values of j and m are not allowed because the construction procedure would not be truncated by the algebra and result in violation of the conditions (3.16) and (3.17). For the coefficients we find the relation

$$|c_\pm(j(j+1), m)|^2 = j(j+1) - m(m \pm 1). \tag{3.19}$$

Simplifying the notation, $c_\pm(j(j+1), m) \to C_{j,\pm m}$, and choosing the phase of $C_{j,m}$ such that it always represents a *non-negative real* number we obtain the coefficients in the *Condon and Shortley phase convention* [28],

$$C_{j,m} \equiv \sqrt{j(j+1) - m(m+1)} = \sqrt{(j-m)\,(j+m+1)}. \tag{3.20}$$

This convention represents a generalization of the phase convention introduced in Section 1.1.6.1 to the case of arbitrary angular momenta. In view of Eqs. (3.11) and (3.12) this convention assures that the basis states $\{|j, m\rangle\}$ are constructed with the same relative phase.

3.1.0.1 Summary:

A vector operator $\mathbf{J}$ is called *angular momentum operator* if its cartesian components (J_x, J_y and J_z in some frame of reference $\mathcal{S}$) are *hermitian* operators satisfying the following commutation relations

$$[J_i, J_j] = i\hbar\varepsilon_{ijk}J_k, \tag{3.21}$$

with $i, j, k \in \{x, y, z\}$. Choosing the quantization axis along the z direction of a cartesian coordinate system in the euclidean space of observation, the eigenvalue equations of an arbitrary angular momentum operator $\mathbf{J}$ can be written in the form,

$$\mathbf{J}^2 |j, m\rangle = j(j+1)\hbar^2 |j, m\rangle \tag{3.22a}$$

$$J_z |j, m\rangle = m\hbar |j, m\rangle . \tag{3.22b}$$

The quantum numbers j and m are called *rotational quantum numbers.* They are either both integral or half-integral. The quantum number m is often referred to as the *magnetic quantum number* and is restricted to the interval

$$-j \leq m \leq j. \tag{3.23}$$

The kets $|j, m\rangle$ correspond to the basis vectors in the *standard representation* $\{\mathbf{J}^2, J_z\}$ of a $d = 2j+1$ dimensional subspace V^d of Hilbert space, with $d = 1, 2, 3, \cdots$. Using the Condon and Shortley phase convention the shift relations (3.11) and (3.12) become

$$J_\pm |j, m\rangle = C_{j,\pm m}\hbar |j, m \pm 1\rangle \tag{3.24a}$$

where the *shift coefficients* $C_{j,\pm m}$ are *non-negative* and *real*,

$$C_{j,\pm m} \equiv \sqrt{j(j+1) - m(m \pm 1)}, \tag{3.24b}$$

with the *symmetry properties*

$$C_{j,\pm m} = C_{j,\mp m-1}. \tag{3.24c}$$

In this convention all sublevels $|j, m\rangle$ can be constructed from $|j, j\rangle$ by repeated action of the lowering operator,

$$|j, m\rangle = \sqrt{\frac{(j+m)!}{(2j)!\,(j-m)!}} \left(\frac{J_-}{\hbar}\right)^{j-m} |j, j\rangle . \tag{3.24d}$$

This expression is readily verified by induction. Note that the shift operators conserve the phase. Therefore, for *given* j, all $|j, m\rangle$ carry the *same phase.* Furthermore, the shift operators satisfy the following commutation relations:

$$[J_\pm, J_\pm] = 0, \quad [J_\pm, J_\mp] = \pm 2\hbar J_z, \quad [J_z, J_\pm] = \pm\hbar J_\pm. \tag{3.25}$$

3.1.1 Shift operators versus standard components of vector operators

With respect to the *cartesian basis* the angular momentum operator $\mathbf{J}$ can be written as

$$\mathbf{J} = \hat{\mathbf{x}}J_x + \hat{\mathbf{y}}J_y + \hat{\mathbf{z}}J_z, \tag{3.26}$$

where J_x, J_y, J_z are the cartesian components. An inconvenience of the cartesian decomposition is that the properties of the angular momentum are best accessed by the operators J_z, J_+ and J_-. Thus we are lead to re-express J_x and J_y in terms of the shift operators. Substituting Eqs. (3.5) into (3.26) we find

$$\mathbf{J} = \tfrac{1}{2}(\hat{\mathbf{x}} - i\hat{\mathbf{y}})\,J_+ + \tfrac{1}{2}(\hat{\mathbf{x}} + i\hat{\mathbf{y}})\,J_- + \hat{\mathbf{z}}J_z. \tag{3.27}$$

Here we recognize the *spherical* unit vectors (2.66),

$$\mathbf{J} = -\sqrt{\tfrac{1}{2}}\hat{\mathbf{u}}_{+1}^{*}J_{+} + \hat{\mathbf{u}}_{0}^{*}J_{z} + \sqrt{\tfrac{1}{2}}\hat{\mathbf{u}}_{-1}^{*}J_{-}. \tag{3.28}$$

Rewriting this expression in the form

$$\mathbf{J} = \hat{\mathbf{u}}_{+1}^{*}J_{+1} + \hat{\mathbf{u}}_{0}^{*}J_{0} + \hat{\mathbf{u}}_{-1}^{*}J_{-1} \tag{3.29}$$

we obtain the *standard decomposition* of **J**. The *standard components* J_{+1}, J_0, J_{-1} are defined by[1]

$$J_0 = J_z; \qquad J_{\pm1} = \mp\sqrt{\tfrac{1}{2}}(J_x \pm iJ_y) = \mp\sqrt{\tfrac{1}{2}}J_{\pm}. \tag{3.30}$$

As the decomposition of **J** maps onto that of the radius vector **r**, see Eq. (2.65), the standard components have the same transformation properties as the $Y_1^m(\hat{\mathbf{r}})$. This implies that, with the standard decomposition we adopt the *Condon and Shortley* phase convention. Operators that transform like the $Y_l^m(\hat{\mathbf{r}})$ are called *spherical tensor* operators [93]. For $l = 1$ the tensor operator is called *vector* operator, for $l = 0$ *scalar* operator. The standard decomposition can be applied to any vector operator and is used in unified approaches for the calculation of matrix elements in systems with angular momentum (see Appendix K). We return to the transformation properties of **J** in Section 3.8.

3.2 Matrix representation of angular momentum

The dimension of a $d = 2j + 1$ dimensional subspace V^d becomes most explicit in the matrix notation, where an arbitrary state of angular momentum is represented by a normalized column vector of dimension d and the angular momentum operators by $d \times d$ matrices. In the case of *orbital* angular momentum this dimension is an *odd* integer because the quantum number j is an integer. In general, the dimension of the vector space can be *odd* (integral angular momentum) or *even* (half-integral angular momentum). In the present section we shall determine some of these matrices starting from the eigenvalue equations (3.22). In Section 3.9 they will be rederived using a formal generating procedure.

3.2.1 Example: the case $l = 1$ - spherical basis

First we discuss an example of integral angular momentum. We shall use the *spherical* basis $\{|l, m_l\rangle\}$, well known from the eigenstates of orbital angular momentum. In the matrix representation the states are represented by column vectors of *odd* dimension $d = 2l + 1$. The example is given for the case $l = 1$ where the basis vectors correspond to $m_l \in \{-1, 0, 1\}$ and are given by

$$|1,1\rangle = \begin{pmatrix}1\\0\\0\end{pmatrix}, \quad |1,0\rangle = \begin{pmatrix}0\\1\\0\end{pmatrix}, \quad |1,-1\rangle = \begin{pmatrix}0\\0\\1\end{pmatrix}. \tag{3.31}$$

The angular momentum operators L_a, with $a \in \{\pm, z\}$, are represented by 3×3 matrices of elements $\langle l', m_l'|L_a|l, m_l\rangle$, which can be determined with the aid of Eqs. (3.22b) and (3.24). Using Eq. (3.22b) we find for the L_z operator

$$L_z = \hbar\begin{pmatrix}1 & 0 & 0\\0 & 0 & 0\\0 & 0 & -1\end{pmatrix}. \tag{3.32}$$

---

[1] Beware of the subtle difference between $J_{\pm1}$ and $J_{\pm}$

As the L_z operator is diagonal in this representation, the spherical representation is called the *diagonal representation.* Using the same approach we find with Eqs. (3.24) for the shift operators

$$L_+ = \sqrt{2}\,\hbar \begin{pmatrix} 0 & 1 & 0 \\ 0 & 0 & 1 \\ 0 & 0 & 0 \end{pmatrix}, \quad L_- = \sqrt{2}\,\hbar \begin{pmatrix} 0 & 0 & 0 \\ 1 & 0 & 0 \\ 0 & 1 & 0 \end{pmatrix}. \tag{3.33}$$

The expressions for L_x and L_y follow from the definitions of the shift operators,

$$L_x = \frac{\hbar}{\sqrt{2}} \begin{pmatrix} 0 & 1 & 0 \\ 1 & 0 & 1 \\ 0 & 1 & 0 \end{pmatrix}, \quad L_y = \frac{\hbar}{\sqrt{2}} \begin{pmatrix} 0 & -i & 0 \\ i & 0 & -i \\ 0 & i & 0 \end{pmatrix}. \tag{3.34}$$

It is readily verified that these 3×3 matrices indeed satisfy the commutation relations (3.1), (1.36) and (1.38). Note that the operators L_u are *traceless*, $\operatorname{tr} L_u = 0$, with $u \in \{x, y, z\}$, where the trace of the matrix is defined by Eq. (M.5). Furthermore, it is straightforward to show with Eq. (1.39) that $\mathbf{L}^2 = 2\hbar^2 \mathbb{1}$, where $\mathbb{1}$ is the unit matrix. Hence, also Eq. (1.57a) is satisfied; note that $\mathbf{L}^2$ and L_z are both diagonal.

3.2.2 Example: the case $l = 1$ - cartesian basis

Of course we are free to choose any set of three orthogonal unit vectors to span the $l = 1$ angular momentum Hilbert space. For the case $l = 1$ the *cartesian* basis deserves our attention,[1]

$$|x\rangle = \begin{pmatrix} 1 \\ 0 \\ 0 \end{pmatrix}, \quad |y\rangle = \begin{pmatrix} 0 \\ 1 \\ 0 \end{pmatrix}, \quad |z\rangle = \begin{pmatrix} 0 \\ 0 \\ 1 \end{pmatrix}.$$

This basis is obtained from spherical basis by the same unitary transformation as the one that separates the spherical harmonic $Y_1^m(\hat{\mathbf{r}})$ into its real and imaginary part - see also Eq. (L.55)

$$|x\rangle \equiv -\frac{1}{\sqrt{2}}(|1,1\rangle - |1,-1\rangle), \qquad |y\rangle \equiv \frac{i}{\sqrt{2}}(|1,1\rangle + |1,-1\rangle), \qquad |z\rangle \equiv |1,0\rangle. \tag{3.35}$$

Note that these vectors are normalized and orthogonal. The angular momentum operators L_a, with $a \in \{\pm, z\}$, are represented by 3×3 matrices of elements $\langle u'|L_a|u\rangle$, with $u, u' \in \{|x\rangle, |y\rangle, |z\rangle\}$. Using Eq. (3.22b) we find for the L_z operator:

$$L_z|x\rangle = i|y\rangle, \quad L_z|y\rangle = -i|x\rangle, \quad L_z|z\rangle = 0. \tag{3.36}$$

Having these relations it is straightforward to determine L_z operator in the cartesian representation

$$L_z = \hbar \begin{pmatrix} 0 & -i & 0 \\ i & 0 & 0 \\ 0 & 0 & 0 \end{pmatrix}. \tag{3.37}$$

Note that the representation is no longer diagonal. Likewise, using Eqs. (3.24) we find the following properties for the shift operators

$$L_+|x\rangle = +|z\rangle, \quad L_+|y\rangle = i|z\rangle, \quad L_+|z\rangle = \sqrt{2}|1,1\rangle = -|x\rangle - i|y\rangle \tag{3.38a}$$

$$L_-|x\rangle = -|z\rangle, \quad L_-|y\rangle = i|z\rangle, \quad L_-|z\rangle = \sqrt{2}|1,1\rangle = +|x\rangle - i|y\rangle. \tag{3.38b}$$

---

[1] Beware that these three unit vectors represent a basis of Hilbert space and *have nothing to do* with the cartesian basis of the real space (e.g. the laboratory-fixed frame) in which the angular momentum is observed.

From these relations we find for the shift operators in the cartesian representation

$$L_+ = \hbar \begin{pmatrix} 0 & 0 & -1 \\ 0 & 0 & -i \\ 1 & i & 0 \end{pmatrix}, \quad L_- = \hbar \begin{pmatrix} 0 & 0 & 1 \\ 0 & 0 & -i \\ -1 & i & 0 \end{pmatrix}. \tag{3.39}$$

Using the definitions of the shift operators we obtain the matrix representations of L_x and L_y,

$$L_x = \hbar \begin{pmatrix} 0 & 0 & 0 \\ 0 & 0 & -i \\ 0 & i & 0 \end{pmatrix}, \quad L_y = \hbar \begin{pmatrix} 0 & 0 & i \\ 0 & 0 & 0 \\ -i & 0 & 0 \end{pmatrix}. \tag{3.40}$$

It is readily verified that these 3×3 matrices indeed satisfy the commutation relations (3.1), (1.36) and (1.38). Furthermore, using Eq. (1.32) it is straightforward to demonstrate the operator identity $\mathbf{L}^2 = 2\hbar^2\mathbb{1}$. Hence, also Eq. (1.57a) is satisfied. Note that the matrices L_u are again *traceless*, $\operatorname{tr} L_u = 0$, with $u \in \{x, y, z\}$, as they should be because the trace of a matrix is invariant under unitary transformation.

3.2.3 Example: the case $s = 1/2$ - Pauli spin matrices

For the case of half-integral angular momentum we shall use (in this example) the notation $|s, m_s\rangle$. In the matrix representation the states are represented by column vectors of *even* dimension $d = 2s+1$. In particular, for the case $s = \frac{1}{2}$ the basis vectors correspond to $m_s \in \{-\frac{1}{2}, \frac{1}{2}\}$. We shall meet this case when discussing the intrinsic angular momentum of the electron, the electron spin $\mathbf{S}$. It is good to emphasize already at this point that the case $s = \frac{1}{2}$ is of more general importance because it can be used to describe any quantum mechanical two-level system. The basis vectors are [1]

$$|+\rangle = |\uparrow\rangle \equiv |\tfrac{1}{2}, \tfrac{1}{2}\rangle = \begin{pmatrix} 1 \\ 0 \end{pmatrix}, \quad |-\rangle = |\downarrow\rangle \equiv |\tfrac{1}{2}, -\tfrac{1}{2}\rangle = \begin{pmatrix} 0 \\ 1 \end{pmatrix}. \tag{3.41}$$

The operators S_+, S_- and S_z are given by 2×2 matrices, which are easy to determine using Eqs. (3.22b) and (3.24) in accordance with the phase convention (3.20)

$$S_z = \hbar \begin{pmatrix} 1/2 & 0 \\ 0 & -1/2 \end{pmatrix}, \quad S_+ = \hbar \begin{pmatrix} 0 & 1 \\ 0 & 0 \end{pmatrix}, \quad S_- = \hbar \begin{pmatrix} 0 & 0 \\ 1 & 0 \end{pmatrix}. \tag{3.42}$$

Defining

$$\mathbf{S} = \tfrac{1}{2}\hbar\boldsymbol{\sigma}, \tag{3.43}$$

the corresponding matrices for the cartesian components of $\boldsymbol{\sigma}$ are given by

$$\sigma_x = \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}, \quad \sigma_y = \begin{pmatrix} 0 & -i \\ i & 0 \end{pmatrix}, \quad \sigma_z = \begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix}. \tag{3.44}$$

These matrices are called the *Pauli spin matrices.* They are *traceless*, $\operatorname{tr} \sigma_u = 0$, *idempotent*, $\sigma_u^2 = \mathbb{1}$, have *negative determinant*, $\det \sigma_u = -1$, and satisfy the relation

$$\sigma_u \sigma_v = \mathbb{1}\,\delta_{uv} + i\varepsilon_{uvw}\sigma_w, \text{ with } u, v, w \in \{x, y, z)\}. \tag{3.45}$$

This combination is unique for $s = \frac{1}{2}$. We can also decompose the Pauli matrix $\boldsymbol{\sigma}$ along a quantization axis in the arbitrary direction $\hat{\mathbf{r}} = (\theta, \phi) = (x, y, z)$,

$$\sigma_r \equiv \hat{\mathbf{r}} \cdot \boldsymbol{\sigma} = x\sigma_x + y\sigma_y + z\sigma_z, \tag{3.46}$$

---

[1] In quantum information science one uses the notation $|0\rangle \equiv |\uparrow\rangle$ and $|1\rangle \equiv |\downarrow\rangle$ for the basis vectors that define the possible superposition states of the *qubit.*

where $x = \sin\theta\cos\phi$, $y = \sin\theta\sin\phi$ and $z = \cos\theta$ are the cartesian components of the unit vector $\hat{\mathbf{r}}$, cf. Eq. (1.13a). The operator σ_r is said to measure the angular momentum of the $s = \frac{1}{2}$ system in the direction $\hat{\mathbf{r}}$. Note that with the substitution $\hat{\mathbf{r}} \to \hat{\mathbf{z}}$ we have $x = y = 0$ and $z = 1$, regaining σ_z as we should. In terms of the spherical components σ_+, σ_- and σ_z the component σ_r can be written in the form

$$\sigma_r = \tfrac{1}{2}(x - iy)\sigma_+ + \tfrac{1}{2}(x + iy)\sigma_- + z\sigma_z. \tag{3.47}$$

In matrix notation σ_r becomes

$$\sigma_r = \begin{pmatrix} z & x - iy \\ x + iy & -z \end{pmatrix} = \begin{pmatrix} \cos\theta & \sin\theta\, e^{-i\phi} \\ \sin\theta\, e^{i\phi} & -\cos\theta \end{pmatrix}, \tag{3.48}$$

as follows immediately by substitution of the Pauli matrices into Eq. (3.46). Note that

$$\sigma_r^2 = \mathbb{1}. \tag{3.49}$$

This does not come as a surprise because by choosing the quantization axis along the direction $\hat{\mathbf{r}}$ we have $\sigma_r \to \sigma_z$ and Eq. (3.45). A valuable operator identity is (see Problem 3.1)

$$(\boldsymbol{\sigma} \cdot \mathbf{A})(\boldsymbol{\sigma} \cdot \mathbf{B}) = \mathbf{A} \cdot \mathbf{B} + i\, \boldsymbol{\sigma} \cdot (\mathbf{A} \times \mathbf{B}), \tag{3.50}$$

where $\mathbf{A}$ and $\mathbf{B}$ are vector operators that commute with $\boldsymbol{\sigma}$.

Problem 3.1. Prove the relation (3.50)

Solution. Since $\mathbf{A}$ and $\mathbf{B}$ commute with $\boldsymbol{\sigma}$ we have in Einstein notation

$$(\boldsymbol{\sigma} \cdot \mathbf{A})(\boldsymbol{\sigma} \cdot \mathbf{B}) = \sigma_u \sigma_v A_u B_v.$$

Using the property (3.45) this becomes

$$(\boldsymbol{\sigma} \cdot \mathbf{A})(\boldsymbol{\sigma} \cdot \mathbf{B}) = \mathbb{1}\delta_{uv} A_u B_v + i\sigma_w \varepsilon_{uvw} A_u B_v = \mathbb{1} A_u B_u + i\sigma_w \left(\mathbf{A} \times \mathbf{B}\right)_w,$$

which can be rewritten in the desired form. □

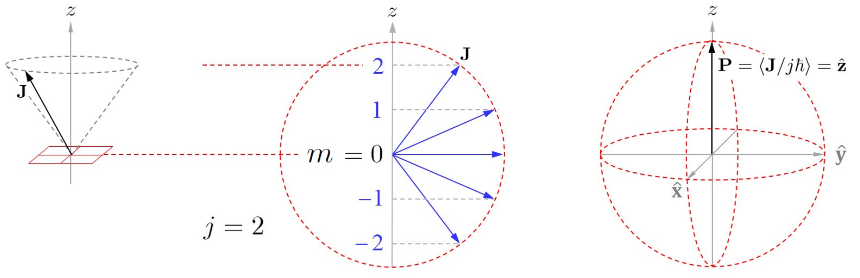
3.3 Vector model and polarization

In this section we elaborate on the measurement of angular momentum. We already established that the angular momentum of a physical system is a vector quantity, which, in a cartesian frame of reference, can be written in the form

$$\mathbf{J} = \hat{\mathbf{x}} J_x + \hat{\mathbf{y}} J_y + \hat{\mathbf{z}} J_z. \tag{3.51}$$

In classical physics the state of angular momentum can be determined to arbitrary precision by measuring the magnitude, direction and sense of the vector $\mathbf{J}$. For closed mechanical systems this quantity is conserved in time (cf. Appendix D.5.4). In quantum mechanics, the best we can do is prepare the system in an eigenstate, $|j, m\rangle$, where j defines the magnitude and m the projection (including sense) of the angular momentum with respect to the quantization axis. The *direction* remains undetermined in this process. Formally, it makes no sense to ask for the direction because the components of $\mathbf{J}$ do not commute. This makes J_x, J_y and J_z into *incompatible* operators, which means that (by lack of a common basis) the components of the vector *operator* $\mathbf{J}$ cannot be determined simultaneously to arbitrary precision (cf. Appendix F.1.1).

A way to visualize the difference between angular momentum in classical physics and in quantum mechanics is the semi-classical *vector model* illustrated in Fig. 3.1*a*. In this model, the angular momentum is represented by a *semi-classical vector* of *quantized magnitude*, $\sqrt{\langle \mathbf{J}^2 \rangle} = \sqrt{j(j+1)}\hbar$, and *quantized projection* on the z axis, $\langle J_z \rangle = m\hbar$. Importantly, the same projection is obtained for



(b) (a) (c)

Figure 3.1: (a) Vector model for a system with angular momentum $\mathbf{J}$ for the case $j = 2$; (b) Preparing the system in the state $|2, 2\rangle$ the direction of the vector $\mathbf{J}$ is restricted to a cone of possible values, all sharing the same *quantized* projection onto the z axis. The quantum numbers j and m are conserved - the direction on the cone is uncertain. (c) The polarization of the state $|2, 2\rangle$ is given by $\mathbf{P} = \langle \mathbf{J}/j\hbar \rangle = \hat{\mathbf{z}}$.

all vectors on the cone of possibilities shown in Fig. 3.1*b*. This indicates that, whereas any vector on the cone corresponds to a *classically* distinguishable state, quantum mechanically the direction on the cone is undetermined (all directions are equally probable). One may argue that it makes little sense to draw a vector for a direction that cannot be determined. However, as we shall see later, the *operator* $\mathbf{J}$ transforms under rotation exactly like the classical angular momentum vector. Although the direction itself has no observable meaning, changes in the direction (e.g., caused by *precession* of $\mathbf{J}$ about the quantization axis) can be (and have been) observed experimentally (cf. Section 3.9.2). Moreover, we shall find that also the addition of angular momentum operators proceeds as in the case of classical vectors (under the constraint of quantization - see Section 3.4.2). All this being said, vector diagrams offer a valuable geometric tool for visualizing the addition and rotation of angular momenta under the constraint of quantization.

In a typical (state-selective) measurement, the state in which a system is prepared is destroyed by projection on the state of observation. So, to gain more information about the state of a system, the best we can do with a state-selective detector (a detector that discriminates between the eigenstates) is repeat the measurement with identically prepared systems until the desired precision is reached. In this way we can determine the expectation values $\langle J_x \rangle$, $\langle J_y \rangle$ and $\langle J_z \rangle$, which define the components of the *polarization vector* of the angular momentum state prepared,

$$\mathbf{P} = \langle \mathbf{J}/j\hbar \rangle \equiv (\langle J_x/j\hbar \rangle, \langle J_y/j\hbar \rangle, \langle J_z/j\hbar \rangle)\,. \tag{3.52}$$

If the operators J_x, J_y and J_z commute with the Hamiltonian of the system the polarization is conserved in time (cf. Appendix F.2).

Let us have a look at a few examples. For particles prepared in the state $|2, 2\rangle$ with respect to the quantization axis $\hat{\mathbf{z}}$, we calculate $\mathbf{P} = (0, 0, 1) = \hat{\mathbf{z}}$ and the particles are said to be *fully polarized* in the z direction (see Fig. 3.1*c*). When prepared in the state $|2, 1\rangle$ we find $\mathbf{P} = (0, 0, \frac{1}{2}) = \frac{1}{2}\hat{\mathbf{z}}$; i.e., the particles are *partially polarized* in the z direction. For the state $|2, 0\rangle$ we calculate $\mathbf{P} = (0, 0, 0) = 0$. In this case the particles are called *unpolarized.*

Problem 3.2. Calculate for the angular momentum state $|j, m\rangle$ the following quantities:

$$\langle J_x^2 \rangle,\ \langle J_y^2 \rangle,\ \langle J_z^2 \rangle,\ \langle J_x \rangle,\ \langle J_y \rangle \text{ and } \langle J_z \rangle.$$

Discuss the relation $\langle J_x^2 \rangle + \langle J_z^2 \rangle = \langle \mathbf{J}^2 \rangle$ in the context of the semi-classical vector model.

3.3.1 Ensemble average and density matrix

Next we have a closer look at the measurement of the polarization vector. Typically one creates a beam of particles, for the above example all prepared in the state $|\psi\rangle = |2, 2\rangle$. Ideally, the particles are prepared one by one and observed sequentially using a detector that discriminates between the eigenstates $\{|j,m\rangle\}$ with respect to the quantization axis $\hat{\mathbf{z}}$. To determine $\langle J_z/j\hbar\rangle$ we measure the *probability density* to observe the particle in the eigenstate $|j,m\rangle$,

$$\mathcal{P}_m = |\langle j,m|\psi\rangle|^2, \tag{3.53}$$

subject to the Parseval relation

$$\sum_m \mathcal{P}_m = 1. \tag{3.54}$$

This type of measurement is called a *state-selective measurement* (or *filtration*). Repeating the measurement many times we find the polarization from the *ensemble average*, which is the *statistical average* over a lot of quantum measurements,

$$\mathbf{P} = \langle\!\langle \mathbf{J}/j\hbar\rangle\!\rangle \equiv (\langle\!\langle J_x/j\hbar\rangle\!\rangle, \langle\!\langle J_y/j\hbar\rangle\!\rangle, \langle\!\langle J_z/j\hbar\rangle\!\rangle)\,. \tag{3.55}$$

If all particles are prepared in the same state (as in the above example) we speak of a *pure ensemble.* Pure ensembles satisfy the property $\langle\!\langle \mathbf{J}/j\hbar\rangle\!\rangle = \langle \mathbf{J}/j\hbar\rangle$. The magnitude of the polarization vector is called the *degree of polarization*,

$$p = \sqrt{\langle\!\langle J_x/j\hbar\rangle\!\rangle^2 + \langle\!\langle J_y/j\hbar\rangle\!\rangle^2 + \langle\!\langle J_z/j\hbar\rangle\!\rangle^2}. \tag{3.56}$$

This degree can vary between zero and unity, $0 \leq p \leq 1$. For a pure ensemble prepared in the state $|\psi\rangle = |2,q\rangle$ the detector will only measure particles in the channel $|2,q\rangle$; i.e., $\mathcal{P}_m = \delta_{m,q}$, which implies $\langle\!\langle J_z/j\hbar\rangle\!\rangle = q/2$ and $\langle\!\langle J_x/j\hbar\rangle\!\rangle = \langle\!\langle J_y/j\hbar\rangle\!\rangle = 0$, and confirms the values obtained in the examples given above. The degree of polarization is $p = q/2$.

More generally one can create beams with a mixture of particles in various angular momentum states. In this case we speak of a *mixed ensemble.* The mixture may contain a bias towards certain states or be completely random. The state may vary from particle to particle but (for a given mixture) the statistical average remains well defined. For *random ensembles* all states are equally probable, which implies $\langle\!\langle J_x/j\hbar\rangle\!\rangle = \langle\!\langle J_y/j\hbar\rangle\!\rangle = \langle\!\langle J_z/j\hbar\rangle\!\rangle = 0$, whatever the quantization axis. In this case the degree of polarization is zero, $p = 0$, and the beam is called *unpolarized.*

Density matrix and statistical operator

The density matrix formalism provides an alternative method for calculating the polarization of angular momentum systems (cf. Appendix F.3). For a pure ensemble of particles prepared in the state $|\psi\rangle$ the *probability density* for observing a particle in the eigenstate $|j,m\rangle$ is given by

$$\mathcal{P}_m = |\langle j,m|\psi\rangle|^2 = \langle\rho_m\rangle, \tag{3.57}$$

where $\rho_m = |j,m\rangle\langle j,m|$ is the density operator subject to the closure relation $\mathbb{1} = \sum_m \rho_m$ and Parseval relation (cf. Appendix F.3),

$$\operatorname{tr}\rho = 1. \tag{3.58}$$

For the eigenstate $|\psi\rangle = |j,j\rangle$ the expectation value $\langle J_z\rangle$ is given by

$$\langle J_z\rangle = \operatorname{tr}\rho J_z = \sum_m \langle\psi|j,m\rangle\langle jm|J_z|\psi\rangle = j\hbar.$$

When dealing with a mixed ensemble of angular momentum eigenstates, the density operator is replaced by the *statistical operator* of the ensemble $\{|j,m\rangle\}$

$$\varrho = \sum_m w_m \rho_m, \tag{3.59}$$

where w_m is the statistical weight of the state $|j,m\rangle$ from the ensemble. Without active preparation of a specific state the ensemble is random and w_m has the same value for all m in the interval $-j < m < j$. For ensemble averages the Parseval relation relation is replaced by the trace over the statistical operator,

$$\operatorname{tr}\varrho = 1. \tag{3.60}$$

For a random ensemble of angular momentum states the degree of polarization is zero, $p = 0$ (see Problem 3.3).

Problem 3.3. Show that for a random ensemble of angular momentum states the degree of polarization is zero, $p = 0$.

Solution. Consider a random ensemble of angular momentum states. Since the ensemble is random, the probability to observe the system in the state $|j,m\rangle$ is the same for any quantization axis and for all values of m, $w_m = 1/(2j+1)$. Then, the degree of polarization is zero because the ensemble average of J_z vanishes for any quantization axis,

$$\langle\langle J_z\rangle\rangle = \operatorname{tr}\varrho J_z = w_m \sum_{m,q} \langle j,q|j,m\rangle\langle jm|J_z|j,q\rangle = w_m \sum_m m = 0. \qquad \square$$

3.3.2 The case $s = 1/2$ as a two-level system - relation with the Bloch sphere

It is appropriate to pay special attention to polarization in $s = \frac{1}{2}$ systems, the most prominent among the angular momentum systems. The $s = \frac{1}{2}$ system is a two-level systems, the simplest type of discrete quantum system. Many properties of these systems are derived in Appendix G. An arbitrary state $|\chi\rangle$ of a two-level system is determined by four parameters, three of which correspond to observable quantities. Denoting these by θ, ϕ and normalization $\mathcal{N} = 1$ the state $|\chi\rangle$ can be written in the form - see Appendix G.2.2

$$|\chi\rangle = \cos(\theta/2)\,|\uparrow\rangle + e^{i\phi}\sin(\theta/2)\,|\downarrow\rangle\,, \tag{3.61}$$

where the probablity amplitudes to observe the system in the eigenstates $|\uparrow\rangle$ and $|\downarrow\rangle$ are given by

$$a_1 = \langle\uparrow|\,\chi\rangle = \cos(\theta/2) \quad \text{and} \quad a_2 = \langle\downarrow|\,\chi\rangle = e^{i\phi}\sin(\theta/2). \tag{3.62}$$

Here ϕ represents the relative phase of the two eigenstates. Furthermore, the amplitude of the spin-up state is chosen to be real in the convention of Appendix G.2.2. The angles θ and ϕ correspond to the polar and azimuthal angles of the polarization vector $\mathbf{P}$, as follows by calculating the cartesian components of its components, $P_i = \langle 2S_i/\hbar\rangle = \langle\sigma_i\rangle$ with $i \in \{x,y,z\}$,

$$P_x = \langle\sigma_x\rangle = \tfrac{1}{2}\langle\chi|\sigma_- + \sigma_+|\chi\rangle = a_1a_2^* + a_1^*a_2 = \sin\theta\cos\phi \tag{3.63a}$$

$$P_y = \langle\sigma_y\rangle = i\tfrac{1}{2}\langle\chi|\sigma_- - \sigma_+|\chi\rangle = i(a_1a_2^* - a_1^*a_2) = \sin\theta\sin\phi \tag{3.63b}$$

$$P_z = \langle\sigma_z\rangle = \langle\chi|\sigma_z|\chi\rangle = a_1a_1^* - a_2a_2^* = \cos\theta. \tag{3.63c}$$

The polarization vector $\mathbf{P}$ is a real three-dimensional vector pointing to a point on the surface of the *Bloch sphere* - see Fig. G.1. In this context and $\mathbf{P}$ is called the *Bloch vector* of the $s = \frac{1}{2}$ system. Each point on the surface of the sphere corresponds to one of the spin states described by Eq. (3.61).

3.3.3 Two level system $(s = 1/2)$ in the density matrix formalism

Let us start with the pure state $|\chi\rangle$ defined by Eq. (3.61). This state can be used to represent an arbitrary state of a two-level system. The density operator for $|\chi\rangle$ is given by the 2×2 matrix

$$\rho = |\chi\rangle\langle\chi| = \frac{1}{2}\begin{pmatrix} 1+\cos\theta & \sin\theta\, e^{-i\phi} \\ \sin\theta\, e^{i\phi} & 1-\cos\theta \end{pmatrix}. \tag{3.64}$$

Note that $\langle\chi|\rho|\chi\rangle = 1$. This reflects the normalization of the state. It is evident that this matrix can be separated into a unit matrix and a traceless part,

$$\rho = |\chi\rangle\langle\chi| = \frac{1}{2}\left[\begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix} + \begin{pmatrix} +\cos\theta & \sin\theta\, e^{-i\phi} \\ \sin\theta\, e^{i\phi} & -\cos\theta \end{pmatrix}\right]. \tag{3.65}$$

Recalling Eq. (3.48) we find that the density operator can be written in the compact form

$$\rho = \tfrac{1}{2}\left(\mathbb{1} + \hat{\mathbf{r}} \cdot \boldsymbol{\sigma}\right). \tag{3.66}$$

Using the vector relation (3.50) we find

$$\rho^2 = \rho. \tag{3.67}$$

This *idempotence* of the density operator is a property of pure states (see Appendix F.3). The components of the polarization vector are given by the trace

$$\langle P_i\rangle = \mathrm{tr}\,(\rho\sigma_i) = \langle\uparrow|\,\rho\sigma_i\,|\uparrow\rangle + \langle\downarrow|\,\rho\sigma_i\,|\downarrow\rangle\,, \tag{3.68}$$

where $i \in \{x, y, z\}$. Substituting the density and Pauli matrices we regain Eq. (3.63) for the polarization vector of $|\chi\rangle$. Eq. (3.66) is the general form for the density matrix of a two-level system.

To illustrate the use of the expression (3.66) we recalculate $\mathcal{P}_+$ for the arbitrary spin state (3.61). For this we need the density matrix ρ_+ of the state $|+\rangle$, for which the polarization is given by $\mathbf{P} = (0, 0, 1) = \hat{\mathbf{z}}$, which means that

$$\rho_+ = \tfrac{1}{2}\left(\mathbb{1} + \sigma_z\right). \tag{3.69}$$

Using this operator we calculate with the aid of Eqs. (G.6) and (3.63c)

$$\mathcal{P}_+ = \langle\chi|\rho_+\,|\chi\rangle = \tfrac{1}{2}\left(1 + \langle\sigma_z\rangle\right) = \tfrac{1}{2}\left(1 + |a_1|^2 - |a_2|^2\right) = |a_1|^2. \tag{3.70}$$

Indeed this result coincides with that of Eq. (3.74), as it should.

Specializing Eq. (3.61) to the following special directions on the Bloch sphere, $x, y, -x, -y \leftrightarrow (\theta = \pi/2,\ \phi = 0, \pi/2, \pi, 3\pi/2)$ we obtain (see Fig. G.1)

$$\begin{aligned} |\uparrow\rangle_x &= \sqrt{\tfrac{1}{2}}\,(|\uparrow\rangle + |\downarrow\rangle) \quad\text{and}\quad |\uparrow\rangle_{-x} = \sqrt{\tfrac{1}{2}}(|\uparrow\rangle - |\downarrow\rangle) \\ |\uparrow\rangle_y &= \sqrt{\tfrac{1}{2}}(|\uparrow\rangle + i\,|\downarrow\rangle) \text{ and } |\uparrow\rangle_{-y} = \sqrt{\tfrac{1}{2}}(|\uparrow\rangle - i\,|\downarrow\rangle). \end{aligned} \tag{3.71}$$

For the negative z direction the result depends on the angle ϕ chosen for the plane of rotation. Rotating about the positive y axis we have $-z \leftrightarrow (\theta = \pi, \phi = 0)$ and obtain

$$|\uparrow\rangle_{-z} \equiv |\downarrow\rangle\,. \tag{3.72}$$

The density matrices $\rho_{x\uparrow}$ and $\rho_{y\uparrow}$ follow directly from Eqs. (3.71) and are given by

$$\rho_{x\uparrow} = \frac{1}{2}\begin{pmatrix} 1 & 1 \\ 1 & 1 \end{pmatrix} \quad\text{and}\quad \rho_{y\uparrow} = \frac{1}{2}\begin{pmatrix} 1 & -i \\ i & 1 \end{pmatrix}. \tag{3.73}$$

Note that these density matrices are idempotent and have unit trace as required for pure states.

The probability $\mathcal{P}_+$ can be expressed as the expectation values of the density operators $\rho_+ = |\uparrow\rangle\langle\uparrow|$,

$$\mathcal{P}_+ = |a_1|^2 = \langle\chi|\rho_+|\chi\rangle = \langle\rho_+\rangle, \tag{3.74}$$

and a similar relation holds for $\mathcal{P}_-$.

Problem 3.4. Consider the state $|\chi\rangle$ of a $s=\frac{1}{2}$ angular momentum system with polarization vector $\mathbf{P}$. Show that $|\chi\rangle$ is an eigenstate of the operator σ_r,

$$\sigma_r|\chi\rangle = |\chi\rangle,$$

where $\sigma_r = \mathbf{P}\cdot\boldsymbol{\sigma}$ is the operator measuring the angular momentum in the direction $\hat{\mathbf{r}} = \mathbf{P}$.

Solution. Rewriting Eq. (3.66) we have

$$\mathbf{P}\cdot\boldsymbol{\sigma} = 2\rho_\chi - \mathbb{1} \Rightarrow \sigma_r = 2|\chi\rangle\langle\chi| - \mathbb{1}.$$

Hence, $\sigma_r|\chi\rangle = (2|\chi\rangle\langle\chi| - \mathbb{1})\,|\chi\rangle = |\chi\rangle$. □

3.4 Addition of two angular momenta

In many cases of practical importance, quantum mechanical systems are characterized by more than one type of angular momentum; for instance the orbital and spin angular momenta of a single electron, or the angular momenta of two electrons in a many-electron atom. To analyze such cases we consider a closed mechanical system of two *independent* angular momenta, $\boldsymbol{j}_1$ and $\boldsymbol{j}_2$, as well as the *total* angular moment of the system,

$$\mathbf{J} = \boldsymbol{j}_1 + \boldsymbol{j}_2. \tag{3.75}$$

As $\boldsymbol{j}_1$ and $\boldsymbol{j}_2$ act in independent sectors of Hilbert space, they satisfy the commutation relations

$$[\boldsymbol{j}_1, \boldsymbol{j}_2] = 0. \tag{3.76}$$

The eigenstates of the angular momentum $\boldsymbol{j}_i$ are specified as $|j_i m_i\rangle$ in the standard representation $\{\boldsymbol{j}_i^2, j_{i\,z}\}$,with $i \in \{1,2\}$.

3.4.1 The uncoupled basis of $\boldsymbol{j}_1$ and $\boldsymbol{j}_2$

In view of the commutation of the operators $\boldsymbol{j}_1$ and $\boldsymbol{j}_2$ commute, also the operators $\boldsymbol{j}_1^2$, $j_{1\,z}$ and $\boldsymbol{j}_2^2$, $j_{2\,z}$ have to commute and this implies the existence of a joint basis (see Problem F.1) of eigenstates which can be written in the form of an ordered product, the tensor product

$$|j_1m_1; j_2m_2\rangle \equiv |j_1m_1\rangle_1 \otimes |j_2m_2\rangle_2, \tag{3.77}$$

where the eigenstates of $\boldsymbol{j}_1$ are denoted by $|j_1m_1\rangle_1$ and those of $\boldsymbol{j}_2$ by $|j_2m_2\rangle_2$. This convention is illustrated by the following examples:

$$\boldsymbol{j}_i^2\,|j_1m_1; j_2m_2\rangle = j_i(j_i+1)\hbar^2|j_1m_1; j_2m_2\rangle \tag{3.78a}$$

$$j_{iz}\,|j_1m_1; j_2m_2\rangle = m_i\hbar|j_1m_1; j_2m_2\rangle, \tag{3.78b}$$

with $i \in \{1,2\}$. The basis $\{|j_1m_1; j_2m_2\rangle\}$ is called the *uncoupled basis* of the Hilbert space of the pair. For given values of j_1 and j_2 this basis spans a $(2j_1+1)(2j_2+1)$-dimensional space, which represents the Hilbert space of the tensor $\boldsymbol{j}_1 \otimes \boldsymbol{j}_2$. In general, the states do *not* commute under the tensor product,

$$|j_1m_1\rangle_1 \otimes |j_2m_2\rangle_2 \neq |j_2m_2\rangle_2 \otimes |j_1m_1\rangle_1, \tag{3.79}$$

which means that we have to specify the order of the product, which is called *coupling order* of $\boldsymbol{j}_1$ and $\boldsymbol{j}_2$. Importantly, for the special case $m_1 = j_1$ and $m_2 = j_2$ the tensor product is independent of the coupling order,

$$|j_1j_1\rangle_1 \otimes |j_2j_2\rangle_2 = |j_2j_2\rangle_2 \otimes |j_1j_1\rangle_1. \tag{3.80}$$

This is a property of so-called *stretched* states, which will be introduced in Section 3.4.2. For the special case $j_1 = \frac{1}{2}$ and $j_2 = 1$ their independence of the coupling order is demonstrated in the example below. Note that, for given states $|j_1m_1\rangle_1$ and $|j_2m_2\rangle_2$, Eqs. (3.78) are independent of the coupling order.

Example 3.1. The product space in matrix notation

Consider two angular momenta, $\boldsymbol{j}_1$ and $\boldsymbol{j}_2$, acting in vector spaces of dimension $d_1 = 2$ and $d_2 = 3$, respectively (i.e., $j_1 = \frac{1}{2}$ and $j_2 = 1$). The corresponding eigenstates are given by

$$|\tfrac{1}{2}, +\tfrac{1}{2}\rangle = \begin{pmatrix} 1 \\ 0 \end{pmatrix}, \qquad |\tfrac{1}{2}, -\tfrac{1}{2}\rangle = \begin{pmatrix} 0 \\ 1 \end{pmatrix} \tag{3.81a}$$

and

$$|1, +1\rangle = \begin{pmatrix} 1 \\ 0 \\ 0 \end{pmatrix}, \qquad |1, 0\rangle = \begin{pmatrix} 0 \\ 1 \\ 0 \end{pmatrix}, \qquad |1, -1\rangle = \begin{pmatrix} 0 \\ 0 \\ -1 \end{pmatrix}. \tag{3.81b}$$

In the uncoupled representation the eigenstate $|\frac{1}{2}, +\frac{1}{2}; 1, 0\rangle$ is given by the tensor product $|\frac{1}{2}, +\frac{1}{2}\rangle \otimes |1, 0\rangle$. Note that $|\frac{1}{2}, +\frac{1}{2}\rangle$ and $|1, 0\rangle$ do *not* commute under the tensor product,

$$|\tfrac{1}{2}, +\tfrac{1}{2}\rangle \otimes |1, 0\rangle = \begin{pmatrix} 1 \\ 0 \end{pmatrix} \otimes \begin{pmatrix} 0 \\ 1 \\ 0 \end{pmatrix} \neq \begin{pmatrix} 0 \\ 1 \\ 0 \end{pmatrix} \otimes \begin{pmatrix} 1 \\ 0 \end{pmatrix} = |1, 0\rangle \otimes |\tfrac{1}{2}, +\tfrac{1}{2}\rangle. \tag{3.81c}$$

For the doublet state $|\frac{1}{2}, +\frac{1}{2}\rangle$ the tensor product $|\frac{1}{2}, +\frac{1}{2}\rangle \otimes |1, 0\rangle$ opens a three-dimensional subspace for the triplet state $|1, 0\rangle$. Likely, for the triplet state $|1, 0\rangle$, the tensor product $|1, 0\rangle \otimes |\frac{1}{2}, +\frac{1}{2}\rangle$ opens a two-dimensional subspace for the doublet state $|\frac{1}{2}, +\frac{1}{2}\rangle$. In both ways we obtain a 6-dimensional Hilbert space (for the tensors $\boldsymbol{j}_1 \otimes \boldsymbol{j}_2$ and $\boldsymbol{j}_2 \otimes \boldsymbol{j}_1$, respectively). Note that the states $|\frac{1}{2}, +\frac{1}{2}\rangle$ and $|1, 1\rangle$ are special because for $m_1 = j_1$ and $m_2 = j_2$ the tensor product is independent of the coupling order, a property of *stretched* states (see next section

$$|\tfrac{1}{2}, +\tfrac{1}{2}\rangle \otimes |1, 1\rangle = \begin{pmatrix} 1 \\ 0 \end{pmatrix} \otimes \begin{pmatrix} 1 \\ 0 \\ 0 \end{pmatrix} = \begin{pmatrix} 1 \\ 0 \\ 0 \end{pmatrix} \otimes \begin{pmatrix} 1 \\ 0 \end{pmatrix} = |1, 1\rangle \otimes |\tfrac{1}{2}, +\tfrac{1}{2}\rangle. \tag{3.82}$$

3.4.2 The coupled basis of $\boldsymbol{j}_1$ and $\boldsymbol{j}_2$

Realizing that $\boldsymbol{j}_1$ and $\boldsymbol{j}_2$ individually satisfy commutation relations of the type (3.1) and commute with each other it is straightforward to show that also the *total angular momentum*, given by the vector sum

$$\mathbf{J} = \boldsymbol{j}_1 + \boldsymbol{j}_2, \tag{3.83}$$

satisfies the commutation relations (3.1). This immediately implies that $\mathbf{J}$ satisfies all properties of quantized angular momentum as summarized in Section 3.1. In particular we have

$$\mathbf{J}^2 |JM\rangle = J(J+1)\hbar^2 |JM\rangle \tag{3.84a}$$

$$J_z |JM\rangle = M\hbar |JM\rangle, \tag{3.84b}$$

with M restricted to the interval

$$-J \leq M \leq J. \tag{3.85}$$

At this point we have established that the vector addition is subject to the constraint that also the resultant vector be quantized. Since $\boldsymbol{j}_1^2$ and $\boldsymbol{j}_2^2$ commute with both J_z and $\mathbf{J}^2$ (see Problem 4.6) we infer that the quantum numbers j_1, j_2, J and M are *compatible* (see Section F.1.1); i.e., they define the basis $\{|(j_1 j_2)JM\rangle\}$, the so-called *coupled* basis of the standard representation $\{J^2, J_z\}$. With the notation $(j_1 j_2)$ we specify the values as well as the *coupling order* of the two angular momenta (see Section 3.5.1). Often one writes $\{|j_1 j_2 JM\rangle\}$ or, simply $\{|JM\rangle\}$ if coupling order and values of j_1 and j_2 are irrelevant or known from the context. For given values of j_1, j_2 and J, the

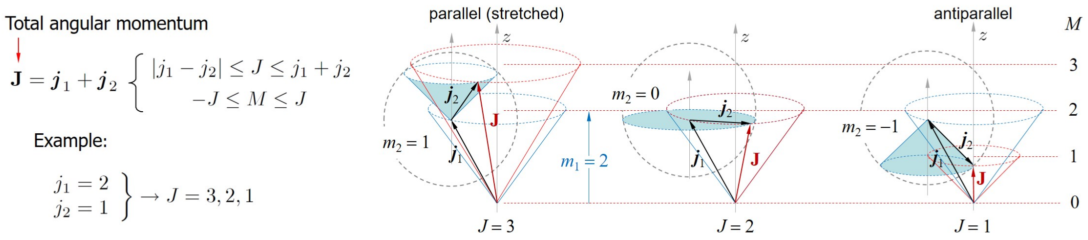


Figure 3.2: Vector addition of quantized angular momenta. The quantization conditions limit the number of possible resulting vectors. This is illustrated for the example of the angular momenta $j_1 = 2$ and $j_2 = 1$ (compare with Fig. 3.2). The state with $m_1 = j_1$ and $m_2 = j_2$ (i.e., $M = j_1 + j_2 = 3$) is called the state of *parallel coupling* or the *stretched* state as it represents the largest total angular momentum projection that can be constructed by quantized vector addition.

operator $\mathbf{J}$ acts in a $(2J+1)$-dimensional subspace of the product space of the tensor $\boldsymbol{j}_1 \otimes \boldsymbol{j}_2$, with the quantum number J restricted to the interval (see Problem 3.5),

$$|j_1 - j_2| \le J \le j_1 + j_2. \tag{3.86}$$

Denoting the lesser of j_1 and j_2 by $j_< \equiv \min\{j_1, j_2\}$, the quantum number J can take $2j_< + 1$ values (see Problem 3.6). This is illustrated geometrically in Fig. 3.2. Geometry helps to swiftly analyze the coupling options. More subtle properties (like phase relations) require the algebra of commutation relations - see Section 3.4.3.

Since angular momentum states of different J are orthogonal, the dimension of the $2j_< + 1$ allowed values of J add up to $(2j_1 + 1)(2j_2 + 1)$ as is demonstrated in Problem 3.6. Formally, the product space of $\boldsymbol{j}_1 \otimes \boldsymbol{j}_2$, represented by the *uncoupled basis*, $\{|j_1 m_1; j_2 m_2\rangle\}$, is called *reducible* because it can be decomposed into the *direct sum* of $2j_< + 1$ *irreducible* subspaces, one for each allowed value of J and represented in the coupled basis $\{|(j_1 j_2)JM\rangle\}$. As we shall find in Section 3.8 the irreducible subspaces of the coupled representation are invariant under rotations about a point. Importantly, the coupled basis and the uncoupled basis are defined irrespective of the presence (or absence) of a *coupling mechanism.*

Example 3.2. Angular momentum addition in matrix notation

Let us return to the example of two angular momenta, $\boldsymbol{j}_1$ and $\boldsymbol{j}_2$, acting in vector spaces of dimension $d_1 = 2$ and $d_2 = 3$, respectively ($j_1 = \frac{1}{2}$ and $j_2 = 1$) - see Example 3.1. Before we can add the operators $\boldsymbol{j}_1$ and $\boldsymbol{j}_2$ in the matrix representation they have to be written as operators in the $d_1 \times d_2 = 6$-dimensional Hilbert space of the tensor product $\boldsymbol{j}_1 \otimes \boldsymbol{j}_2$,

$$\mathbf{J} = \boldsymbol{j}_1 \otimes \mathbb{1}_{j_2} + \mathbb{1}_{j_1} \otimes \boldsymbol{j}_2 = \underline{\boldsymbol{j}}_1 + \underline{\boldsymbol{j}}_2,$$

where $\mathbb{1}_{j_1}$ and $\mathbb{1}_{j_2}$ are the identity matrices of the two and three dimensional subspaces in which $\boldsymbol{j}_1$ and $\boldsymbol{j}_2$ act, respectively. In this notation the operator J_z takes the form

$$J_z = \underline{j}_{1z} + \underline{j}_{2z} = \hbar \begin{pmatrix} \frac{1}{2} & 0 \\ 0 & -\frac{1}{2} \end{pmatrix} \otimes \begin{pmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{pmatrix} + \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix} \otimes \hbar \begin{pmatrix} 1 & 0 & 0 \\ 0 & 0 & 0 \\ 0 & 0 & -1 \end{pmatrix} = \hbar \begin{pmatrix} \frac{3}{2} & 0 & 0 & 0 & 0 & 0 \\ 0 & \frac{1}{2} & 0 & 0 & 0 & 0 \\ 0 & 0 & -\frac{1}{2} & 0 & 0 & 0 \\ 0 & 0 & 0 & \frac{1}{2} & 0 & 0 \\ 0 & 0 & 0 & 0 & -\frac{1}{2} & 0 \\ 0 & 0 & 0 & 0 & 0 & -\frac{3}{2} \end{pmatrix}.$$

Triangle inequality - stretching of angular momenta and pure states

The principle of quantized vector addition is illustrated in Fig. 3.2. The quantum numbers of the vector **J** satisfy the *triangle inequality.* The largest possible value of J,

$$J_{\max} = j_1 + j_2, \tag{3.87}$$

is the result of so-called *parallel coupling* of the angular momenta, pictorially referred to as the state of *stretched* angular momentum. Likewise, the smallest possible value,

$$J_{\min} = |j_1 - j_2|, \tag{3.88}$$

corresponds to the state of *antiparallel coupling.* Hence, the allowed total angular momenta differ in the level of stretching. Antiparallel coupling corresponds to *minimal stretching* and becomes *zero stretching* for $j_1 = j_2$. Parallel coupling corresponds to *maximal stretching. Complete stretching* is ruled out by the quantization condition, it is only possible in the classical limit. If either j_1 or j_2 (not both) is half-integral, J also has to be half-integral and, therefore, *nonzero.* In all other cases J can also take the value zero. Note that, $j_1 + j_2 + J$ is always *integral.*

Importantly, the eigenstates of the uncoupled basis $\{|j_1, m_1; j_2, m_2\rangle\}$ are also eigenstates of J_z. This implies the selection rule

$$M = m_1 + m_2. \tag{3.89}$$

The maximum and minimum values of M, $M = \pm(j_1 + j_2)$, correspond to *pure states* (unique eigenstates of the uncoupled representation with unit relative phase imposed by convention). In particular this holds for the so-called *stretched* state, which is the state of largest total angular momentum and projection along the quantization axis,

$$|j_1 + j_2, j_1 + j_2\rangle = |j_1, j_1; j_2, j_2\rangle. \tag{3.90}$$

Problem 3.5. Let $\boldsymbol{j}_1$ and $\boldsymbol{j}_2$ be two commuting angular momentum operators and $\mathbf{J} = \boldsymbol{j}_1 + \boldsymbol{j}_2$ the resulting total angular momentum. Show that the $2j_< + 1$ allowed values of J satisfy the inequality

$$|j_1 - j_2| \leq J \leq j_1 + j_2.$$

Solution. The maximum occurring value of M is $j_1 + j_2$; i.e., $M \leq J = j_1 + j_2$. Next we search for the minimum value of J. Without loss of generality we presume that $j_1 \geq j_2$. Considering first the case of integral M, we know that for any allowed value of J the minimal value of $|M|$ must be zero. Hence, the degeneracy of the value $M = m_1 + m_2 = 0$ gives us $2j_2$ possible vector additions consistent with the quantization rules. Hence the value $M = 0$ can only be realized for $J \geq (j_1 + j_2) - 2j_2 = j_1 - j_2$. The same result is obtained in a similar way for half-integral M. Together, the upper and lower limits provide the inequality. Subtracting the highest and lowest value of J the number of allowed J values is found to be

$$N(J) = (j_1 + j_2) - (j_1 - j_2) + 1 = 2j_2 + 1 = 2j_< + 1. \qquad \square$$

Problem 3.6. Show that the coupled basis and uncoupled basis have the same dimension.

Solution. First we recall that the uncoupled basis $\{|j_1 m_1; j_2 m_2\rangle\}$ spans a product space of dimension $d = (2j_1 + 1)(2j_2 + 1)$. For a given value of J the coupled basis $\{|(j_1 j_2)J, M\rangle\}$ spans a $(2J + 1)$-dimensional subspace of this product space. Without loss of generality we presume that $j_1 \geq j_2$. Summing over the $2j_2 + 1$ subspaces of this type we regain

$$d = \sum_{n=0}^{2j_2} [2(j_1 + j_2 - n) + 1] = (2j_2 + 1) \times [2(j_1 + j_2) + 1] - \sum_{n=0}^{2j_2} n = (2j_2 + 1)(2j_1 + 1). \qquad \square$$

3.4.3 Commutation relations for $\boldsymbol{j}_1$ and $\boldsymbol{j}_2$

The question arises how to calculate the properties of $\boldsymbol{j}_1$ and $\boldsymbol{j}_2$ with respect to the coupled basis, $\{|(j_1 j_2)JM\rangle\}$. This is not straightforward since $\boldsymbol{j}_1$ and $\boldsymbol{j}_2$ are defined with respect to the uncoupled basis, $\{|j_1 m_1; j_2 m_2\rangle\}$. Important insights can be obtained by deriving *selection rules* for the matrix elements of $j_{az}, j_{a\pm}$ in the coupled basis, with $a \in \{1,2\}$.

Starting from the commutation relations (3.1) we find for the commutation relations between J_x, J_y, J_z and j_{ax}, j_{ay}, j_{az}

$$\begin{array}{lll} [J_x, j_{ax}] = 0 & [J_y, j_{ay}] = 0 & [J_z, j_{az}] = 0 \\ [J_x, j_{ay}] = i\hbar j_{az} & [J_y, j_{az}] = i\hbar j_{ax} & [J_z, j_{ax}] = i\hbar j_{ay} \\ [J_x, j_{az}] = -i\hbar j_{ay} & [J_y, j_{ax}] = -i\hbar j_{az} & [J_z, j_{ay}] = -i\hbar j_{ax}, \end{array} \tag{3.91}$$

with $a \in \{1,2\}$. Likewise, starting from the commutation relations (3.25) we find for the commutation relations between $J_\pm, J_z$ and $j_{a\pm}, j_{az}$, with $a \in \{1,2\}$,

$$[J_\pm, j_{a\pm}] = 0, \quad [J_\pm, j_{a\mp}] = \pm 2\hbar j_{az}, \quad [J_z, j_{a\pm}] = \pm\hbar j_{a\pm}. \tag{3.92}$$

3.4.4 Selection rules for $\boldsymbol{j}_1$ and $\boldsymbol{j}_2$ in the coupled basis

From the commutation relations (3.91) and (3.92) we can derive the following *selection rules* for the matrix elements of $j_{az}, j_{a\pm}$, with $a \in \{1,2\}$, in the coupled basis $\{|J, M\rangle\}$:

S1: *The matrix elements of j_{az} are diagonal in M.*

S2: *The operators $j_{a\pm}$ raise/lower M by one.*

S3: *The matrix elements of j_{az}, and $j_{a\pm}$ are zero for $|J' - J| > 1$.*

Problem 3.7. Derive selection rule S1,

$$\langle J'M'|j_{az}|JM\rangle = 0 \quad \text{unless} \quad M' = M.$$

Solution. Using the hermiticity of J_z the selection rule S1 follows from the commutation of J_z and j_{az},

$$0 = \langle J'M'|[J_z, j_{az}]|JM\rangle = (M' - M)\hbar\langle J'M'|j_{az}|JM\rangle. \qquad \square$$

Problem 3.8. Derive selection rule S2,

$$\langle J'M'|j_{a\pm}|JM\rangle = 0 \quad \text{unless} \quad M' = M \pm 1.$$

Solution. This follows from the commutation relation $[J_z, j_{a\pm}] = \pm\hbar j_{a\pm}$. Using the hermiticity of J_z we have

$$\langle J'M'|[J_z, j_{a\pm}]|JM\rangle = (M' - M)\hbar\langle J'M'|j_{a\pm}|JM\rangle = \pm\hbar\langle J'M'|j_{a\pm}|JM\rangle,$$

which simplifies to the condition

$$(M' - M \mp 1)\hbar\langle J'M'|j_{a\pm}|JM\rangle = 0. \qquad \square$$

Problem 3.9. Derive selection rule S3,

$$\langle J'M'|j_{az}|JM\rangle = 0 \quad \text{and} \quad \langle J'M'|j_{a\pm}|JM\rangle = 0 \quad \text{for} \quad |J'-J|>1.$$

Solution. Let us assume $J' \geq J$ and write $J' = J+n$, where $n \geq 0$. Using the commutation relation $[J_+, j_{a-}] = 2\hbar j_{az}$ we have $\langle J'M'|[J_+, j_{a-}]|J, M-1\rangle = 2\hbar\langle J'M'|j_{az}|J, M-1\rangle$. Since J_+ and J_- are hermitian conjugates this relation can be rewritten in the form

$$C_{J',-M'}\langle J'M'-1|j_{a-}|J, M-1\rangle - C_{J,M-1}\langle J', M'|j_{a-}|J, M\rangle = 2\langle J'M'|j_{az}|J, M-1\rangle, \tag{a}$$

where the coefficients $C_{J,M}$ are given by Eq. (3.24b). This relation should hold for all M and M' satisfying the inequalities (b)

$$-J \leq M \leq J \quad \text{and} \quad -J' \leq M' \leq J' = J+n. \tag{b}$$

Since according to selection rule S2 we have $\langle J'M'|j_{a+}|JM\rangle = 0$ unless $M' = M+1$ and the same holds for $\langle J'M'-1|j_{a+}|JM-1\rangle = 0$, we derive from the inequalities (b) the condition

$$M \leq J+n-1 \leq J$$

to assure that Eq. (a) holds for nonzero matrix elements. As this is the case only for $0 \leq n \leq 1$, we find $\langle J'M'|j_{az}|JM\rangle = 0$ for $n > 1$. For $J' \leq J$ and for $\langle J'M'|j_{a\pm}|JM\rangle = 0$ the proof proceeds analogously. □

3.4.5 Matrix elements of j_1 and j_2 in the coupled basis - phase convention for coupling

Before we can evaluate the matrix elements of $j_{1z}, j_{1\pm}$ and $j_{2z}, j_{2\pm}$ in the coupled basis $\{|J, M\rangle\}$, with $|j_1 - j_2| \leq J \leq j_1 + j_2$, we have to introduce a new phase convention. For matrix elements diagonal in J the conditions are familiar. The operators act within a single, $(2J+1)$-dimensional subspace in which *all eigenstates carry the same phase.* This is assured by the lowering operator J_- in combination with the Condon and Shortley phase convention - see Eqs. (3.24). For matrix elements off-diagonal in J the operators act between two of such subspaces and we have to settle the relative phase by a new convention.

To elaborate on the above we consider the matrix elements of j_{1z}. In view of the selection rule S1 these are of the type $\langle J'M|j_{1z}|JM\rangle$. For $J' = J$ it follows from the hermiticity of j_{1z} that the matrix element is equal to its complex conjugate,

$$\langle JM|j_{1z}|JM\rangle = \langle JM|j_{1z}|JM\rangle^*, \tag{3.93}$$

which shows that the value of $\langle j_{1z}\rangle$ is *real*, a well know property of hermitian operators. For $J' \neq J$ the operator j_{1z} acts between two subspaces of different J for which the relative phase phase is not defined. As we shall show below, the matrix elements $\langle J'M|j_{1z}|JM\rangle$ can always be chosen to be *real* but, depending on the relative phase of $|J, M\rangle$ and $|J', M\rangle$, the sign can be positive or negative. Clearly, a new phase convention is required to remove this ambiguity.

For the matrix elements of j_{1+} the conditions are similar. In view of the selection rule S2 the matrix elements are of the type $\langle J', M+1|j_{1+}|J, M\rangle$. Since a given raising operator is the hermitian conjugate of the corresponding lowering operator we have for $J' = J$

$$\langle J, M+1|j_{1+} + j_{2+}|J, M\rangle = \langle J, M+1|j_{1+} + j_{2+}|J, M\rangle^* = C_{J,M}. \tag{3.94}$$

This shows that (as a result of the Condon and Shortley phase convention) the *sum* of the matrix elements $\langle J, M+1|j_{1+}|J, M\rangle$ and $\langle J, M+1|j_{2+}|J, M\rangle$ is *real* and *positive.* This condition can only be satisfied for arbitrary J and M if the imaginary parts of these matrix elements always cancel, which is the case if these matrix elements are *real* individually. For $J' \neq J$ we shall find (in complete analogy with the matrix elements of j_z) that a new phase convention is required to uniquely define the matrix elements of j_{1+}.

So, it will be our task to extend the Condon and Shortley phase convention with a new element to assure that the phase of the matrix elements of j_{1z} and $j_{1\pm}$ is well-defined for $J' \neq J$ in the coupled basis. For this purpose we first derive two phase rules:

(a) *For given J and J', the matrix elements of j_{1+} carry a phase which is independent of M.* Recalling the commutation relations (3.92) we consider the equation

$$\langle J', M+2|[J_+, j_{1+}]|J, M\rangle = 0. \tag{3.95}$$

Since J_+ and J_- are hermitian conjugates this equation can be rewritten in the form

$$C_{J',-M-2}\langle J', M+1|j_{1+}|J, M\rangle = C_{J,M}\langle J', M+2|j_{1+}|J, M+1\rangle, \tag{3.96}$$

where the $C_{J,M}$ are shift coefficients - see Eq. (3.24b). Note that for $-J \leq M \leq J'-2$ the ratio $C_{J',-M-2}/C_{J,M}$ is a *positive real number* in the Condon and Shortley phase convention. Hence, for given J and J', we find by induction the same phase for all values of M.

(b) *For $J' \neq J$ the matrix elements of j_{1z} and j_{2z} are equal in magnitude but opposite in sign.*

$$\langle J', M|j_{2z}|J, M\rangle = -\langle J', M|j_{1z}|J, M\rangle. \tag{3.97}$$

Since $J_z = j_{1z} + j_{2z}$ we have

$$\langle J', M|j_{1z}|J, M\rangle + \langle J', M|j_{2z}|J, M\rangle = \langle J', M|J_z|J, M\rangle = M\delta_{J,J'}, \tag{3.98}$$

For $J' \neq J$ this leads to Eq. (3.97).

At this point we introduce the following *phase convention* [36, 28]:

For $J' \neq J$ the matrix elements of j_{1z} are chosen to be real and non-negative,

$$\langle J', M|j_{1z}|J, M\rangle \geq 0. \tag{3.99}$$

The justification of this convention requires a few steps. Our goal is to show by induction that in the *off-diagonal* case ($J' \neq J$) the matrix elements $\langle J \pm 1, M|j_{1z}|J, M\rangle$ carry the opposite/same phase as $\langle J \pm 1, M+1|j_{1+}|J, M\rangle$. The procedure is based on the commutation relations (3.92) by considering the following equation:

$$\langle J', M+1|[J_+, j_{1z}]|J, M\rangle = -\hbar\langle J', M+1|j_{1+}|J, M\rangle. \tag{3.100}$$

Since J_+ and J_- are hermitian conjugates this equation can be rewritten in the form

$$C_{J',-M-1}\langle J', M|j_{1z}|J, M\rangle + \langle J', M+1|j_{1+}|J, M\rangle = C_{J,M}\langle J', M+1|j_{1z}|J, M+1\rangle. \tag{3.101}$$

We now consider two cases:

(a) $J' = J-1$: The ratio $C_{J',-M-1}/C_{J,M}$ is a positive real number in the Condon and Shortley phase convention (for all physically relevant values of M). It then follows from Eq. (3.101) that, *if the matrix element $\langle J', M|j_{1z}|J, M\rangle$ carries the same phase as $\langle J', M+1|j_{1+}|J, M\rangle$ this is also the case for $\langle J', M+1|j_{1z}|J, M+1\rangle$*. Hence, by induction this is the case for any relevant value of M. So, what remains to be done is show that for *one particular value* of J, J' and M, the matrix elements $\langle J', M|j_{1z}|J, M\rangle$ and $\langle J', M+1|j_{1+}|J, M\rangle$ carry the same phase. We claim that $M = -J'-1$ is such a particular value. For this value we have $C_{J',-M-1} = 0$ and Eq. 3.101) reduces to

$$C_{J,-J'-1}\langle J', -J'|j_{1z}|J, -J'\rangle = \langle J', -J'|j_{1+}|J, -J'-1\rangle. \tag{3.102}$$

Since the coefficient $C_{J,-J'-1} = C_{J,J'}$ is *positive* for $J' = J-1$ the phase is the same on both sides, which completes the proof by induction.

At this point we can adopt the phase convention (3.99) and find as an immediate consequence that the matrix elements of j_{1+} are *real and non-negative* for $J' = J-1$,

$$\langle J-1, M+1|j_{1+}|J, M\rangle \geq 0. \tag{3.103}$$

(*b*) $J' = J + 1$: For all relevant values of M the ratio $C_{J,M}/C_{J',-M-1}$ is real and positive in the Condon and Shortley phase convention. From Eq. (3.101) it then follows that if the phase of $\langle J', M+1|j_{1z}|J, M+1\rangle$ *is opposite to that of* $\langle J', M+1|j_{1+}|J, M\rangle$ this also applies to $\langle J', M|j_{1z}|J, M\rangle$. We claim that $M = J$ is the particular value for which this applies. Since $C_{J,M} = 0$ for $M = J$, the equation (3.101) reduces to

$$\langle J', J|j_{1z}|J, J\rangle = -(1/C_{J',-J-1})\langle J', J+1|j_{1+}|J, J\rangle. \tag{3.104}$$

Since the coefficient $C_{J',-J-1} = C_{J',J}$ is *positive* for $J' = J+1$ the matrix elements must have *opposite* phase.

At this point we can adopt the phase convention (3.99) and find for the case $J' = J + 1$ that the matrix elements of j_{1+} are *real and non-positive*,

$$\langle J+1, M+1|j_{1+}|J, M\rangle \leq 0. \tag{3.105}$$

In summary: the matrix elements of $j_{1z}, j_{1\pm}$ are *always real* in the coupled basis. By adopting the convention (3.99) we assure that for $J' \neq J$ the matrix elements $\langle J', M|j_{1z}|J, M\rangle$ are *always positive* (if not zero). The sign of the matrix elements $\langle J', M|j_{1+}|J, M\rangle$ cannot be chosen independently. Under the convention (3.99) it follows that the sign of $\langle J-1, M+1|j_{1+}|J, M\rangle$ is *positive* and that of $\langle J+1, M+1|j_{1+}|J, M\rangle$ *negative.* The convention (3.99) can be regarded as an extension of the Condon and Shortly phase convention for the off-diagonal case of the coupled basis.

3.4.6 Clebsch-Gordan basis transformation

The coupled basis is related to the uncoupled basis by a basis transformation known as the *Clebsch-Gordan transformation.* For a system of two spin-$\frac{1}{2}$ particles this is demonstrated in Problem 3.10. For arbitrary angular momenta this transformation is given by

$$|j_1 j_2 JM\rangle = \sum_{m_1=-j_1}^{j_1} \sum_{m_2=-j_2}^{j_2} |j_1 m_1; j_2 m_2\rangle\langle j_1 m_1; j_2 m_2|j_1 j_2 JM\rangle, \tag{3.106}$$

where the use of the closure relation

$$\mathbb{1} = \sum_{m_1=-j_1}^{j_1} \sum_{m_2=-j_2}^{j_2} |j_1 m_1; j_2 m_2\rangle\langle j_1 m_1; j_2 m_2| \tag{3.107}$$

does not go unnoticed. Recall that the pair state is subject to an ordering convention. The coefficients $\langle j_1 m_1; j_2 m_2|j_1 j_2 JM\rangle$ are called *Clebsch-Gordan coefficients* (CGCs). As $J_Z = j_{1z} + j_{2z}$ is diagonal in both the coupled and the uncoupled representation we find the selection rule

$$M = m_1 + m_2 \tag{3.108}$$

as a property of the CGCs - the so-called *projection rul*e. The Clebsch-Gordan transformation can be represented by a square matrix. This matrix is unitary and can be written in block-diagonal form with one block for each physically relevant value of M (see Problem 3.10). The inverse transformation is given by

$$|j_1 m_1; j_2 m_2\rangle = \sum_{J=|j_1-j_2|}^{j_1+j_2} \sum_{M=-J}^{J} |j_1 j_2 JM\rangle\langle j_1 j_2 JM|j_1 m_1; j_2 m_2\rangle, \tag{3.109}$$

where we recognize

$$\mathbb{1} = \sum_{J=|j_1-j_2|}^{j_1+j_2} \sum_{M=-J}^{J} |j_1 j_2 JM\rangle\langle j_1 j_2 JM|. \tag{3.110}$$

The CGCs are usually written in the shorthand form

$$\langle j_1m_1;j_2m_2|j_1j_2JM\rangle \Leftrightarrow \langle j_1m_1;j_2m_2|JM\rangle, \tag{3.111}$$

where the coupling order is implicitly defined by the properties of the tensor product (we return ordering issues in Section 3.5.1).

From the inner products of Eqs. (3.106) and (3.109) with their hermitian conjugates we obtain

$$\sum_{m_1=-j_1}^{j_1}\sum_{m_2=-j_2}^{j_2}\langle J'M'|j_1m_1;j_2m_2\rangle\langle j_1m_1;j_2m_2\,|JM\rangle = \delta_{J'J}\,\delta_{M'M}\,\delta(j_1j_2J) \tag{3.112a}$$

$$\sum_{J=|j_1-j_2|}^{j_1+j_2}\sum_{M=-J}^{J}\langle j_1m_1';j_2m_2'|JM\rangle\langle JM|j_1m_1;j_2m_2\rangle = \delta_{m_1'm_1}\delta_{m_2'm_2}, \tag{3.112b}$$

where $\delta(j_1j_2J)$ is a logical function of the property $\Delta(j_1j_2J)$ - see Eq. (J.12); it is *true,* $\delta(j_1j_2J)=1$, if the triangle inequalities are satisfied, i.e., for $\Delta(j_1j_2J)>0$, and *false*, $\delta(j_1j_2J)=0$, if they are violated, i.e., for $\Delta(j_1j_2J)=0$. Taking into account the projection rule (3.108) the Eqs. (3.112) reduce to a set of $2J+1$ subexpressions, one for each physically relevant value of M,

$$\sum_{m_1=-j_1}^{j_1}\langle J'M|j_1m_1;j_2,M-m_1\rangle\langle j_1m_1;j_2,M-m_1\,|JM\rangle = \delta_{J'J}\,\delta(j_1j_2J), \tag{3.113a}$$

$$\sum_{J=|j_1-j_2|}^{j_1+j_2}\langle j_1m_1';j_2,M-m_1'|JM\rangle\langle JM|j_1m_1;j_2,M-m_1\rangle = \delta_{m_1'm_1}. \tag{3.113b}$$

Problem 3.10. Find the unitary matrix U transforming the uncoupled basis $\{|j_1m_1;j_2m_2\rangle\}$ into the coupled basis $\{|j_1j_2JM\rangle\}$ for a system of two spin-$\frac{1}{2}$ particles. Write the matrix in block-diagonal form, with one block for each physically relevant value of $M\in\{-1,0,1\}$.

Solution. Starting from the Clebsch-Gordan transformation (3.106) and using Table J.2 we find the unitary matrix ($UU^\dagger=\mathbb{1}$ - see Appendix M.2.1)

$$\begin{pmatrix}|1,1\rangle\\|1,0\rangle\\|0,0\rangle\\|1,-1\rangle\end{pmatrix}=U\begin{pmatrix}|\uparrow\uparrow\rangle\\|\uparrow\downarrow\rangle\\|\downarrow\uparrow\rangle\\|\downarrow\downarrow\rangle\end{pmatrix}\quad\text{where } U=\begin{pmatrix}1&0&0&0\\0&\sqrt{1/2}&\sqrt{1/2}&0\\0&\sqrt{1/2}&-\sqrt{1/2}&0\\0&0&0&1\end{pmatrix}. \qquad \square$$

3.4.7 Recursion relations - the phase of Clebsch-Gordan coefficients

The orthonormality relations (3.112) leave us freedom to choose the phase of the CGCs. As it turns out, this freedom can be used to define the CGCs as *real* numbers, positive or negative. We start by showing this for the CGCs associated with stretched states. It follows from Eq. (3.90) that

- for given j_1 and j_2, the CGC of the *stretched state* is *unity* by convention,

$$\langle j_1j_1;j_2j_2|J_{max},J_{max}\rangle = 1, \tag{3.114}$$

where $J_{max}\equiv j_1+j_2$. To analyze the other CGCs we make repeated use of the shift operators. To explain the procedure we start by deriving two recursion relations:

1. The first recursion relation is based on the operator identity $J_- = j_{1-}+j_{2-}$,

$$\langle j_1,m_1;j_2,m_2-1|J_-|JM\rangle = \langle j_1,m_1;j_2,m_2-1|j_{1-}+j_{2-}|JM\rangle. \tag{3.115}$$

Note that we added commas in the notation where this improved the readability. As raising and lowering are hermitian conjugate operations we obtain (using the symmetry relation $C_{j_2,m_2-1} = C_{j_2,-m_2}$) the following recursion relation for given j_1, j_2 and J,

$$\begin{aligned} C_{J,-M}\langle j_1,m_1;j_2,m_2-1|J,M-1\rangle = C_{j_1,m_1}\langle j_1,m_1+1;j_2,m_2-1|JM\rangle \\ + C_{j_2,-m_2}\langle j_1m_1;j_2m_2|JM\rangle, \end{aligned} \tag{3.116}$$

subject to the selection rule (3.108), $m_1+m_2=M$.

2. The second recursion relation is based on the operator identity $J_+ = j_{1+} + j_{2+}$,

$$\langle j_1,m_1;j_2,m_2+1|J_+|J,M\rangle = \langle j_1,m_1;j_2,m_2+1|j_{1+}+j_{2+}|J,M\rangle. \tag{3.117}$$

As raising and lowering are hermitian conjugate operations we obtain for given j_1, j_2 and J,

$$\begin{aligned} C_{J,M}\langle j_1m_1;j_2,m_2+1\,|J,M+1\rangle = C_{j_1,-m_1}\langle j_1,m_1-1;j_2,m_2+1|J,M\rangle \\ + C_{j_2,m_2}\langle j_1m_1;j_2m_2|J,M\rangle, \end{aligned} \tag{3.118}$$

subject to the selection rule $m_1+m_2=M$.

To proceed we focus on two special cases:

- Recursion relation (3.116) specialized to the case $m_1=j_1$. Since $C_{j_1,m_1} = C_{j_1,j_1} = 0$, the relation reduces to

  $$\langle j_1j_1;j_2,m_2-1|J,M-1\rangle = C_{j_2,-m_2}/C_{J,-M}\langle j_1j_1;j_2m_2|JM\rangle. \tag{3.119}$$

  The ratio $C_{j_2,-m_2}/C_{J,-M}$ is *positive* in the Gordon and Shortley phase convention (for all physically relevant values of m_2 and M). Hence, for given j_1, j_2 and J, the phase of the coefficients $\langle j_1j_1;j_2m_2|JM\rangle$ is *independent of M.*

- Recursion relation (3.118) specialized to the case to $M=J$. Since $C_{J,M} = C_{J,J} = 0$, the relation reduces to

  $$\langle j_1,m_1-1;j_2,m_2+1|JJ\rangle = -C_{j_2,m_2}/C_{j_1,-m_1}\langle j_1m_1;j_2m_2|JJ\rangle, \tag{3.120}$$

  The ratio $C_{j_2,m_2}/C_{j_1,-m_1}$ is *positive* in the Gordon and Shortley phase convention (for all physically relevant values of m_1 and m_2). Hence, for given j_1, j_2 and J, the phase of the coefficient $\langle j_1m_1;j_2m_2|JJ\rangle$ is conserved up to a *sign*, which *alternates* when changing m_1 in unit steps.

With the above findings we established the following: if *one* of the coefficients $\langle j_1m_1;j_2m_2|J,M\rangle$ is real, all CGCs with the same combination of j_1, j_2 and J are *real* in the Condon and Shortley phase convention. Importantly, this condition can always be satisfied because, for given j_1, j_2 and J, we have the freedom to choose the CGCs with $m_1=j_1$ and $M=J$ to be *real* and *positive* (*sign convention*) - see Problem 3.11

$$\langle j_1j_1;j_2m_2|J,J\rangle \geq 0, \tag{3.121}$$

with $m_2 = J-j_1$. The above rules can be traced down in the tables of Appendix J.

Problem 3.11. Show that, for given j_1, j_2 and J, the Clebsch-Gordan coefficient with $m_1 = j_1$ and $M = J$ can be chosen to be *real* and *non-negative* - see Eq. (3.121).

Solution. We start with phase rule 3.103 for the special case $M = J$,

$$\langle J+1, J+1|j_{1+}|J, J\rangle \leq 0,$$

which is based on the Condon and Shortley phase convention. We insert the closure relation (3.107) before and after the operator j_+. Applying the selection rules $J = m_1 + m_2$ and $J + 1 = m_1' + m_2'$, the four-fold summation over m_1, m_2, m_1' and m_2' reduces to a two-fold summation over m_1 and m_1', with $m_2' = J{+}1{-}m_1'$. As m_2 is conserved by j_{1+} the summation over m_1' reduces to a single term, defined by $m_1' = J + 1 - m_2 = m_1 + 1$. This leaves us with the summation over m_1,

$$\sum_{m_1}\langle J+1, J+1|j_1, m_1+1; j_2, J-m_1\rangle\langle j_1, m_1+1|j_{1+}|j_1 m_1\rangle\langle j_1 m_1; j_2, J-m_1|J, J\rangle \leq 0.$$

Note that each term of the summation has to be negative (or zero) because, in view of 3.119, all $2j_1 + 1$ terms carry the *same* phase. In particular, we have for the term with $m_1 = j_1 - 1$,

$$\langle J+1, J+1|j_1, j_1; j_2, m_2\rangle C_{j_1,j_1-1}\langle j_1, j_1-1; j_2, m_2|J, J\rangle \leq 0.$$

We now have to choose a phase convention such that this inequality is satisfied. This requires that the two CGCs be real and have opposite sign because $\langle j_1, m_1+1|j_{1+}|j_1 m_1\rangle = C_{j_1,m_1}$ is real and non-negative in the Condon and Shortley phase convention. As the two CGCs differ in m_1 by one unit of angular momentum, this is achieved by adopting the convention 3.121. □

Problem 3.12. Show that the CGCs with $M = J$ satisfy the following relation

$$\langle j_1, m_1-1; j_2, m_2+1|JJ\rangle = (-1)^{j_1-m_1} C_{j_2,m_2}/C_{j_1,-m_1}\langle j_1 m_1; j_2 m_2|JJ\rangle.$$

Solution. In view of the property 3.121, we know that (for given j_1, j_2 and J) $\langle j_1 m_1; j_2, m_2|JJ\rangle$ is positive for $m_1 = j_1$ and $|j_1 - j_2| \leq J \leq j_1 + j_2$. Since the sign alternates with m_1 we find the desired relation by writing the sign in Eq. (3.120) in the form of the phase factor $(-1)^{j_1-m_1}$. □

Problem 3.13. Show that when lowering M by lowering m_2 in the CGC of the stretched state we obtain

$$\langle j_1 j_1; j_2, j_2-1|J_{max}, J_{max}-1\rangle = \sqrt{j_2/(j_1+j_2)}\langle j_1 j_1; j_2 j_2|J_{max} J_{max}),$$

which *is real* and *positive.*

Solution. Specializing Eq. (3.119) to the stretched case ($m_1 = j_1$, $m_2 = j_2$, $M = J = J_{max} = j_1 + j_2$) we have $C_{j_2,-m_2} = C_{j_2,-j_2} = \sqrt{2j_2}$ and $C_{J,-M} = C_{J,-J} = \sqrt{2J}$, and obtain the desired relation. In view of Eq. (3.114) the result is real and positive. □

Problem 3.14. Show that the CGC for antiparallel coupling of equal angular momenta is given by

$$\langle j, m; j, -m|00\rangle = \frac{(-1)^{j-m}}{\sqrt{2j+1}}.$$

Solution. Antiparallel coupling of two equal angular momenta ($j_1 = j_2 = j$) corresponds to $J = M = 0$. In this case all CGC are of the type $\langle j, m; j, -m|00\rangle$, with $-j \leq m \leq j$. These CGCs all have the same magnitude but differ in sign (see Problem 3.12),

$$\langle j, m-1; j, -m+1|00\rangle = (-1)^{j-m}\langle j, m; j, -m|00\rangle.$$

Secondly, using the sum rule 3.113a we find

$$\sum_{m=-j}^{j} |\langle jm; j, -m\,|00\rangle\,|^2 = (2j+1)|\langle j, j; j, -j|00\rangle|^2 = 1.$$

Since $\langle j, j; j, -j|00\rangle \geq 0$ by convention (3.121), the two relations lead us to the desired result. □

3.5 Symmetry properties of Clebsch-Gordan coefficients

3.5.1 Coupling order and exchange symmetry

Let us have a closer look at the coupling order introduced in Section 3.4.1. To reveal its signature we consider the matrix elements of j_{1z} for a given coupling order

$$\langle (j_1 j_2)J'M|j_{1z}|(j_1 j_2)JM\rangle. \tag{3.122}$$

Let us first focus on the *off-diagonal* case ($J' \neq J$). Adopting the convention (3.99), the off-diagonal matrix elements of j_{1z} are *real and non-negative*,

$$\langle (j_1 j_2)J'M|j_{1z}|(j_1 j_2)JM\rangle \geq 0. \tag{3.123}$$

Furthermore, recalling Eq. (3.97) we know that the off-diagonal matrix elements of j_{1z} and j_{2z} are equal in magnitude but have opposite sign,

$$\langle (j_1 j_2)J'M|j_{2z}|(j_1 j_2)JM\rangle = -\langle (j_1 j_2)J'M|j_{1z}|(j_1 j_2)JM\rangle. \tag{3.124}$$

Our task is to apply this *convention* to a system of two angular momenta, say $\boldsymbol{j}_a$ and $\boldsymbol{j}_b$. By assigning the values $\boldsymbol{j}_a \to \boldsymbol{j}_1$ and $\boldsymbol{j}_b \to \boldsymbol{j}_2$ we have for $J' = J-1$

$$\langle (j_a j_b)(J-1),M|j_{az}|(j_a j_b)JM\rangle \geq 0 \quad \text{and} \quad \langle (j_a j_b)(J-1),M|j_{bz}|(j_a j_b)JM\rangle \leq 0. \tag{3.125a}$$

On the other hand, by assigning $\boldsymbol{j}_b \to \boldsymbol{j}_1$ and $\boldsymbol{j}_a \to \boldsymbol{j}_2$ we have

$$\langle (j_b j_a)(J-1),M|j_{bz}|(j_b j_a)JM\rangle \geq 0 \quad \text{and} \quad \langle (j_b j_a)(J-1),M|j_{az}|(j_b j_a)JM\rangle \leq 0. \tag{3.125b}$$

This shows that, by *changing the coupling order*, we *also change the sign* of the *off-diagonal* matrix elements of j_{az} (and j_{bz}),

$$\langle (j_a j_b)(J-1),M|j_{az}|(j_a j_b)JM\rangle = -\,\langle (j_b j_a)(J-1),M|j_{az}|(j_b j_a)JM\rangle. \tag{3.126}$$

First we consider the coupling order $(j_a j_b)$. What can we say about the phase of $|(j_a j_b)JM\rangle$? First of all, for given J, all angular momentum states carry the same phase since the phase is independent of M in the Condon and Shortley phase convention - see Eqs. (3.24). Extending this convention by adopting (3.99) we know that the matrix elements $\langle (j_a j_b)(J-1),M|j_{az}|(j_a j_b)JM\rangle$ are real and *positive* for any physically relevant value of M. So, if the phase of $|(j_a j_b)J,M\rangle$ is real and *positive* for one particular value of J, this is also the case for the state $|(j_a j_b)(J-1),M\rangle$ and (by induction) for all physically relevant values of J. This particular state exists because the stretched state $|(j_a j_b)J_{max},J_{max}\rangle$, with $J_{max} = j_a + j_b$, has unit phase by convention - see Eq. (3.90).

What about the other coupling order? As in the previous case, for given J the states $|(j_b j_a)JM\rangle$ carry the same phase (independent of M). However, in view of Eq. (3.124) the matrix elements $\langle (j_b j_a)(J-1),M|j_{az}|(j_b j_a)JM\rangle$ are real and *negative.* So, if the phase of $|(j_b j_a)JM\rangle$ is real and *positive* for one particular value of J it has to be real and *negative* for $|(j_b j_a)(J-1),M\rangle$ and (by induction) *alternate between positive and negative* for all physically relevant values of J. Also in the present case this particular value exists because, recalling Eq. (3.80), the *stretched* state has unit phase, irrespective of the coupling order, $|(j_a j_b)J_{max},J_{max}\rangle = |(j_a j_b)J_{max},J_{max}\rangle$. Accordingly, the phase of the states $|(j_b j_a)J,M\rangle$ is real and alternates between positive and negative in such a way that it is positive for the stretched state. Thus, comparing both coupling orders, we arrive at

$$|(j_b j_a)J,M\rangle = (-1)^{j_a+j_b-J}|(j_a j_b)J,M\rangle. \tag{3.127}$$

About the *diagonal* case ($J' = J$) we can be short since the phase drops out the matrix element (3.122). Also the *off-diagonal* matrix elements with $|J'-J| > 1$ do not add new conditions on the phase. These can be disregarded as nonphysical as they violate the selection rule S3. Recalling the equivalence (3.111) we find from Eq. (3.127) for the symmetry relation of CGCs

$$\langle j_b m_b; j_a m_a|J,M\rangle = (-1)^{j_a+j_b-J}\langle j_a m_a; j_b m_b|J,M\rangle. \tag{3.128}$$

3.5.1.1 Exchange symmetry for identical particles

The case of equal spin, $j_1 = j_2 = j$, deserves special attention in view of its importance for the exchange symmetry of identical particles. In this case one cannot distinguish between the two coupling orderings and we have to add the amplitudes. This can be done in two independent ways. In particular in the form of a symmetric (+) and a antisymmetric (−) linear combination,

$$\begin{aligned}|jjJM\rangle_{\pm} &= \sqrt{\tfrac{1}{2}}\,[|(j_1j_2)J,M\rangle \pm |(j_2j_1)J,M\rangle]\\ &= \sqrt{\tfrac{1}{2}}\left[1 \pm (-1)^{2j-J}\right]|(j_1j_2)J,M\rangle. \end{aligned} \tag{3.129}$$

Note that the second line vanishes for certain combinations of j and J. These combinations are excluded by the exchange symmetry. For the coupling of *integer* spins the value of $J_{max} = 2j$ is always *even*, whereas for *half-integer* spins it is always *odd*. As a consequence, for *integer* spins the *even* (*odd*) total spin states are *symmetric* (*antisymmetric*) whereas for *half-integer* spins this is the case for *odd* (*even*) total spin. In particular, for half-integer spins the stretched pair states are symmetric for odd J, whereas for integer spins this is the case for even J. These symmetry rules are known from some well-known examples. For instance, for two identical particles without spin the total spin is zero. In this case the spin of the pair is even and the corresponding state symmetric under exchange. For two identical spin-$\frac{1}{2}$ particles the total spin can be 0 or 1. In this case the spin is half-integer. For total spin zero (which is even) the corresponding spin state is antisymmetric under exchange; for $J = 1$ (which is odd) the spin state of the pair is symmetric.

Problem 3.15. For antiparallel coupling of two equal angular momenta, $j_1 = j_2 = j$, the total angular momentum is zero, $J = M = 0$. Show that in this case the Clebsch-Gordan decomposition (3.106) can be written in the form

$$\sqrt{2j+1}|jj00\rangle = \sum_m (-1)^{j-m}|j,m;j,-m\rangle.$$

Solution. We start from the Clebsch-Gordan decomposition (3.106) for the special case $j_1 = j_2 = j$,

$$|jjJM\rangle = \sum_{m_1,m_2} |jm_1;jm_2\rangle\langle jm_1;jm_2|jjJM\rangle.$$

For antiparallel coupling the total angular momentum is zero, $J = M = 0$. Using the selection rule $M = m_1 + m_2$ the decomposition takes the form

$$|jj00\rangle = \sum_m |j,m;j,-m\rangle\langle j,m;j,-m|jj00\rangle.$$

Substituting

$$\langle j,m;j,-m|00\rangle = \frac{(-1)^{j-m}}{\sqrt{2j+1}}$$

(see Problem 3.14) we arrive at the desired result. □

3.5.2 Time-reversal symmetry

Thus far we analyzed the addition of angular momenta, $\boldsymbol{j}_3 = \boldsymbol{j}_1 + \boldsymbol{j}_2$. What about subtraction? As suggested by the vector model (see Fig. 3.3) we would like to define $\boldsymbol{j}_2 = \boldsymbol{j}_3 - \boldsymbol{j}_1$ by introducing a new angular momentum operator $\bar{\boldsymbol{j}} = -\boldsymbol{j}$, which has the properties of a "reversed" angular momentum. As it turns out, to properly define $\bar{\boldsymbol{j}}$ we have to study $\boldsymbol{j}$ under *time reversal*. A complicating factor is that the transformation $\boldsymbol{j} \mapsto \bar{\boldsymbol{j}}$ is found to be antilinear [96]. All this being said, we shall not enter into the properties of antilinear maps because, within the Condon and Shortley phase convention, the symmetry properties of the CGCs can be obtained algebraically from the recursion relations 3.116 and 3.118.

In this section we derive the relation

$$\langle j_2,-m_2;j_3,m_3|j_1m_1\rangle = (-1)^{j_2+m_2}\left(\frac{2j_1+1}{2j_3+1}\right)^{1/2}\langle j_1m_1;j_2m_2|j_3m_3\rangle, \tag{3.130}$$

where quantum numbers were chosen in compliance with the vector model. The prefactor will follow from the recursion relations.

We start by renaming $J \to j_3$ and $M \to m_3$ in the recursion relations 3.116 and 3.118. With some rearrangement we bring these relations in the form

$$\begin{aligned} C_{j_1,m_1}\langle j_1, m_1+1; j_2, m_2-1|j_3m_3\rangle = &-C_{j_2,-m_2}\langle j_1m_1; j_2m_2|j_3m_3\rangle \\ &+ C_{j_3,-m_3}\langle j_1m_1; j_2, m_2-1|j_3, m_3-1\rangle, \end{aligned} \tag{3.131a}$$

$$\begin{aligned} C_{j_1,-m_1}\langle j_1, m_1-1; j_2, m_2+1|j_3m_3\rangle = &-C_{j_2,m_2}\langle j_1m_1; j_2m_2|j_3m_3\rangle \\ &+ C_{j_3,m_3}\langle j_1m_1; j_2, m_2+1|j_3, m_3+1\rangle. \end{aligned} \tag{3.131b}$$

Note that both equations satisfy the selection rule

$$m_1 + m_2 = m_3. \tag{3.132}$$

Now we relable the indices cyclicly, $(1,2,3) \to (2,3,1)$,

$$\begin{aligned} C_{j_1,-m_1}\langle j_2m_2; j_3, m_3-1|j_1, m_1-1\rangle = &\, C_{j_2,m_2}\langle j_2, m_2+1; j_3, m_3-1|j_1m_1\rangle \\ &+ C_{j_3,-m_3}\langle j_2m_2; j_3m_3|j_1m_1\rangle. \end{aligned} \tag{3.133}$$

Note that in this process the selection rule 3.132 was replaced by $m_2 + m_3 = m_1$. As suggested by the vector model (see Fig. 3.3), the selection rule 3.132 can be restored by renaming the quantum number $m_2 \to -m_2$. However, we can do better. By renaming $m_2 \to -m_2 - 1$ and $m_3 \to m_3 + 1$ we not only recover the selection rule 3.132 but find that $\langle j_2, -m_2; j_3, m_3|j_1m_1\rangle$ satisfies, *up to a sign*, the "other" recursion relation, Eq. 3.131b,

$$\begin{aligned} C_{j_1,-m_1}\langle j_2, -(m_2+1); j_3m_3|j_1, m_1-1\rangle = &\, C_{j_2,m_2}\langle j_2, -m_2; j_3m_3|j_1m_1\rangle \\ &+ C_{j_3,m_3}\langle j_2, -(m_2+1); j_3m_3+1|j_1m_1\rangle. \end{aligned} \tag{3.134}$$

Note that we used the symmetry rules $C_{j_2,-m_2-1} = C_{j_2,m_2}$ and $C_{j_3,-m_3-1} = C_{j_3,m_3}$. To obtain full equivalence, *including the sign*, we compare Eqs. (3.134) and (3.131b) term by term and add the appropriate phase factor,

$$-\langle j_1, m_1-1; j_2, m_2+1|j_3m_3\rangle = (-1)^{j_2+(m_2+1)}\alpha\langle j_2, -(m_2+1); j_3m_3|j_1, m_1-1\rangle \tag{3.135a}$$

$$\langle j_1m_1; j_2m_2|j_3m_3\rangle = (-1)^{j_2+m_2}\alpha\langle j_2, -m_2; j_3m_3|j_1m_1\rangle \tag{3.135b}$$

$$-\langle j_1m_1; j_2, m_2+1|j_3, m_3+1\rangle = (-1)^{j_2+(m_2+1)}\alpha\langle j_2, -(m_2+1); j_3m_3+1|j_1m_1\rangle. \tag{3.135c}$$

Here α is a proportionality constant, independent of m_1, m_2 and m_3. Since $j_2 + m_2$ is always integral and the CGCs always real, α is a real number, which may still depend on j_1, j_2 and j_3.

To determine sign and magnitude of α, we start by applying the exchange rule (3.127) to bring Eq. (3.135b) in the form

$$\langle j_1m_1; j_2m_2|j_3m_3\rangle = (-1)^{j_2+m_2}(-1)^{j_2+j_3-j_1}\alpha\langle j_3m_3; j_2, -m_2|j_1m_1\rangle. \tag{3.136}$$

First we shall demonstrate that the sign of α is *positive*. For given j_1, j_2, j_3, the relations (3.135) hold for all physically meaningful values of m_1, m_2, m_3. Therefore, we can determine the sign of α by considering a special case. For $m_1 = j_1$ and $m_3 = j_3$, Eq. (3.136) becomes

$$\langle j_1j_1; j_2m_2|j_3j_3\rangle = (-1)^{j_2+m_2}(-1)^{j_2+j_3-j_1}\alpha\langle j_3j_3; j_2, -m_2|j_1j\rangle. \tag{3.137}$$

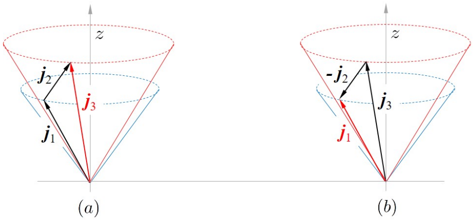

Figure 3.3: Vector addition diagrams; (a) diagram for $j_3 = \boldsymbol{j}_1 + \boldsymbol{j}_2$; (b) diagram for $j_1 = \boldsymbol{j}_3 + (-\boldsymbol{j}_2)$. The figure is very suggestive but the addition of a "reversed" angular momentum cannot be properly defined within the vector model. This model handles the quantum numbers but does not capture the phase rules.

From the selection rule 3.132 we infer that $m_2 = j_3 - j_1$ and since $j_2 + j_3 - j_1$ is always integral the Eq. (3.136) simplifies to

$$\langle j_1 j_1; j_2 m_2 | j_3 j_3\rangle = \alpha \langle j_3 j_3, j_2, -m_2 | j_1 j_1\rangle. \tag{3.138}$$

Hence, in view of the convention (3.121) we find $\alpha > 0$.

To determine the magnitude of α we compare the moduli of the two sides of Eq. (3.136),

$$|\langle j_1 m_1; j_2, m_3 - m_1 | j_3, m_3\rangle|^2 = |\alpha|^2 |\langle j_3 m_3; j_2, m_1 - m_3; | j_1 m_1\rangle|^2$$

Summing the l.h.s. over j_1 and the r.h.s. over j_3 we find by unitarity - see sum rule (3.113a),

$$\sum_{m_3=-j_3}^{j_3} \delta(j_1 j_2 j_3) = |\alpha|^2 \sum_{m_1=-j_1}^{j_1} \delta(j_1 j_2 j_3). \tag{3.139}$$

Since $\alpha > 0$ we find for the magnitude of α,

$$\alpha = \left(\frac{2j_3+1}{2j_1+1}\right)^{1/2}. \tag{3.140}$$

Substituting this value in Eq. (3.135b) we arrive at Eq. (3.136)

$$\langle j_2, -m_2; j_3, m_3 | j_1 m_1\rangle = (-1)^{j_2+m_2} \left(\frac{2j_1+1}{2j_3+1}\right)^{1/2} \langle j_1 m_1; j_2 m_2 | j_3 m_3\rangle. \tag{3.141}$$

Other symmetry relations can be derived in same way but rather than presenting these separately we introduce in the next section the Wigner $3j$ symbols. These are best suited to deal with the symmetry properties of the CGCs.

It is instructive to consider the stretched case, $m_1 = j_1$, $m_2 = j_2$ and $m_3 = j_3 = j_1 + j_2$,

$$\langle j_2, -j_2; j_3, j_3 | j_1 j_1\rangle = (-1)^{2j_2} \left(\frac{2j_3+1}{2j_1+1}\right)^{1/2} \langle j_1 j_1; j_2 j_2 | j_3 j_3\rangle. \tag{3.142}$$

This expression shows that the reversal is accompanied by a phase factor $(-1)^{2j_2}$, which is unity for integer j_2 but introduces a sign change in the half-integer case. This sign change is typical for time reversal of angular momenta without a classical analog [96].

3.5.3 Wigner $3j$ symbols

An inconvenience of CGCs are the non-intuitive symmetry properties, not to speak of the forest of competing notations in the literature.[1] This spoils the joy of rapid manipulation and assessment.

---

[1] A compilation of notation conventions is given by Edmonds [36].

An important simplification results by expressing the CGCs in terms of Wigner $3j$ symbols. These are obtained by treating the three angular momenta on equal footing. For this purpose we note that the kets of the basis $\{|j,m\rangle\}$ are related to the bras of the hermitian conjugate basis $\{\langle j,m|\}$ by the transformation

$$\langle j,m| = \sum_{m'} g_{m,m'}|j,m'\rangle, \tag{3.143}$$

where $g_{m,m'}$ is a metric tensor,

$$g_{m,m'} = \binom{j}{m\,m'} = (-1)^{j+m}\delta_{m,m'}, \tag{3.144}$$

in the notation of Wigner. Note that $j+m$ is always an integer. The kets transform as contravariant vectors and the bras as covariant vectors. In tensor calculus the transformation (3.143) is known as *lowering* of the contravariant index. By lowering of the indices m_1 and m_2 the CGCs take the form

$$\langle j_1m_1; j_2m_2|j_3m_3\rangle = (-1)^{j_1+m_1}(-1)^{j_2+m_2}|j_1m_1\rangle \otimes |j_2m_2\rangle \otimes |j_3m_3\rangle. \tag{3.145}$$

Since the CGCs are real constants the tensor $|j_1m_1\rangle \otimes |j_2m_2 \otimes |j_3m_3\rangle$ must be a real scalar; i.e., be invariant under rotation. We denote this scalar by the expression

$$(-1)^{-2j_2}\sqrt{2j_3+1}\begin{pmatrix} j_1 & j_2 & j_3 \\ m_1 & m_2 & -m_3 \end{pmatrix}, \tag{3.146}$$

where the factor in brackets is the Wigner $3j$ symbol. Actually, at this point there is no reason to put the prefactor in front of the $3j$ symbol and/or the minus sign in front of m_3. However, we are free to do so and as we shall see this choice maximizes the symmetry. Using the projection rule $m_1 + m_2 = m_3$ the relation between the CGC and the $3j$ symbol becomes

$$\langle j_1m_1; j_2m_2|j_3m_3\rangle = (-1)^{j_1-j_2+m_3}\sqrt{2j_3+1}\begin{pmatrix} j_1 & j_2 & j_3 \\ m_1 & m_2 & -m_3 \end{pmatrix}, \tag{3.147}$$

or, equivalently,

$$\begin{pmatrix} j_1 & j_2 & j_3 \\ m_1 & m_2 & -m_3 \end{pmatrix} = \frac{(-1)^{j_1-j_2+m_3}}{\sqrt{2j_3+1}}\langle j_1m_1; j_2m_2|j_3m_3\rangle. \tag{3.148}$$

Note that $j_1 - j_2 + m_3$ is always integral.

3.5.3.1 Properties of $3j$ symbols

The $3j$ symbols inherit their *principal properties* from the CGCs. So, the $3j$ symbols are *zero unless*

1. The *triangle inequality* holds, $\Delta(j_1j_2j_3) > 0$ - see Eq. (J.12);
2. The *sum* of the angular momenta is *integral*, $j_1 + j_2 + j_3 \in \mathbb{Z}$.
3. The angular momentum *projection is conserved*, $m_1 + m_2 + m_3 = 0$.

The *symmetry properties* are given by two easy-to-memorize rules:

1. *Invariance* under *cyclic* permutations of the columns
2. *Phase changes by* $(-1)^{j_1+j_2+j_3}$
   a. under *exchange* of two columns
   b. under *inverted projection*, $m_1, m_2, m_3 \to -m_1, -m_2, -m_3$.

The symmetry properties $2a$ and $2b$ are derived in Problems 3.16 and 3.17.

3.5.3.2 Sum rules

From the *orthonormality relations* (3.112) immediately follow the following *sum rules*:

$$\sum_{j_3=|j_1-j_2|}^{j_1+j_2} \sum_{m_3=-j_3}^{j_3} (2j+3) \begin{pmatrix} j_1 & j_2 & j_3 \\ m_1 & m_2 & m_3 \end{pmatrix}^2 = 1 \tag{3.149a}$$

$$\sum_{m_1=-j_1}^{j_1} \sum_{m_2=-j_2}^{j_2} (2j+3) \begin{pmatrix} j_1 & j_2 & j_3 \\ m_1 & m_2 & m_3 \end{pmatrix}^2 = 1. \tag{3.149b}$$

Note that the second summations can be eliminated by applying the projection rule.

Problem 3.16. Derive the *symmetry property* 2*a,*

$$\begin{pmatrix} j_2 & j_1 & j_3 \\ m_2 & m_1 & m_3 \end{pmatrix} = (-1)^{j_1+j_2+j_3} \begin{pmatrix} j_1 & j_2 & j_3 \\ m_1 & m_2 & m_3 \end{pmatrix}.$$

Solution. Converting Eq. (3.128) to $3j$ symbols we find

$$(-1)^{j_2-j_1-m_3}\sqrt{2j_3+1} \begin{pmatrix} j_2 & j_1 & j_3 \\ m_2 & m_1 & m_3 \end{pmatrix} = (-1)^{j_1+j_2-j_3}(-1)^{j_1-j_2-m_3}\sqrt{2j_3+1} \begin{pmatrix} j_1 & j_2 & j_3 \\ m_1 & m_2 & m_3 \end{pmatrix}.$$

This can be rewritten in the form

$$\begin{pmatrix} j_2 & j_1 & j_3 \\ m_2 & m_1 & m_3 \end{pmatrix} = (-1)^{4j_1-j_1-j_2-j_3} \begin{pmatrix} j_1 & j_2 & j_3 \\ m_1 & m_2 & m_3 \end{pmatrix}.$$

Since $4j_1$ is always *even* and $j_1 + j_2 + j_3$ always *integral* this corresponds to the desired property. □

Problem 3.17. Derive the *symmetry property* 2*b,*

$$\begin{pmatrix} j_1 & j_2 & j_3 \\ -m_1 & -m_2 & -m_3 \end{pmatrix} = (-1)^{j_1+j_2+j_3} \begin{pmatrix} j_1 & j_2 & j_3 \\ m_1 & m_2 & m_3 \end{pmatrix}.$$

Solution. Converting Eq. (3.130) to $3j$ symbols we find

$$(-1)^{j_2-j_3+m_1}\sqrt{2j_1+1} \begin{pmatrix} j_2 & j_3 & j_1 \\ -m_2 & m_3 & -m_1 \end{pmatrix} = (-1)^{j_2+m_2}\left(\frac{2j_1+1}{2j_3+1}\right)^{1/2}(-1)^{j_1-j_2+m_3}\sqrt{2j_3+1} \begin{pmatrix} j_1 & j_2 & j_3 \\ m_1 & m_2 & -m_3 \end{pmatrix}.$$

Using the *projection rule*, $m_3 = m_1 + m_2$, this can be rewritten in the form

$$\begin{pmatrix} j_2 & j_3 & j_1 \\ -m_2 & m_3 & -m_1 \end{pmatrix} = (-1)^{2m_2-2j_2}(-1)^{j_1+j_2+j_3} \begin{pmatrix} j_1 & j_2 & j_3 \\ m_1 & m_2 & -m_3 \end{pmatrix}.$$

Note that $2m_2 - 2j_2$ is always *even.* So, after cyclic rotation of the l.h.s. and renaming $m_3 \to -m_3$ this corresponds to the desired property. □

3.5.3.3 Vector model for $3j$ symbols

In Fig. 3.4 the $3j$ symbols are illustrated by diagrams in which the vectors add up to zero (note the difference with Fig. 3.2). With such diagrams the validity of the triangle inequality and the projection rule are easily established. As *most* combinations of the indices turn out to be nonphysical, rapid disposal of these combinations greatly enhances the efficiency of calculations. Only if a $3j$ symbol is *not* manifestly zero it has to be evaluated. Beware that not being *manifestly* zero does not exclude being zero. This happens in some high symmetry cases as a consequence of the symmetry rules. Many properties of $3j$ symbols are summarized in Appendix J.

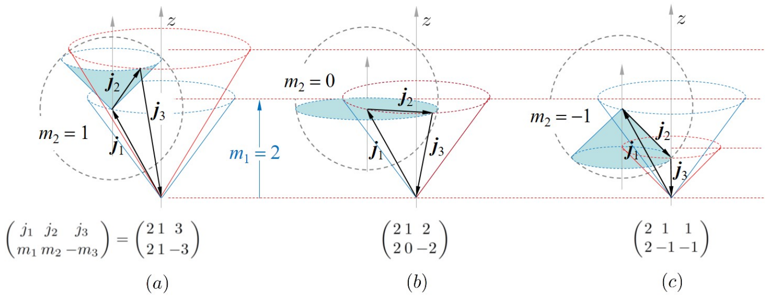

Figure 3.4: Graphical representation of $3j$ symbols with $j_1 = 2$, $j_2 = 1$: a.) $j_3 = 3$; b.) $j_3 = 2$; c.) $j_3 = 1$. The $3j$ symbol is valid (i.e., not manifestly zero) if the triangle is closed and the projections onto the z axis are quantized in integer values. This implies that the triangle inequality is satisfied, $j_1 + j_2 + j_3$ is integral, and the projections onto the z axis add up to zero, $m_1 + m_2 + m_3 = 0$. The phase rules are not captured in these diagrams.

3.6 Addition in the presence of coupling - conservation rules

Let us continue with the closed mechanical system of two angular momenta introduced above. Let $\boldsymbol{j}_1$ and $\boldsymbol{j}_2$, with $[\boldsymbol{j}_1, \boldsymbol{j}_2] = 0$, be these angular momenta and $\mathcal{H}_1$ and $\mathcal{H}_2$ the Hamiltonians of the orthogonal subsystems. As discussed in Appendix F.2.4 the angular momenta are conserved quantities if they commute with their Hamiltonian,

$$[\boldsymbol{j}_1, \mathcal{H}_1] = 0 \text{ and } [\boldsymbol{j}_2, \mathcal{H}_2] = 0. \tag{3.150}$$

When $\mathcal{H}_0 = \mathcal{H}_1 + \mathcal{H}_2$ is the Hamiltonian of the combined system, it follows from the commutation relations (3.150) that also the total angular momentum $\mathbf{J} = \boldsymbol{j}_1 + \boldsymbol{j}_2$ is a conserved quantity,

$$[\mathbf{J}, \mathcal{H}_0] = 0. \tag{3.151}$$

This is no surprise: given the homogeneity and isotropy of free space, the linear and angular momenta of a closed mechanical system are always conserved. Importantly, note that $\boldsymbol{j}_1$ and $\boldsymbol{j}_2$ commute with each other, $[\boldsymbol{j}_1, \boldsymbol{j}_2] = 0$, but *not* with $\mathbf{J}$ (only the components along the quantization axis do). This shows that the three conserved quantities $\boldsymbol{j}_1$, $\boldsymbol{j}_2$ and $\mathbf{J}$ do *not* share a joint basis. For this reason the properties of $\boldsymbol{j}_1$ and $\boldsymbol{j}_2$ are most conveniently evaluated in the uncoupled basis, $\{|j_1 m_1; j_2 m_2\rangle\}$, whereas the coupled basis, $\{|j_1 j_2 JM\rangle\}$, is the preferred basis to analyze $\mathbf{J}$.

In typical situations, the simultaneous conservation of $\boldsymbol{j}_1$, $\boldsymbol{j}_2$ and $\mathbf{J}$ is broken when a so-called *coupling term*, $\mathcal{H}'$, enters the Hamiltonian

$$\mathcal{H} = \mathcal{H}_1 + \mathcal{H}_2 + \mathcal{H}'. \tag{3.152}$$

Let us analyze two examples. First we consider a case of *mutual* coupling,

$$\mathcal{H}' = \alpha \boldsymbol{j}_1 \cdot \boldsymbol{j}_2. \tag{3.153}$$

Being mutual, this coupling is *internal* and the system remains mechanically closed, so we know that $\mathbf{J}$ has to remain conserved. This is confirmed by the commutation relation $[\mathbf{J}, \mathcal{H}] = 0$, which is valid because $\mathbf{J}$ commutes with $\boldsymbol{j}_1 \cdot \boldsymbol{j}_2$, although, individually, $\boldsymbol{j}_1$ and $\boldsymbol{j}_2$ do not commute with $\boldsymbol{j}_1 \cdot \boldsymbol{j}_2$ (see Problem 4.7). This shows that $\boldsymbol{j}_1$ and $\boldsymbol{j}_2$ are no longer conserved, although the magnitude of these vectors (i.e., the quantum numbers j_1 and j_2) as well as their vector sum, $\mathbf{J}$, still are. This is expressed by the commutation relations

$$[j_i^2, j_1 \cdot j_2] = 0, \;\; [J_z, j_1 \cdot j_2] = 0, \;\; [\mathbf{J}^2, j_1 \cdot j_2] = 0 \text{ and } [j_i^2, \mathbf{J}^2] = 0, \tag{3.154}$$

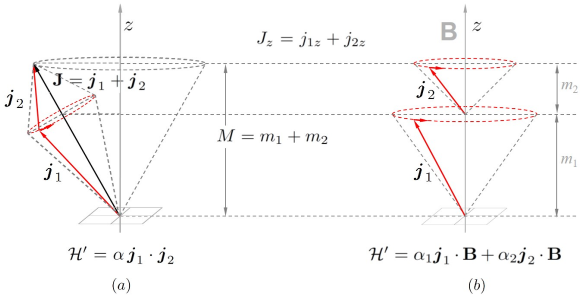

Figure 3.5: Two examples of coupling of the angular momenta $\boldsymbol{j}_1$ and $\boldsymbol{j}_2$: (a) In the presence of the *mutual coupling mechanism* $\mathcal{H}' = \alpha\,\boldsymbol{j}_1 \cdot \boldsymbol{j}_2$, the angular momenta $\boldsymbol{j}_1$ and $\boldsymbol{j}_2$ precess about $\mathbf{J} = \boldsymbol{j}_1 + \boldsymbol{j}_2$. This gives rise to time-varying projections of $\boldsymbol{j}_1$ and $\boldsymbol{j}_2$ on the z-axis but $\mathbf{J}$ as well as the projections $\boldsymbol{j}_1 \cdot \mathbf{J}$ and $\boldsymbol{j}_2 \cdot \mathbf{J}$ remain conserved. In other words: j_1, j_2, J and M are good quantum numbers; (b) In the presence of *coupling to an external field in the z-direction*, $\mathcal{H}' = \alpha_1 \boldsymbol{j}_1 \cdot \mathbf{B} + \alpha_2 \boldsymbol{j}_2 \cdot \mathbf{B}$, the angular momenta $\boldsymbol{j}_1$ and $\boldsymbol{j}_2$ precess individually about the z-axis. Since the projections j_{1z} and j_{2z} remain conserved, j_1, m_1, j_2 and m_2 are good quantum numbers. Note that only *in the absence of any coupling* the three angular momenta $\boldsymbol{j}_1$, $\boldsymbol{j}_2$ and $\mathbf{J}$ are simultaneously conserved.

with $i \in \{1, 2\}$ (see Problems 4.3-4.6). Hence this coupling is best analyzed in the coupled basis, $\{|j_1 j_2 JM\rangle\}$. The behavior of the physical system is sketched in Fig. 3.5*a*: $\boldsymbol{j}_1$ and $\boldsymbol{j}_2$ precess about $\mathbf{J}$. In the semi-classical picture, the angle between $\boldsymbol{j}_1$ and $\boldsymbol{j}_2$ is conserved because the system cannot lower its interaction energy (hamiltonian evolution is dissipation free).

As a second example we consider a coupling term of the Zeeman type (see Section 4.3.3),

$$\mathcal{H}' = \alpha_1 \boldsymbol{j}_1 \cdot \mathbf{B} + \alpha_2 \boldsymbol{j}_2 \cdot \mathbf{B}. \tag{3.155}$$

In this case the angular momenta are individually coupled to the *external* magnetic field $\mathbf{B}$. The external field breaks the spherical symmetry of free space and by choosing the quantization axis along $\mathbf{B}$ we find that only the z components of $\boldsymbol{j}_1$ and $\boldsymbol{j}_2$ remain conserved,

$$[j_{1z}, \mathcal{H}] = 0 \text{ and } [j_{2z}, \mathcal{H}] = 0. \tag{3.156}$$

The physical system is sketched in Fig. 3.5*b*: the angular momenta $\boldsymbol{j}_1$ and $\boldsymbol{j}_2$ precess individually about the $\mathbf{B}$ field. Since $\boldsymbol{j}_1$ and $\boldsymbol{j}_2$ are no longer conserved also $\mathbf{J}$ is no longer conserved. In this case only the magnitude of the vectors $\boldsymbol{j}_1$ and $\boldsymbol{j}_2$ (i.e., the quantum numbers j_1 and j_2) as well as their projections (i.e., the quantum numbers m_1 and m_2) are constants of the motion. This behavior is best captured by the uncoupled basis, $\{|j_1 m_1; j_2 m_2\rangle\}$.

Summary

In the absence of any coupling all three angular momenta $\boldsymbol{j}_1$, $\boldsymbol{j}_2$ and $\mathbf{J}$ are simultaneously conserved; i.e., j_1, m_1, j_2, m_2 as well as J and M are good quantum numbers - whatever the quantization axis. In the presence of pure $\boldsymbol{j}_1 \cdot \boldsymbol{j}_2$ coupling both $\mathbf{J}$ and J_z are conserved; i.e., J and M are good quantum numbers - whatever the quantization axis. In the presence of pure Zeeman coupling only j_{1z}, j_{2z} and J_z are conserved; i.e., m_1, m_2 and $M = m_1 + m_2$ are good quantum numbers with respect to the direction of the symmetry-breaking field.

Coupling of the J levels

Note that in both of the above coupling cases the commutation relation $[J_z, \mathcal{H}]$ holds. So, also in the simultaneous presence of both couplings,

$$\mathcal{H}' = \alpha_1 \boldsymbol{j}_1 \cdot \mathbf{B} + \alpha_2 \boldsymbol{j}_2 \cdot \mathbf{B} + \alpha\,\boldsymbol{j}_1 \cdot \boldsymbol{j}_2, \tag{3.157}$$

the operator $J_z = j_{1z} + j_{2z}$ corresponds to a conserved quantity; i.e., M is a good quantum number. For $B \to 0$ the eigenstates are given by the coupled representation, $\{|j_1 j_2 JM\rangle\}$, whereas for $B \to \infty$ this becomes the uncoupled representation, $\{|j_1 m_1; j_2 m_2\rangle\}$, with $M = m_1 + m_2$. For intermediate fields the basis can be denoted by $\{|j_1 j_2 m\rangle\}$, where $\mathcal{H}'|j_1 j_2 m\rangle = \varepsilon_{jm}(B)|j_1 j_2 m\rangle$ and the definition of $|j_1 j_2 m\rangle$ depends on the field. Decomposing $|j_1 j_2 m\rangle$ with respect to the coupled basis we find

$$|j_1 j_2 m\rangle = \sum_{J,M} |j_1 j_2 JM\rangle\langle j_1 j_2 JM|j_1 j_2 m\rangle = \sum_J \alpha_J(B)\, |j_1 j_2 Jm\rangle, \tag{3.158}$$

where the $\alpha_J(B) = \langle j_1 j_2 JM|j_1 j_2 m\rangle$ are field-dependent coefficients. This shows that for intermediate fields $|j_1 j_2 jm\rangle$ can be written as a linear combination of all coupled states $|j_1 j_2 JM\rangle$ for which $M = m$. This is called mixing of the J levels by the Zeeman coupling.

Problem 3.18. Let us denote two angular momenta by $\boldsymbol{j}_1 = \mathbf{L}$ and $\boldsymbol{j}_2 = \mathbf{S}$, and their vector sum by $\mathbf{J} = \mathbf{L} + \mathbf{S}$. Derive the following three inner product rules,

$$\mathbf{L} \cdot \mathbf{S} = L_x S_x + L_y S_y + L_z S_z \tag{3.159a}$$

$$\mathbf{L} \cdot \mathbf{S} = L_z S_z + \tfrac{1}{2}\left(L_+ S_- + L_- S_+\right) \tag{3.159b}$$

$$\mathbf{L} \cdot \mathbf{S} = \tfrac{1}{2}(\mathbf{J}^2 - \mathbf{L}^2 - \mathbf{S}^2). \tag{3.159c}$$

Solution. Rule (a) is simply the definition of the inner product in cartesian coordinates. Using the definitions for the shift operators we have

$$L_+ S_- = (L_x + iL_y)(S_x - iS_y) = L_x S_x + L_y S_y + i\,(L_y S_x - L_x S_y)$$
$$L_- S_+ = (L_x - iL_y)(S_x + iS_y) = L_x S_x + L_y S_y - i\,(L_y S_x - L_x S_y)\,.$$

Adding these expressions and using rule (a) we obtain after rearrangement of terms rule (b). Note that the $L_z S_z$ operator as well as the operators $L_+ S_-$ and $L_- S_+$ conserve the total angular momentum along the quantization axis $m_j = m_l + m_s$. Rule (c) follows straightforwardly from the inner product $\mathbf{J}^2 = (\mathbf{L} + \mathbf{S})^2 = \mathbf{L}^2 + \mathbf{S}^2 + 2\mathbf{L} \cdot \mathbf{S}$ because $\mathbf{L}$ and $\mathbf{S}$ commute (they act in independent sectors of Hilbert space). □

3.7 Addition of three angular momenta

In the case of three angular momenta, $\boldsymbol{j}_1$, $\boldsymbol{j}_2$ and $\boldsymbol{j}_3$, acting in three *independent* subspaces of the Hilbert space, the total angular momentum is given by

$$\mathbf{J} = \boldsymbol{j}_1 + \boldsymbol{j}_2 + \boldsymbol{j}_3.$$

In this case there is no unique addition procedure. Defining $\boldsymbol{j}_{12} = \boldsymbol{j}_1 + \boldsymbol{j}_2$, $\boldsymbol{j}_{23} = \boldsymbol{j}_2 + \boldsymbol{j}_3$ and $\boldsymbol{j}_{13} = \boldsymbol{j}_1 + \boldsymbol{j}_3$ we have

$$|(j_{12} j_3) JM\rangle = \sum_{m_{12}=-j_{12}}^{j_{12}} \sum_{m_3=-j_3}^{j_3} |j_{12} m_{12}; j_3 m_3\rangle\langle j_{12} m_{12}; j_3 m_3|(j_{12} j_3) JM\rangle, \tag{3.160a}$$

where $|j_{12} m_{12}; j_3 m_3\rangle \equiv |(j_1 j_2) j_{12} m_{12}\rangle \otimes |j_3 m_3\rangle$ and

$$|j_{12} m_{12}\rangle = \sum_{m_1=-j_1}^{j_1} \sum_{m_2=-j_2}^{j_2} |j_1 m_1; j_2 m_2\rangle\langle j_1 m_1; j_2 m_2|j_{12} m_{12}\rangle. \tag{3.160b}$$

Substituting (3.160b) into (3.160a) we obtain an expression for $|(j_{12} j_3) JM\rangle$. Likewise we obtain an expression for $(j_1 j_{23}) J'M'\rangle$.

$$|(j_{12} j_3) JM\rangle = \sum_{m_1,m_2,m_3,m_{12}} |j_1 m_1; j_2 m_2; j_3 m_3\rangle\langle j_1 m_1; j_2 m_2|j_{12} m_{12}\rangle\langle j_{12} m_{12}; j_3 m_3|(j_{12} j_3) JM\rangle, \tag{3.161a}$$

$$|(j_1 j_{23}) J'M'\rangle = \sum_{m_1,m_2,m_3,m_{23}} |j_1 m_1; j_2 m_2; j_3 m_3\rangle\langle j_2 m_2; j_3 m_3|j_{23} m_{23}\rangle\langle j_1 m_1; j_{23} m_{23}|(j_1 j_{23}) J'M'\rangle, \tag{3.161b}$$

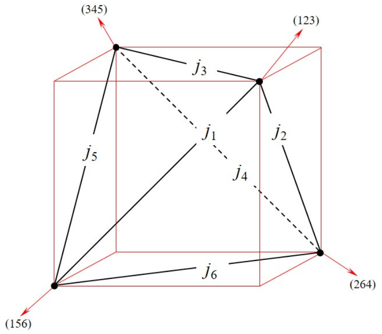

Figure 3.6: Graphical representation of Wigner 6-j symbols in the form of a tetrahedron. Each corner vertex represents one of four $3j$ symbols. The $6j$ symbols are invariant under all symmetry operations, rotations and/or reflections, of the tetrahedral group (resulting in all 4! permutations of the corner points).

where $|j_1m_1; j_2m_2; j_3m_3\rangle \equiv |j_1m_1\rangle \otimes |j_2m_2\rangle \otimes |j_3m_3\rangle$. Projection of the coupling scheme (3.161b) onto (3.161a) results in recoupling coefficient,

$$\langle (j_{12}j_3)JM|(j_1j_{23})J'M'\rangle = \sum_{\substack{m_1,m_2,m_3\\ m_{12},m_{23}}} \langle j_1m_1; j_2m_2|j_{12}m_{12}\rangle \langle j_{12}m_{12}; j_3m_3|(j_{12}j_3)JM\rangle$$
$$\langle j_2m_2; j_3m_3|j_{23}m_{23}\rangle \langle j_1m_1; j_{23}m_{23}|(j_1j_{23})J'M'\rangle. \quad (3.162)$$

Note that the value of the recoupling coefficient is independent of M. So, aiming for maximum symmetry we may sum over M provided we divide by $2J+1$ to correct for double counting. After turning to $3j$ symbols the recoupling coefficient takes the form

$$\langle (j_{12}j_3)JM|(j_1j_{23})J'M'\rangle = \sum_{\substack{m_1,m_2,m_3\\ m_{12},m_{23},M}} (-1)^{\varphi} \sqrt{(2j_{12}+1)(2j_{23}+1)(2J'+1)/(2J+1)}$$
$$\times \begin{pmatrix} j_1 & j_2 & j_{12} \\ m_1 & m_2 & -m_{12} \end{pmatrix} \begin{pmatrix} j_{12} & j_3 & J \\ m_{12} & m_3 & -M \end{pmatrix} \begin{pmatrix} j_2 & j_3 & j_{23} \\ m_2 & m_3 & -m_{23} \end{pmatrix} \begin{pmatrix} j_1 & j_{23} & J' \\ m_1 & m_{23} & -M' \end{pmatrix}, \quad (3.163)$$

where

$$\varphi = j_1 - j_2 + m_{12} + j_{12} - j_3 + M + j_2 - j_3 + m_{23} + j_1 - j_{23} + M'. \quad (3.164)$$

3.7.1 Wigner $6j$ symbols

In view of the CGC selection rules the coupling coefficient (3.163) vanishes unless $m_{12} = m_1 + m_2$, $m_{23} = m_2 + m_3$, $M = m_{12} + m_3 = m_1 + m_2 + m_3 = m_1 + m_{23} = M'$. The latter condition can only be satisfied for all values of M if also $J = J'$. Wigner expressed this in the form

$$\langle (j_{12}j_3)J'M'|(j_1j_{23})JM\rangle = (-1)^{j_1+j_2+j_3+J} \sqrt{(2j_{12}+1)(2j_{23}+1)} \begin{Bmatrix} j_1 & j_2 & j_{12} \\ j_3 & J & j_{23} \end{Bmatrix} \delta_{J,J'} \delta_{M,M'}, \quad (3.165)$$

which includes a so-called $6j$ symbol. Note that $j_1 + j_2 + j_3 + J$ is always an integer. Like the $3j$ symbols also the Wigner $6j$ symbols offer optimized symmetry rules. By comparing Eq. (3.165) with Eq. (3.163) the $6j$ symbol can be expressed in the following form - see Problem 3.19,

$$\begin{Bmatrix} j_1 & j_2 & j_3 \\ j_4 & j_5 & j_6 \end{Bmatrix} = \sum_{\substack{m_1,m_2,m_3\\ m_4,m_5,m_6}} (-1)^{\sigma} \begin{pmatrix} j_1 & j_2 & j_3 \\ m_1 & m_2 & m_3 \end{pmatrix} \begin{pmatrix} j_1 & j_5 & j_6 \\ m_1 & m_5 & -m_6 \end{pmatrix} \begin{pmatrix} j_2 & j_6 & j_4 \\ m_2 & m_6 & -m_4 \end{pmatrix} \begin{pmatrix} j_3 & j_4 & j_5 \\ m_3 & m_4 & -m_5 \end{pmatrix}, \quad (3.166)$$

where $\sigma = j_4 + j_5 + j_6 + m_4 + m_5 + m_6$. A graphical representation is given in Fig. 3.6.

Problem 3.19. Derive Eq. (3.166).

Solution. We start from Eq. (3.165). Comparing this expression with Eq. (3.163) we obtain an expression for the $6j$symbol. To emphasize the symmetry we relabel the following quantum numbers: $(j_3, m_3) \to (j_4, m_4)$, $(j_{12}, m_{12}) \to (j_3, m_3)$, $(J, M) \to (j_5, m_5)$, $(j_{23}, m_{23}) \to (j_6, m_6)$. In this way we obtain

$$\begin{Bmatrix} j_1 \, j_2 \, j_3 \\ j_4 \, j_5 \, j_6 \end{Bmatrix} = \sum_{\substack{m_1, m_2, m_3 \\ m_4, m_5, m_6}} (-1)^{\varphi_1} \begin{pmatrix} j_1 & j_2 & j_3 \\ m_1 & m_2 & -m_3 \end{pmatrix} \begin{pmatrix} j_3 & j_4 & j_5 \\ m_3 & m_4 & -m_5 \end{pmatrix} \begin{pmatrix} j_2 & j_4 & j_6 \\ m_2 & m_4 & -m_6 \end{pmatrix} \begin{pmatrix} j_1 & j_6 & j_5 \\ m_1 & m_6 & -m_5 \end{pmatrix},$$

where $\varphi_1 = 3j_1 + j_2 + j_3 - j_4 + j_5 - j_6 + m_3 + 2m_5 + m_6$ (note that $j_1 + j_2 + j_4 + j_5 \in \mathbb{Z}$). To arrive at the full symmetry of the $6j$ symbol we reorder the $3j$ symbols to match the arrangement indicated on the tetrahedron in Fig. 3.6. For this purpose we swap the last two columns in both the third and the fourth $3j$ symbol and adapt the phase accordingly,

$$\begin{Bmatrix} j_1 \, j_2 \, j_3 \\ j_4 \, j_5 \, j_6 \end{Bmatrix} = \sum_{\substack{m_1, m_2, m_3 \\ m_4, m_5, m_6}} (-1)^{\varphi_2} \begin{pmatrix} j_1 & j_2 & j_3 \\ m_1 & m_2 & -m_3 \end{pmatrix} \begin{pmatrix} j_3 & j_4 & j_5 \\ m_3 & m_4 & -m_5 \end{pmatrix} \begin{pmatrix} j_2 & j_6 & j_4 \\ m_2 & -m_6 & m_4 \end{pmatrix} \begin{pmatrix} j_1 & j_5 & j_6 \\ m_1 & -m_5 & m_6 \end{pmatrix},$$

with $\varphi_2 = 4j_1 + 2j_2 + j_3 + 2j_5 + j_6 + m_3 + 2m_5 + m_6$. Next we can replace the summations over m_3, m_4, m_5 and m_6 by summations over $-m_3$, $-m_4$, $-m_5$ and $-m_6$ adapting the phase accordingly,

$$\begin{Bmatrix} j_1 \, j_2 \, j_3 \\ j_4 \, j_5 \, j_6 \end{Bmatrix} = \sum_{\substack{m_1, m_2, m_3 \\ m_4, m_5, m_6}} (-1)^{\varphi_3} \begin{pmatrix} j_1 & j_2 & j_3 \\ m_1 & m_2 & m_3 \end{pmatrix} \begin{pmatrix} j_3 & j_4 & j_5 \\ -m_3 & -m_4 & m_5 \end{pmatrix} \begin{pmatrix} j_2 & j_6 & j_4 \\ m_2 & m_6 & -m_4 \end{pmatrix} \begin{pmatrix} j_1 & j_5 & j_6 \\ m_1 & m_5 & -m_6 \end{pmatrix},$$

with $\varphi_3 = 2j_1 - j_3 + 2j_5 + j_6 - m_3 - 2m_5 - m_6$ (since $2j_1 + 2j_2 + 2j_3$ is always even). To arrive at Eq. (3.166) we apply the projection rule to the second $3j$ symbol and obtain for the exponent of the phase $\varphi_4 = j_4 + j_5 + j_6 + m_4 + m_5 + m_6 + 2j_1 + 2j_5 - m_3 - m_4 - 3m_5 - 2m_6$. Since $2j_i \pm 2m_i$ is always *even* and $(-1)^{2m_i} = (-1)^{-2m_i}$ for $i \in \{1, 2, 3, 4, 5, 6\}$ as well as the projection rules $m_3 + m_4 - m_5 = 0$ and $m_1 + m_5 - m_6 = 0$ we have

$$(-1)^{\varphi_4} = (-1)^{\sigma - 2m_1 - m_3 - m_4 - m_5 + 2m_6} = (-1)^{\sigma - 2m_1 - 2m_5 + 2m_6} = (-1)^{\sigma},$$

where $\sigma = j_4 + j_5 + j_6 + m_4 + m_5 + m_6$. □

3.7.1.1 Properties of $6j$ symbols

The $3j$ symbols inherit their *properties* from the CGCs. So, the $3j$ symbols are *zero unless*

1. The *triangle inequality* holds for all combinations $\Delta(j_k j_l j_m) > 0$ for $k, l, m \in \{1, \cdots 6\}$
2. The *sum* of the angular momenta is *integral*, $j_k + j_l + j_m \in \mathbb{Z}$ for $k, l, m \in \{1, \cdots 6\}$

Symmetry properties: $6j$ symbols *are invariant* under all symmetry operations of the tetrahedral group - see Fig. 3.6. These result in invariance under

1. *permutations* of the columns; e.g.,

$$\begin{Bmatrix} j_1 \, j_2 \, j_3 \\ j_4 \, j_5 \, j_6 \end{Bmatrix} = \begin{Bmatrix} j_2 \, j_1 \, j_3 \\ j_5 \, j_4 \, j_6 \end{Bmatrix}$$

2. *simultaneous exchange* of *two* opposing elements of the rows; e.g.,

$$\begin{Bmatrix} j_1 \, j_2 \, j_3 \\ j_4 \, j_5 \, j_6 \end{Bmatrix} = \begin{Bmatrix} j_4 \, j_5 \, j_3 \\ j_1 \, j_2 \, j_6 \end{Bmatrix}.$$

3.8 Angular momentum and infinitesimal rotations

3.8.1 Rotations versus unitary transformations

In Section 3.1.1 we found that the decomposition of the angular momentum operator $\mathbf{J}$ maps uniquely onto that of the radius vector $\mathbf{r}$. To further explore the properties of $\mathbf{J}$ we ask ourselves how this vector operator transforms into an operator $\mathbf{J}'$ by changing from one quantization axis to another. Such a change can be implemented by a *proper* rotation of the coordinate system about the origin. This is a rotation in which the handedness of the coordinate system is conserved.[1] A rotation of the coordinate system is called a *passive* rotation to distinguish it from *physical* rotations, in which the physical system is rotated (i.e., the "contours" of the wavefunction) and the coordinate system is fixed.

So let us consider the proper rotation R by which the right-handed cartesian coordinate system $\mathcal{S}$ transforms into $\mathcal{S}'$; i.e., the direction $\hat{\mathbf{r}} = (x, y, z)$ of a vector with respect to $\mathcal{S}$ changes into $\hat{\mathbf{r}}' = (x', y', z')$ with respect to $\mathcal{S}'$ under conservation of the handedness of the coordinate system,

$$\hat{\mathbf{r}}' = R\,\hat{\mathbf{r}}. \tag{3.167}$$

This transformation holds, in particular, for the quantization axis. Equivalently, we can fix the coordinate system $\mathcal{S}$ and apply the inverse rotation to $\mathbf{J}$,

$$\mathbf{J}' = R^{-1}\mathbf{J}. \tag{3.168}$$

The existence of the inverse is evident from a physical point of view. Mathematically, it follows from the nonzero determinant ($\det R = 1$ for proper rotations) - see Appendix M. Comparing the two approaches we find the relation

$$\mathbf{J} \cdot \hat{\mathbf{r}}' = \mathbf{J}' \cdot \hat{\mathbf{r}}. \tag{3.169}$$

Before we analyze the equality of these two inner products we discuss the effect of a change of quantization axis on the angular momentum states. The new quantization axis comes with a new set of basis states, $\{|j, m\rangle'\}$. These are the joint eigenstates of $\mathbf{J}'^2$ and J_z' and are related to the original basis of the operators $\mathbf{J}^2$ and J_z, $\{|j, m\rangle\}$, by a *norm-conserving* basis transformation,

$$|\chi\rangle' = \underline{u}|\chi\rangle. \tag{3.170}$$

Here $|\chi\rangle$ is an arbitrary angular momentum state within the invariant subspace V^{2j+1} of the operators $\mathbf{J}'$ and $\mathbf{J}$. The transformation $\underline{u}$ has to be norm conserving because $|\chi\rangle$ and $|\chi\rangle'$ represent the *same* state with respect to two *different* bases,

$$\langle\chi|\chi\rangle = \langle\chi|\chi\rangle' = \langle\chi|\underline{u}^{\dagger}\underline{u}|\chi\rangle \to \underline{u}^{\dagger}\underline{u} = \mathbb{1}. \tag{3.171}$$

This identity shows that the transformation must be unitary, $\underline{u}^{\dagger} = \underline{u}^{-1}$, which implies that the inverse transformation is given by

$$|\chi\rangle = \underline{u}^{\dagger}|\chi\rangle'. \tag{3.172}$$

Furthermore, as $|\chi\rangle$ and $|\chi\rangle'$ represent the *same* state (the rotation is passive) we require

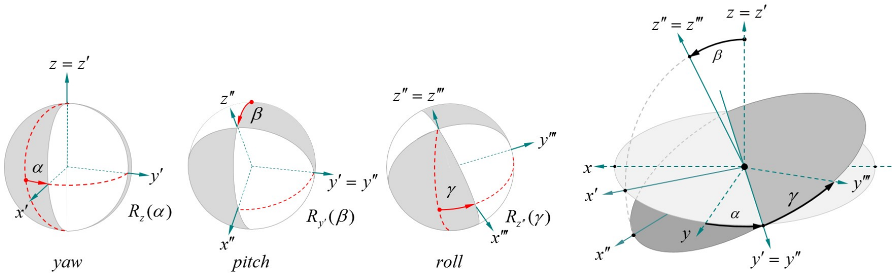
$$\langle\chi|\mathbf{J}'|\chi\rangle' = \langle\chi|\mathbf{J}|\chi\rangle. \tag{3.173}$$

In other words, we require that the expectation value of the operator be invariant under rotation of the coordinate system. In particular, this should hold for observables. Substituting Eq. (3.172) in the r.h.s. of Eq. (3.173) we obtain

$$\langle\chi|\mathbf{J}'|\chi\rangle' = \langle\chi|\underline{u}\mathbf{J}\underline{u}^{\dagger}|\chi\rangle'. \tag{3.174}$$

---

[1] A proper rotation, R, is an orthogonal transformation ($R^{-1} = R^T$) with unit determinant ($\det R = 1$) - see Appendix M.



(*b*) (*a*)

Figure 3.7: (a) an arbitrary *passive* rotation can be decomposed into three subsequent positive rotations of a coordinate system over the Euler angles α, β and γ called *yaw*, *pitch* and *roll* in aviation; (b) the same three Euler rotations shown for a coordinate system attached to an *imaginary* ball for clarity of illustration. All figures show the orientation *after* rotation over the angle indicated by the arrow. The right-handedness of coordinate system and positive sense of rotation, in combination with the $z-y-z$ rotation sequence for the Euler angles correspond to the convention of Rose [94] (beware of other conventions in the literature).

As this expression holds for arbitrary $|\chi\rangle$ we find that under the rotation (3.167) the transformation of the operator $\mathbf{J}$ involves the same unitary operator as used for the states $|\chi\rangle$,

$$\mathbf{J}' = \underline{u}\,\mathbf{J}\,\underline{u}^{\dagger}. \tag{3.175}$$

We now return to the two inner products of Eq. (3.169). Substituting Eq. (3.167) into the l.h.s. of Eq. (3.169) and Eq. (3.175) into the r.h.s., we arrive at an expression relating the rotation R of the cartesian coordinate system $\mathcal{S}$ (in real space) to the corresponding unitary transformation $\underline{u}$ (in Hilbert space),

$$\mathbf{J}\cdot R\,\hat{\mathbf{r}} = \underline{u}\,\mathbf{J}\,\underline{u}^{\dagger}\cdot\hat{\mathbf{r}}. \tag{3.176}$$

For two subsequent rotations this expression becomes

$$\mathbf{J}\cdot R_2(R_1\,\hat{\mathbf{r}}) = \underline{u}_2(\underline{u}_1\,\mathbf{J}\,\underline{u}_1^{\dagger})\underline{u}_2^{\dagger}\cdot\hat{\mathbf{r}}. \tag{3.177}$$

So, once we have an expression for R (see Section 3.8.2), Eqs. (3.176) and (3.177) can serve to determine $\underline{u}$. This is the subject of Section 3.8.3.

Transformation of the cartesian components

Combining Eqs. (3.175) and (3.168) we obtain for the *cartesian* components of $\mathbf{J}'$

$$J'_j = \underline{u}\,J_j\,\underline{u}^{\dagger} = \sum_i [R^{-1}]_{ji} J_i = \sum_i [R]_{ij} J_i, \tag{3.178}$$

with $i, j \in \{x, y, z\}$, where we used the property (M.13) of orthogonal matrices, $R^{-1} = R^T$. Eq. (3.178) shows that the components of $\mathbf{J}'$ (i.e., with respect to the rotated frame) can be expressed in two ways:

- as a unitary transformation of the cartesian components of $\mathbf{J}$ (in Hilbert space)
- as a decomposition in terms of the cartesian components of $\mathbf{J}$ (in real space).

In the latter case the coefficients of the decomposition are matrix elements of the rotation matrix R. In Section 3.9.5 we shall present a similar transformation for the *spherical* components.

3.8.2 Rotation in the euclidean space - Euler angles

First we discuss rotations of the coordinate system about the origin as expressed by Eq. (3.167). In matrix notation this passive rotation takes the form

$$\begin{pmatrix} x' \\ y' \\ z' \end{pmatrix} = R \begin{pmatrix} x \\ y \\ z \end{pmatrix}, \tag{3.179}$$

where x, y, z and x', y', z' are the cartesian coordinates of the position vector before and after the transformation, respectively. According to the *Euler rotation theorem* any proper rotation of the coordinate system $\mathcal{S}$ can be decomposed into three subsequent proper rotations about specified angles and axes, as illustrated in Fig. 3.7. Throughout these lectures we adopt the $z-y-z$ rotation sequence convention of Rose [94] (see Fig. 3.7). First, a *positive* rotation $R_z(\alpha)$ of $\mathcal{S}$ to $\mathcal{S}'$ over the angle α about the *positive* z direction is given by[1]

$$R_z(\alpha) = \begin{pmatrix} \cos\alpha & \sin\alpha & 0 \\ -\sin\alpha & \cos\alpha & 0 \\ 0 & 0 & 1 \end{pmatrix}. \tag{3.180}$$

In aviation this rotation is called *yaw* and corresponds to a change of *heading*. Second, a positive rotation $R_{y'}(\beta)$ of $\mathcal{S}'$ to $\mathcal{S}''$ over the angle β about the y' axis (the y axis of $\mathcal{S}'$) is given by

$$R_{y'}(\beta) = \begin{pmatrix} \cos\beta & 0 & -\sin\beta \\ 0 & 1 & 0 \\ \sin\beta & 0 & \cos\beta \end{pmatrix}. \tag{3.181}$$

In aviation β is called the *pitch* angle. Finally, a rotation $R_{z''}(\gamma)$ of $\mathcal{S}''$ to $\mathcal{S}'''$ over the angle γ about the z'' axis (the z axis of $\mathcal{S}''$) is, analogously to $R_z(\alpha)$, given by

$$R_{z''}(\gamma) = \begin{pmatrix} \cos\gamma & \sin\gamma & 0 \\ -\sin\gamma & \cos\gamma & 0 \\ 0 & 0 & 1 \end{pmatrix}. \tag{3.182}$$

In aviation γ is called the *roll* angle. Note that $R_z(\alpha)$, $R_{y'}(\beta)$ and $R_{z''}(\gamma)$ are orthogonal matrices with determinant $+1$ (see Appendix M). Hence, in using the Euler angles, the rotations are specified with respect to the coordinate system fixed to an observer (the *pilot*) experiencing the rotations,

$$\hat{\mathbf{r}}' = R(\alpha,\beta,\gamma)\,\hat{\mathbf{r}} = R_{z''}(\gamma)R_{y'}(\beta)R_z(\alpha)\,\hat{\mathbf{r}}. \tag{3.183}$$

Evaluating the matrix product we find

$$R = \begin{pmatrix} -\sin\alpha\sin\gamma + \cos\alpha\cos\beta\cos\gamma & \cos\alpha\sin\gamma + \sin\alpha\cos\beta\cos\gamma & -\sin\beta\cos\gamma \\ -\sin\alpha\cos\gamma - \cos\alpha\cos\beta\sin\gamma & \cos\alpha\cos\gamma - \sin\alpha\cos\beta\sin\gamma & \sin\beta\sin\gamma \\ \cos\alpha\sin\beta & \sin\alpha\sin\beta & \cos\beta \end{pmatrix}. \tag{3.184}$$

Interestingly, a pure pitch β about the y' axis can be decomposed into three subsequent rotations in the laboratory-fixed frame $\mathcal{S}$ (see Fig. 3.8*a*),

$$R_{y'}(\beta) = R_z(\alpha)R_y(\beta)R_z(-\alpha). \tag{3.185}$$

---

[1] The sense of rotation in the direction $\hat{\mathbf{r}}$ is called positive if the *coordinate system*, $\mathcal{S}$, rotates in the same way as a right-handed screw advances in the direction $\hat{\mathbf{r}}$. By convention, the rotation angle *increases* for a *positive* rotation.

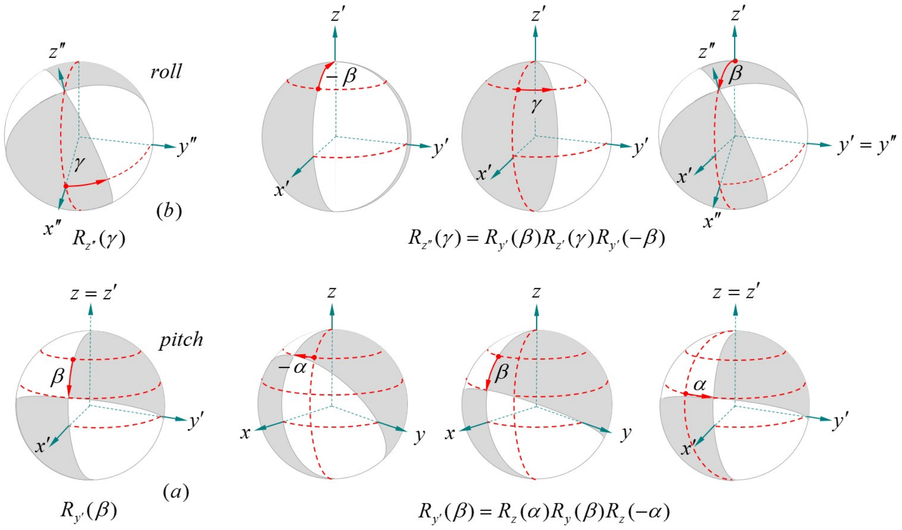


Figure 3.8: (a) the Euler rotation $R(\beta, y')$, i.e., pure *pitch* of the coordinate system $\mathcal{S}' = (x', y', z')$, is equivalent with three subsequent rotations of the frame $\mathcal{S} = (x, y, z)$; (b) the Euler rotation $R(\gamma, z'')$, i.e., pure *roll* of the coordinate system $\mathcal{S}'' = (x'', y'', z'')$, is equivalent with three subsequent rotations of the frame $\mathcal{S}'$. All figures show the orientation *after* rotation over the angle indicated by the arrow.

Likewise, a pure roll γ about the z'' axis can be decomposed into three subsequent rotations in the frame $\mathcal{S}'$ (see Fig. 3.8*b*),

$$R_{z''}(\gamma) = R_{y'}(\beta)R_{z'}(\gamma)R_{y'}(-\beta). \tag{3.186}$$

Substituting Eqs. (3.185) and (3.186) into Eq. (3.183) and using the commutation of $R_z(\alpha)$ and $R_{z'}(\gamma)$ (note that the z axis coincides with the z' axis) we find that the rotation R can also be realized by three subsequent rotations about laboratory-fixed axes,

$$R(\alpha, \beta, \gamma) = R_z(\alpha)R_y(\beta)R_z(\gamma). \tag{3.187}$$

Comparing Eqs. (3.187) and (3.183) we note that the same angles appear (α, β, γ) but *in reverse order.*

To conclude this section we point out that the set of all passive rotations in real space of a sphere about its center constitutes a group. If the general element of this group is given by $R(\alpha, \beta, \gamma)$, we find that $R(-\gamma, -\beta, -\alpha)$ is its inverse and $R(0, 0, 0)$ is the unit element. Furthermore, the set is closed under the group operation and successive operations are associative. This group is called the special orthogonal group SO(3); i.e., the group of all orthogonal coordinate transformations with determinant +1 in the three-dimensional real space.

3.8.3 Unitary transformation in Hilbert space for the case $s = 1/2$

Let us now leave real space and turn to the unitary transformations (3.170) and (3.175) in Hilbert space corresponding to the rotations R (the z axis being the quantization axis). In view of the special importance of two-level systems we demonstrate this for the case $s = \frac{1}{2}$. In Section 3.9.1 our findings will be generalized to the case of arbitrary angular momentum. For $s = \frac{1}{2}$ Eq. (3.176) can be written as a transformation of the Pauli matrices,

$$\boldsymbol{\sigma}\cdot R\,\hat{\mathbf{r}} = \underline{u}\,\boldsymbol{\sigma}\,\underline{u}^{\dagger}\cdot\hat{\mathbf{r}}. \tag{3.188}$$

To start the discussion we point out that the most general unitary 2 × 2 matrix is of the form (see Problem 3.20)

$$\underline{u} \equiv \sqrt{\Delta}\, U = \pm\sqrt{\Delta} \begin{pmatrix} a & b \\ -b^* & a^* \end{pmatrix}, \tag{3.189}$$

where $aa^* + bb^* = 1$ and $\Delta \equiv \det \underline{u}$ can be expressed in the form of a phase factor ($\Delta = e^{i\xi}$). The matrix U, with $\det U = 1$, is called the *special unitary matrix.* It is fully defined by the parameters a and b (*Cayley-Klein* parameters). Substituting Eq. (3.189) into the r.h.s. of Eq. (3.188) we obtain an expression for the most general unitary transformation of $\sigma_r = \boldsymbol{\sigma} \cdot \hat{\mathbf{r}}$,

$$\underline{u}\, \boldsymbol{\sigma}\, \underline{u}^\dagger \cdot \hat{\mathbf{r}} = \begin{pmatrix} A_x x + A_y y + A_z z & B_x x + B_y y + B_z z \\ (B_x x + B_y y + B_z z)^* & -(A_x x + A_y y + A_z z) \end{pmatrix}, \tag{3.190}$$

where the coefficients A_i and B_i, with $i \in \{x, y, z\}$, are defined in terms of the matrix elements a and b by the following fundamental expressions

$$\begin{array}{lll} A_x = ab^* + ba^* & A_y = -i\,(ab^* - ba^*) & A_z = aa^* - bb^* \\ B_x = a^2 - b^2 & B_y = -i\left(a^2 + b^2\right) & B_z = -2ab. \end{array} \tag{3.191}$$

Note from Eq. (3.190) that the phase factor $\Delta = e^{i\xi}$ has dropped out of the analysis. This means that we are free to choose Δ. The obvious choice is $\Delta = 1$, which means that the analysis can be restricted to the special unitary matrix U.

To determine the $U_z(\alpha)$ corresponding to the Euler rotation $R_z(\alpha)$ we substitute Eq. (3.180) into the matrix equation (3.188) and obtain after some matrix manipulation

$$\boldsymbol{\sigma} \cdot R_z(\alpha)\hat{\mathbf{r}} = \begin{pmatrix} z & e^{i\alpha}x - ie^{i\alpha}y \\ e^{-i\alpha}x + ie^{-i\alpha}y & -z \end{pmatrix}. \tag{3.192}$$

It is instructive to compare this expression with the non-rotated form of σ_r as given in Eq. (3.48). Equating the matrices (3.192) and (3.190) gives $A_x = A_y = 0, A_z = 1$ en $B_x = e^{i\alpha}, B_y = -ie^{i\alpha}, B_z = 0$. Further comparison with the fundamental expression for A_z in (3.191) yields $A_z = aa^* - bb^* = 1$. In combination with the property $aa^* + bb^* = 1$ we find $b = 0$. Substituting this result into the fundamental expression for B_x we find $B_x = a^2 = e^{i\alpha}$. Thus, we arrive at $a = e^{i\alpha/2}$ and obtain for the special unitary matrix corresponding to $R_z(\alpha)$

$$U_z(\alpha) = \pm \begin{pmatrix} e^{i\alpha/2} & 0 \\ 0 & e^{-i\alpha/2} \end{pmatrix}. \tag{3.193}$$

Note that the positive and negative solution are connected by a rotation over 2π,

$$-\,U_z(\alpha) = U_z(2\pi)U_z(\alpha) = U_z(\alpha + 2\pi) = U_{-z}(-\alpha - 2\pi). \tag{3.194}$$

Apparently, after rotating over 2π we evolve from one solution to the other.

Likewise, for the Euler rotation $R_y(\beta)$ we obtain $A_x = \sin\beta$, $A_y = 0$, $A_z = \cos\beta$ and $B_x = \cos\beta$, $B_y = -i$, $B_z = -\sin\beta$. Comparing the result for B_x and B_y with the fundamental expressions in (3.191) we find $\cos\beta = 2a^2 - 1$, which implies $a = \cos(\beta/2)$. The comparison of A_x and A_y with the fundamental expressions in (3.191) yields $\sin\beta = 2ab^*$, which after the substitution of the result for a leads to $b = \sin(\beta/2)$. Thus we obtain for the special unitary matrix corresponding to $R_y(\beta)$

$$U_y(\beta) = \pm \begin{pmatrix} \cos(\beta/2) & \sin(\beta/2) \\ -\sin(\beta/2) & \cos(\beta/2) \end{pmatrix}, \tag{3.195}$$

which satisfies the same rotation property as Eq. (3.194),

$$-\,U_y(\beta) = U_y(2\pi)U(2\pi) = U_y(\beta + 2\pi) = U_{-y}(-\beta - 2\pi). \tag{3.196}$$

Next we turn to the general case. From Eq. (3.187) we know that an arbitrary rotation of the coordinate system can be written as the product of three proper rotations over the Euler angles α, β and γ,

$$R(\alpha,\beta,\gamma) = R_z(\alpha)R_y(\beta)R_z(\gamma). \tag{3.197}$$

The corresponding unitary transformation is found by applying the product rule (3.177) to Eq. (3.188),

$$\begin{aligned} U(\alpha,\beta,\gamma) &= U_z(\alpha)U_y(\beta)U_z(\gamma) && (3.198)\\ &= \pm\begin{pmatrix} e^{i\alpha/2} & 0 \\ 0 & e^{-i\alpha/2}\end{pmatrix}\begin{pmatrix}\cos(\beta/2) & \sin(\beta/2)\\ -\sin(\beta/2) & \cos(\beta/2)\end{pmatrix}\begin{pmatrix} e^{i\gamma/2} & 0\\ 0 & e^{-i\gamma/2}\end{pmatrix}. && (3.199)\end{aligned}$$

The set of all 2×2 unitary matrices with determinant $+1$ constitutes a group: the special unitary group, SU(2). Writing the general element of this group as $\pm U(\alpha,\beta,\gamma)$, we find for $U(\alpha,\beta,\gamma)$ that $U(-\gamma,-\beta,-\alpha)$ is its inverse and $U(0,0,0)$ is the unit element; for $-U(\alpha,\beta,\gamma)$ the inverse is $-U(-\gamma,-\beta,-\alpha)$ and $-U(2\pi,2\pi,2\pi)$ the unit element. For both branches, the set is closed under the group operation and successive operations are associative. As the unitary operators $U(\alpha,\beta,\gamma)$ and $-U(\alpha,\beta,\gamma)$ are connected by Euler rotations over 2π we can *equally well work with one branch*, using either $U(\alpha,\beta,\gamma)$ or $-U(\alpha,\beta,\gamma)$ to represent the rotation, *provided we double the domain of the Euler angles* from an interval of 2π to an interval of 4π. This is sometimes compared to transforming a circular band into a *Möbius band.* From here on we shall use $+U(\alpha,\beta,\gamma)$ along with the 4π domain. One may argue that there is a certain elegance in using $U(\alpha,\beta,\gamma)$ rather than $-U(\alpha,\beta,\gamma)$ because the former connects to the unit matrix for $\alpha,\beta,\gamma\to 0$ (rather than for $\alpha,\beta,\gamma\to 2\pi$) but this is already a matter of taste.

Eq. (3.188) defines a double-valued map from SO(3) to SU(2),

$$R(\alpha,\beta,\gamma)\mapsto \pm U(\alpha,\beta,\gamma).$$

Both branches of the map conserve the group structure of SO(3). Mathematically, there exists a two-to-one homomorphism from SU(2) onto SO(3).[1] The group SO(3) is said to be doubly covered by SU(2). The double cover can be reduced to a single cover by extending the domain of the Euler angles to 4π. We return to the physical significance of this double covering in Section 3.9.3.

Problem 3.20. Show that any unitary 2×2 matrix $\underline{u}$ can be written in the form

$$\underline{u} = \pm\sqrt{\Delta}\begin{pmatrix} a & b\\ -b^* & a^*\end{pmatrix},$$

where $aa^*+bb^*=1$ and $\Delta\equiv\det\underline{u}=e^{i\xi}$ with ξ an arbitrary phase factor.

Solution. Since $\underline{u}$ is unitary the determinant of $\underline{u}^*$ can be expressed as $\Delta^*=\det\underline{u}^*=\det\underline{u}^\dagger=\det\underline{u}^{-1}=\Delta^{-1}$. This implies $|\Delta|^2=1$ and, hence $\Delta=e^{i\xi}$, generally an arbitrary phase factor. To demonstrate that the most general unitary 2×2 matrix can be expressed in the given form we start from

$$\underline{u}=\begin{pmatrix} a & b\\ c & d\end{pmatrix}.$$

Using Eq. (M.23) for the inverse we can equate $\underline{u}^\dagger$ and $\underline{u}^{-1}$

$$\begin{pmatrix} a^* & c^*\\ b^* & d^*\end{pmatrix}=\underline{u}^\dagger=\underline{u}^{-1}=\frac{1}{\Delta}\begin{pmatrix} d & -b\\ -c & a\end{pmatrix}.$$

Thus we find $d=a^*\Delta$ and $c=-b^*\Delta$ and

$$\underline{u}=\begin{pmatrix} a & b\\ -b^*\Delta & a^*\Delta\end{pmatrix}=\pm\sqrt{\Delta}\begin{pmatrix}\pm a\Delta^{-1/2} & \pm b\Delta^{-1/2}\\ \mp b^*\Delta^{1/2} & \pm a^*\Delta^{1/2}\end{pmatrix}.$$

Redefining $\pm a\,\Delta^{-1/2}\to a$ and $\pm b\,\Delta^{-1/2}\to b$ we obtain the desired result. □

---

[1] A homomorphism is a map from one space to another in which the algebraic structure is conserved.

3.8.4 Infinitesimal rotation operators - the case $s = 1/2$

Let us have a closer look at the unitary transformation (3.193) corresponding to a passive rotation over the angle α about the z axis,

$$U_z(\alpha) = \begin{pmatrix} e^{i\alpha/2} & 0 \\ 0 & e^{-i\alpha/2} \end{pmatrix}. \tag{3.200}$$

Using the well-known relation $e^{\pm i\varphi} = \cos\varphi \pm i\sin\varphi$ we can write $U_z(\alpha)$ in the form

$$U_z(\alpha) = \mathbb{1}\cos(\alpha/2) + i\sigma_z \sin(\alpha/2). \tag{3.201}$$

Note the appearance of the Pauli matrix σ_z. The change of $U_z(\alpha)$ by an *infinitesimal* passive rotation about the z axis is given by the partial derivative with respect to α and evaluates to

$$\frac{\partial U_z(\alpha)}{\partial \alpha} = (i\sigma_z/2)U_z(\alpha). \tag{3.202}$$

Since $U_z(0) = \mathbb{1}$ the above expression shows that σ_z satisfies the relation

$$i\sigma_z/2 = \left.\frac{\partial U_z(\alpha)}{\partial \alpha}\right|_{\alpha=0}. \tag{3.203}$$

Hence, the Pauli matrix σ_z can be obtained from the unitary transformation $U_z(\alpha)$ in the limit $\alpha \to 0$. For arbitrary α the differential equation (3.202) is solved by the exponential operator

$$U_z(\alpha) = e^{i\alpha\sigma_z/2}. \tag{3.204}$$

In other words, to determine $U_z(\alpha)$ for an arbitrary angle α all we need to know is the operator $i\sigma_z/2$. For this reason $i\sigma_z/2$ is called the *generator* of rotation about the z axis. In the language of group theory $i\sigma_z/2$ is one of the generators of the group SU(2) and $U_z(\alpha)$ is a representation of one of the elements of this group.

Since our choice of quantization axis was arbitrary Eq. (3.204) suggests the generalization

$$U_r(\varphi) = e^{i\varphi\sigma_r/2}, \tag{3.205}$$

where $U_r(\varphi)$ is the unitary transformation for a passive rotation (of the $s = \frac{1}{2}$ system) over the angle φ about the direction $\hat{\mathbf{r}}$, with $\sigma_r \equiv \hat{\mathbf{r}} \cdot \boldsymbol{\sigma}$. The correctness of this generalization follows in a few steps by expansion of the exponential operator - see Problem 3.21,

$$U_r(\varphi) = e^{i(\varphi/2)\sigma_r} = \mathbb{1}\cos(\varphi/2) + i\sigma_r \sin(\varphi/2). \tag{3.206}$$

Note that by specializing (3.206) to $\hat{\mathbf{r}} \to \hat{\mathbf{z}}$ and $\hat{\mathbf{r}} \to \hat{\mathbf{y}}$ we immediately regain the unitary matrices (3.193) and (3.195), respectively. For other directions the matrices are more complicated because σ_r only has a simple form along the x, y and z axes. In any case, the half-angle notation nicely reminds us of the domain doubling of the Euler angles.

Problem 3.21. Show that the unitary operator $U_r(\varphi)$ for the passive rotation of a $s = \frac{1}{2}$ system over the angle α about the direction $\hat{\mathbf{r}}$ can be written in the form

$$e^{i(\alpha/2)\sigma_r} = \mathbb{1}\cos(\alpha/2) + i\sigma_r \sin(\alpha/2).$$

Solution. For $s = \frac{1}{2}$ we have

$$U_r(\alpha) = e^{i\alpha S_r/\hbar} = e^{i(\alpha/2)\sigma_r} = \sum_n \frac{i^n (\alpha/2)^n \sigma_r^n}{n!}$$

Since $\sigma_r^2 = \mathbb{1}$, see Eq. (3.49), we have $\sigma_r^{2n} = 1$ and $\sigma_r^{2n+1} = \sigma_r$ and the expansion can be separated into its even and odd terms,

$$e^{i(\alpha/2)\sigma_r} = \mathbb{1}\sum_n \frac{(-1)^n (\alpha/2)^{2n}}{(2n)!} + i\sigma_r \sum_n \frac{(-1)^n (\alpha/2)^{2n+1}}{(2n+1)!}.$$

Recognizing the expansions for the sine and the cosine, this expression takes the desired form. □

3.8.5 Infinitesimal rotation operators - generalization

Let us return to Eq. (3.206). This expression holds for unitary transformations corresponding to passive rotations over a *finite* angle. Its validity is restricted to the case $s = \frac{1}{2}$ because the sine/cosine decomposition relies on the property $\sigma_r^2 = \mathbb{1}$ of the Pauli matrix (see Problem 3.21). Interestingly, this restriction does not hold for *infinitesimal* rotations. As we shall see below, an infinite product of infinitesimal rotations also leads to the exponential relation (3.205), even if the condition $\sigma_r^2 = \mathbb{1}$ is *not* imposed.

To demonstrate this generalization, we analyze $U_r(\varphi)$ as the product of n subsequent rotations over the angle φ/n (about the direction $\hat{\mathbf{r}}$). For $n \to \infty$ this product becomes an infinite product of infinitesimal rotations,

$$U_r(\varphi) = \lim_{n\to\infty} \left[U_r(\varphi/n)\right]^n . \tag{3.207}$$

For infinitesimal angles Eq. (3.206) reduces to

$$U_r(\varphi/n)|_{n\to\infty} = \mathbb{1} + (i\varphi/2n)|_{n\to\infty}\sigma_r. \tag{3.208}$$

Recalling Eq. (3.43) we substitute $i\sigma_r/2 = iS_r/\hbar$. Evaluating the infinite product (3.207) we find

$$U_r(\varphi) = \lim_{n\to\infty} \left(\mathbb{1} + i\frac{\varphi}{n}S_r/\hbar\right)^n = e^{i\varphi S_r/\hbar}. \tag{3.209}$$

This result is obtained without imposing the condition $\sigma_r^2 = \mathbb{1}$ (see Problem 3.22). Rearranging Eq. (3.208) we find that any operator $iS_r/\hbar$ that satisfies the relation (3.208) can be interpreted as the operator for an infinitesimal small rotation about the direction $\hat{\mathbf{r}}$,

$$iS_r/\hbar = \lim_{n\to\infty} \frac{U_r(\varphi/n) - \mathbb{1}}{\varphi/n} = \left.\frac{\partial U_r(\varphi)}{\partial\varphi}\right|_{\varphi=0} . \tag{3.210}$$

Problem 3.22. Show that the unitary operator $U_r(\varphi)$, corresponding to a passive rotation over the angle φ about the direction $\hat{\mathbf{r}}$, can be written as an exponential operator of $S_r \equiv \hat{\mathbf{r}}\cdot\mathbf{S}$

$$U_r(\varphi) = \lim_{n\to\infty} \left(\mathbb{1} + i\frac{\varphi}{n}S_r/\hbar\right)^n = e^{i\varphi S_r/\hbar},$$

irrespective of the value of the quantum number s.

Solution. The unitary operator for an infinitesimally small (but nonzero) passive rotation over the angle $(\varphi/n)|_{n\to\infty}$ about the direction $\hat{\mathbf{r}}$, is given by

$$U_r(\varphi/n)|_{n\to\infty} = \mathbb{1} + (i\frac{\varphi}{n}S_r/\hbar)|_{n\to\infty}.$$

Substituting this expression into (3.207) we obtain

$$U_r(\varphi) = \lim_{n\to\infty} \left(\mathbb{1} + i\frac{\varphi}{n}S_r/\hbar\right)^n = \lim_{n\to\infty} \sum_{k=0}^{n} \binom{n}{k} (i\varphi S_r/\hbar)^k \text{ with } \binom{n}{k} = \frac{n!}{k!(n-k)!}.$$

Substituting the values for the binomial coefficients we obtain

$$\begin{aligned} U_r(\varphi) = \lim_{n\to\infty} \Bigg[\bigg(&1 + i\varphi S_r/\hbar + \frac{n(n-1)}{2!}\frac{1}{n^2}(i\varphi S_r/\hbar)^2 + \frac{n(n-1)(n-2)}{3!}\frac{1}{n^3}(i\varphi S_r/\hbar)^3 + \cdots \\ &\cdots + n\frac{1}{n^{n-1}}(i\varphi S_r/\hbar)^{n-1} + \frac{1}{n^n}(i\varphi S_r/\hbar)^n\bigg). \end{aligned}$$

Rewriting this expression as an expansion in powers of $(1/n)$ it becomes

$$\begin{aligned} U_r(\varphi) &= \lim_{n\to\infty} \left(1 + i\varphi S_r/\hbar + \frac{1}{2!}(1 - \frac{1}{n})(i\varphi S_r/\hbar)^2 + \frac{1}{3!}(1 - \frac{3}{n} + \frac{2}{n^2})(i\varphi S_r/\hbar)^3 + \cdots\right) \\ &= 1 + i\varphi S_r/\hbar + \frac{1}{2!}(i\varphi S_r/\hbar)^2 + \frac{1}{3!}(i\varphi S_r/\hbar)^3 + \cdots , \end{aligned}$$

where all terms depending on n have vanished. In the last line we recognize the expansion of the exponential operator - see Eq. (L.31). As no presumptions are made with respect to the actual value of the spin, this result holds for any value of s. □

3.9 Angular momentum

3.9.1 Introduction

In Section 3.1 we established that a vector operator $\mathbf{J}$ caries the properties of angular momentum (as introduced in Chapter 1) if its cartesian components J_x, J_y and J_z are hermitian operators that satisfy the commutation relations (3.1). In the present section we shall make a fresh start and define angular momentum as an infinitesimal rotation imposed on a physical system. As we shall see, this definition leads in a few steps to conditions of Section 3.1.

To set the stage, we consider a *stationary state* of the Schrödinger Hamiltonian, $\psi_{nlm}(\mathbf{r})$, where $\mathbf{r} = (r, \theta, \phi)$ is the position with respect to the center of rotation (in spherical coordinates). We introduce an operator $U_z(\Delta\phi)$ to impose on ψ_{nlm} a passive rotation over the angle $\Delta\phi$ about the z axis. At this point $U_z(\Delta\phi)$ is unknown but has to be unitary in order to conserve the normalization of the state under rotation. Then, the change of ψ_{nlm} by an *infinitesimal* passive rotation about the z axis can be expressed in terms of $U_z(\Delta\phi)$ by evaluating the partial derivative of ψ_{nlm} with respect to ϕ,

$$\begin{aligned}\frac{\partial\psi_{nlm}(r,\theta,\phi)}{\partial\phi} &\equiv \lim_{\Delta\phi\to0}\frac{\psi_{nlm}(r,\theta,\phi+\Delta\phi)-\psi_{nlm}(r,\theta,\phi)}{\Delta\phi}\\ &= \lim_{\Delta\phi\to0}\frac{U_z(\Delta\phi)\,\psi_{nlm}(r,\theta,\phi)-\psi_{nlm}(r,\theta,\phi)}{\Delta\phi}\\ &= \lim_{\Delta\phi\to0}\frac{U_z(\Delta\phi)-1}{\Delta\phi}\psi_{nlm}(r,\theta,\phi)\,. \end{aligned} \tag{3.211}$$

As this expression holds for arbitrary $\psi_{nlm}(\mathbf{r})$ the partial derivative can be expressed in the form

$$\frac{\partial}{\partial\phi} = \lim_{n\to\infty}\frac{U_z(\phi/n)-1}{\phi/n} = \left.\frac{\partial U_z(\phi)}{\partial\phi}\right|_{\phi=0}. \tag{3.212}$$

Here we defined $\Delta\phi \equiv \phi/n$, with integer n. In this notation, the (unknown) unitary operator $U_z(\phi/n)\,|_{n\to\infty}$ corresponds to a passive rotation over the *infinitesimal* angle $\delta\phi = (\phi/n)\,|_{n\to\infty}$ about the z axis.

At this point we leave the mathematical convention of passive rotations to give preference to physical rotations of the system. In this way we conform ourselves to the convention of Chapter 1 in which the orbital angular momentum, $\mathbf{L} = \mathbf{r}\times\mathbf{p}$, is defined as a right-handed rotation of the physical system. This change of convention is simple to implement because a *physical* rotation over the angle α about the arbitrary direction $\hat{\mathbf{a}}$ is equivalent to a *passive* rotation over the angle $-\alpha$ about the same axis. Then, the unitary operator $P_a(\alpha)$ corresponding to a *physical* rotation over the angle α about the direction $\hat{\mathbf{a}}$ is defined as

$$P_a(\alpha) \equiv U_a(-\alpha)\,. \tag{3.213}$$

As an aside we mention that by inverting the direction of $\hat{\mathbf{a}}$ we have

$$P_{-a}(\alpha) = P_a(-\alpha) = U_a(\alpha)\,. \tag{3.214}$$

Recalling Eq. (1.25) we find that the operator for *orbital angular momentum* about the z axis is given by

$$L_z = -i\hbar\frac{\partial}{\partial\phi} = i\hbar\lim_{n\to\infty}\frac{P_z(\phi/n)-1}{\phi/n} = i\hbar\left.\frac{\partial P_z(\phi)}{\partial\phi}\right|_{\phi=0}, \tag{3.215}$$

where an explicit expression for $P_z(\phi)$ remains to be obtained. Note that L_z is hermitian.

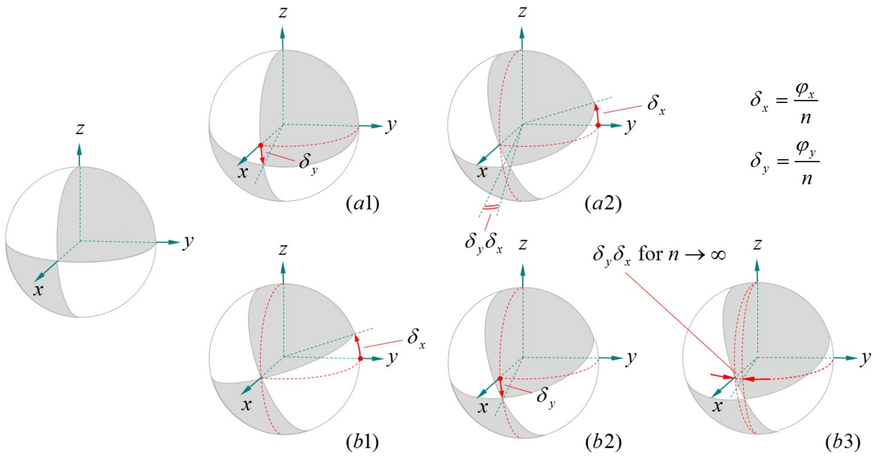

Figure 3.9: Infinitesimal rotations do not commute. Upper part: ($a1$) rotation of a ball about the y axis; ($a2$) rotation about the x axis. Lower part: ($b1$) rotation of the ball about the x axis; ($b2$) rotation about y axis; ($b3$) additional rotation required to obtain the same orientation as shown in ($a2$). All figures show the orientation of the ball *after* rotation over the angle indicated by the arrow.

3.9.2 Differential operators - formal definition of angular momentum operators

In the previous section we found that orbital angular momentum can be represented by a unitary operator which imposes an infinitesimal rotation on the wavefunction of a physical system. The expressions (3.210) and (3.215) suggest to define any type of angular momentum in terms of a differential operator,

$$-iJ_a/\hbar \equiv \lim_{n\to\infty} \frac{P_a(\varphi/n) - \mathbb{1}}{\varphi/n} = \left.\frac{\partial P_a(\varphi)}{\partial\varphi}\right|_{\varphi=0}. \tag{3.216}$$

Here $P_a\,(\varphi/n)\,|_{n\to\infty}$ is the unitary operator corresponding to the *physical* rotation over the infinitesimal angle $\delta\varphi = \varphi/n|_{n\to\infty}$ about the direction $\hat{\mathbf{a}}$ and $\mathbb{1}$ is the unit operator. Inverting Eq. (3.216) we obtain for $P_a(\delta\varphi)$ the operator identity

$$P_a\,(\varphi/n)\,|_{n\to\infty} = \mathbb{1} - (i\varphi/n)|_{n\to\infty} J_a/\hbar. \tag{3.217}$$

Note that this expression is unitary ($P_a^\dagger = P_a^{-1}$) provided the operator

$$J_a \equiv \hat{\mathbf{a}}\cdot\mathbf{J} \tag{3.218}$$

is hermitian ($J_a^\dagger = J_a$). The unitary operator for a rotation over the *finite* angle φ about the direction $\hat{\mathbf{a}}$ is given by the following infinite product of infinitesimal operators (see Problem 3.22),

$$P_a(\varphi) \equiv \lim_{n\to\infty}\left(\mathbb{1} - i\frac{\varphi}{n}J_a/\hbar\right)^n = e^{-i\varphi J_a/\hbar}. \tag{3.219}$$

The significance of Eqs. (3.216)-(3.219) can hardly be over-emphasized because the properties of angular momentum follow in a few lines from the definition (3.216). To convince ourselves, all we need to do is show that the criteria for angular momentum operators (as introduced in Section 3.1) are satisfied; i.e., J_a has to be hermitian (as we already established above) and the cartesian components J_x, J_y and J_z have to satisfy the commutation relations (3.1). As we will make no assumption about the type of system under rotation such as the dimension of the subspace in which $P_a(\varphi)$ operates, our definition holds for *any* type of angular momentum.

To obtain the commutation relations (3.1) we use a geometrical argument by noting that infinitesimal rotations do not commute. This is illustrated in Fig. 3.9. In the upper part of the figure

$(a1)$ we first rotate a ball over the angle $\delta_y = \varphi_y/n$ about the y axis and $(a2)$ subsequently $\delta_x = \varphi_x/n$ about the x axis. In the lower part $(b1)$ we first rotate over the angle δ_x about the x axis and $(b2)$ subsequently δ_y about the y axis. Comparing $(a2)$ and $(b2)$ we find that in the latter case it takes a small additional rotation $\delta_y\delta_x = \varphi_x\varphi_y/n^2$ to realize the orientation of $(a2)$. In the limit $n \to \infty$ this additional rotation is about the z axis as indicated in $(b3)$,

$$\lim_{n\to\infty} \left[P_x(\varphi_x/n)P_y(\varphi_y/n) - P_z(\varphi_x\varphi_y/n^2)P_y(\varphi_y/n)P_x(\varphi_x/n)\right] = 0. \tag{3.220}$$

Expanding the exponential operators to lowest non-vanishing order in $1/n$ we obtain

$$\left(\varphi_x\varphi_y/n^2\right)(J_yJ_x - J_xJ_y)/\hbar^2 - i\left(\varphi_x\varphi_y/n^2\right)J_z/\hbar = 0 \quad \Leftrightarrow \quad [J_x, J_y] = i\hbar J_z \tag{3.221}$$

and by cyclic permutation we find also the other commutation relations of the set (3.1). From this point on all properties of angular momentum follow from the algebra developed in Section 3.1.

Example 1 - hydrogenic wavefunctions

At this point we are in the position to calculate actual rotations. First, we demonstrate this for a rotation of the orbital wavefunction $\psi_{nlm}(r,\theta,\phi)$ about the z axis. Specializing to orbital angular momentum we calculate

$$P_z(\varphi)\psi_{nlm}(r,\theta,\phi) = e^{-i\varphi L_z/\hbar}\psi_{nlm}(r,\theta,\phi) = e^{-im\varphi/\hbar}\psi_{nlm}(r,\theta,\phi), \tag{3.222}$$

where we used $L_z\psi_{nlm} = -i\hbar\partial_\phi\psi_{nlm} = m\hbar\psi_{nlm}$ (see Section 1.1.3). In particular, we have $P_z(2\pi)\psi_{nlm}(r,\theta,\phi) = \psi_{nlm}(r,\theta,\phi)$.

Example 2 - angular momentum states in Dirac notation

Turning to the general case, we consider the eigenstates $\{|j,m\rangle\}$ of the angular momentum operators $\mathbf{J}^2$ and J_z. In this case the effect of an arbitrary rotation about the direction $\hat{\mathbf{a}}$ is given by

$$P_a(\varphi)|j,m\rangle = \sum_{m'} |j,m'\rangle\langle j,m'|e^{-i\varphi J_a/\hbar}|j,m\rangle. \tag{3.223}$$

The unitary matrix

$$[P_a(\varphi)]_{m'm} \equiv \langle j,m'|e^{-i\varphi J_a/\hbar}|j,m\rangle, \tag{3.224}$$

is called a *linear representation* of the rotation operator, $P_a(\varphi)$. In principle, the operators $P_a(\varphi)$, $\mathbb{1}$ and J_a operate on vectors of the full Hilbert space of $\mathbf{J}^2$ and J_z but as the $P_a(\varphi)$ do not mix states differing in j we can restrict ourselves - for given j - to the corresponding $d = 2j+1$ dimensional subspace V^d of Hilbert space. This block-diagonal form of the matrix (3.224) is called the *irreducible* form of the angular momentum representation. In particular, the eigenstates $|j,m\rangle$ transform in accordance with *one* of the irreducible representations of the full rotation group (the one corresponding to the value j). Recalling the identity (3.213), we note that by specializing the matrix (3.224) to the case $j = \frac{1}{2}$ we regain the Eqs. (3.193) and (3.195).

For a given basis $\{|j,m\rangle\}$ the unitary transformations $P_a(\varphi)$ (corresponding to proper rotations about the direction $\hat{\mathbf{a}}$ in real space) can be generated with the aid of Eq. (3.224). The set of all $P_a(\varphi)$ constitutes a *group*, the group SU(2). The general element of this group is $P_a(\varphi)$, $P_a(-\varphi)$ is its inverse and for $\varphi = 0$ we obtain the unit element. Moreover, the set is closed under the group operation. The operators J_a are called the *generators* of the group. The rotation matrices $[P_a(\varphi)]_{m'm}$ are called *representations* of the group. Depending on the dimension $d = 2j+1$ of the basis $\{|j,m\rangle\}$ the operators $P_z(\varphi)$ generate $d = 1, 2, 3, \cdots$ dimensional *irreducible* representations of the group SU(2). Note that in Section 3.8.3 the above was already established for the special case $s = \frac{1}{2}$ without introducing differential operators. This case is called the *fundamental* representation of the group SU(2).

3.9.3 Integral versus half-integral angular momentum

We are now equipped to analyze the effect of a physical rotation on a system of arbitrary angular momentum. This will lead us to an important insight in the difference between integer and half-integer angular momenta. We consider for this purpose a system of angular momentum j, with $\{|j,m\rangle\}$ being the basis defined by the operators $\mathbf{J}^2$ and J_z. An arbitrary state $|\chi\rangle$ of this system can be decomposed in the form

$$|\chi\rangle = \sum_{m=-j}^{j} |j,m\rangle\langle j,m|\chi\rangle. \tag{3.225}$$

Now we apply a physical rotation of this system over 2π about the z axis. Setting $\hat{\mathbf{a}} \to \hat{\mathbf{z}}$ and $\varphi \to 2\pi$ in Eq. (3.219) we find for the corresponding unitary transformation

$$P_z(2\pi)|\chi\rangle = e^{-i2\pi J_z/\hbar}|\chi\rangle = \sum_{m=-j}^{j} e^{-i2\pi m}|j,m\rangle\langle j,m|\chi\rangle. \tag{3.226}$$

Note that each term contains the same phase factor, $+1$ for integral j and -1 for half-integral j. Thus we obtain

$$P_z(2\pi)|\chi\rangle = \begin{cases} \ \ |\chi\rangle \text{ for integral } j \\ -|\chi\rangle \text{ for half-integral } j. \end{cases} \tag{3.227}$$

Note that for integral j the rotation properties are regular; i.e., all eigenfunctions of the decomposition are in phase after rotation of the physical system over 2π. This is readily verified for the spherical harmonics derived from the Schrödinger equation in Section 1.1.3. In contrast, for half-integral angular momentum we find $P_z(2\pi+\varphi) = -P_z(\varphi)$ and we have to *rotate over an additional* 2π (4π in total) to recover the original state $|\chi\rangle$. This was first demonstrated in 1975 in famous neutron interferometry experiments [90, 121]. Obviously, in the real space of the laboratory the range of angles $0 \leq \varphi < 2\pi$ is not distinguishable from the range $2\pi \leq \varphi < 4\pi$. Therefore, the unitary transformations of the group SU(2) capture a property of half-integral angular momenta that is absent in the real space rotation matrices of the group SO(3) - *spin differs from classical rotation*. For a given physical rotation over the angle φ (about the z axis) we can equally well choose $P_z(\varphi)$ or $-P_z(\varphi)$ to describe the corresponding unitary transformation. Recall that we arrived at same conclusion in Section 3.8.3. Apparently, the "wavefunctions" of half-integral spin systems are double-valued functions as was first noticed by Wolfgang Pauli [80]. These wavefunctions are called spinors to distinguish their rotation properties from those of the (single-valued) states of integer angular momenta (the spherical harmonics). Experimentally this double valuedness is of no consequence because the global phase of the state does not affect the expectation values of the angular momentum operators. In Section 3.11 we discuss how to generate matrix representations for unitary transformations of arbitrary angular momenta and illustrate this for the examples $s = \frac{1}{2}$ and $s = 1$.

Importantly, the double covering is of no consequence for unitary transformations of the *operators* because the transformation (3.175) involves U and $U^\dagger$ symmetrically. This causes the sign of U to drop out of the transformation; i.e., it does not affect expectation values - as expected for observables. In contrast, the double covering has important consequences for the *states* as these become double valued as expressed by Eqs. (3.194) and (3.196). So, whereas the operators transform like classical angular momentum operators, the transformation properties of the states have no classical analogue.

3.9.4 Physical rotation of angular momentum systems - general case

Our next task is to generalize the discussion to include rotations about arbitrary axes. According to the Euler rotation theorem, any *passive* rotation R can be written as three subsequent coordinate rotations over the Euler angles α, β and γ: $R(\alpha,\beta,\gamma) = R_{z''}(\gamma)R_{y'}(\beta)R_z(\alpha)$. To obtain the corresponding *physical* rotation $R_P(\alpha,\beta,\gamma)$ we invert the subsequent Euler rotations,

$$R_P(\alpha,\beta,\gamma) = R_{z''}(-\gamma)R_{y'}(-\beta)R_z(-\alpha) = R(-\alpha,-\beta,-\gamma). \tag{3.228}$$

Note that $R_P(\alpha,\beta,\gamma) \neq R^{-1}(\alpha,\beta,\gamma) = R(-\gamma,-\beta,-\alpha)$. Next, the physical rotation is expressed in terms of rotations about laboratory-fixed axes with the aid of Eq. (3.187),

$$R_P(\alpha,\beta,\gamma) = R(-\alpha,-\beta,-\gamma) = R_z(-\alpha)R_y(-\beta)R_z(-\gamma). \tag{3.229}$$

Changing to the corresponding unitary transformation (see Sections 3.8.4 and 3.9.1) we arrive at

$$P_R \equiv P(\alpha,\beta,\gamma) = U(-\alpha,-\beta,-\gamma) = P_z(\alpha)P_y(\beta)P_z(\gamma) = e^{-i\alpha J_z/\hbar}e^{-i\beta J_y/\hbar}e^{-i\gamma J_z/\hbar}. \tag{3.230}$$

The rotation matrices $\mathscr{D}^j_{m'm}$

Knowing the unitary matrices corresponding to the Euler rotations we can write the unitary transformations corresponding to an arbitrary physical rotation as

$$|\chi\rangle' = P_R|\chi\rangle = \sum_{m,m'=-j}^{+j} |j,m'\rangle\langle j,m'|P_R|j,m\rangle\langle j,m|\chi\rangle. \tag{3.231}$$

The rotation matrix element is commonly denoted by

$$\mathscr{D}^j_{m'm}(\alpha,\beta,\gamma) \equiv \langle j,m'|P_R(\alpha,\beta,\gamma)|j,m\rangle. \tag{3.232}$$

In view of the diagonality of P_z the rotation matrix simplifies to

$$\mathscr{D}^j_{m'm}(\alpha,\beta,\gamma) = \langle j,m'|e^{-i\alpha J_z/\hbar}P_y(\beta)e^{-i\gamma J_z/\hbar}|j,m\rangle = e^{-im'\alpha}d^j_{m'm}(\beta)e^{-im\gamma}, \tag{3.233}$$

where the matrix $d^j_{m'm}(\beta)$ is given by

$$d^j_{m'm}(\beta) \equiv \langle j,m'|e^{-i\beta J_y/\hbar}|j,m\rangle. \tag{3.234}$$

It is straightforward to evaluate this matrix for any integral or half-integral value of j (see Problems 3.26 and 3.27 for the case $j=\frac{1}{2}$). A general formula for the matrix elements $d^j_{m'm}(\beta)$ was derived by Wigner [122]

$$d^j_{m'm}(\beta) = \sum_\kappa \frac{(-1)^\kappa\sqrt{(j+m')!(j-m')!(j+m)!(j-m)!}}{(j+m'-\kappa)!(j-m-\kappa)!\kappa!(\kappa-m'+m)!} \times [\cos(\beta/2)]^{2j+m'-m-2\kappa}[\sin(\beta/2)]^{2\kappa-m'+m}, \tag{3.235}$$

where the summation runs over all values of κ for which the factorials are meaningful. Note that the $d^j_{m'm}(\beta)$ are *real*, which explains, in hindsight, the preference for the $z-y-z$ rotation sequence - See Fig. 3.7. The Wigner formula is easily embedded in computer algebra to manipulate angular momenta of arbitrary size on their generalized Bloch sphere.

Problem 3.23. Show that pure rotations about the x, y and z directions are given by

$$P_z(\alpha) = P(\alpha,0,0),\;\; P_y(\beta) = P(0,\beta,0),\;\; P_x(\beta) = P(-\tfrac{1}{2}\pi,\beta,\tfrac{1}{2}\pi).$$

3.9.5 Spherical tensor operators - irreducible tensor operators

Substituting an eigenstate into Eq. (3.231), $|\chi\rangle \to |k,q\rangle$, we obtain an expression for the transformation of eigenstates under rotation

$$|k,q\rangle' = \sum_{q'} |k,q'\rangle \mathscr{D}^k_{q'q}(\alpha,\beta,\gamma). \tag{3.236}$$

Turning to the position representation, $\langle \hat{\mathbf{r}}|k,q\rangle = Y^q_k(\hat{\mathbf{r}})$, we obtain the transformation properties of the $Y^q_k(\hat{\mathbf{r}})$,

$$Y^q_k(\hat{\mathbf{r}}') = \sum_{q'} Y^{q'}_k(\hat{\mathbf{r}}) \mathscr{D}^k_{q'q}(\alpha,\beta,\gamma). \tag{3.237}$$

In particular, for $\hat{\mathbf{r}} = \hat{\mathbf{z}}$ only the term $q' = 0$ contributes to the summation - see Eq. L.55 - and we find the following relation between the spherical harmonics and the rotation matrices:

$$Y^q_k(\hat{\mathbf{r}}') = \sqrt{\frac{2l+1}{4\pi}} \mathscr{D}^k_{0,q}(\hat{\mathbf{r}}'). \tag{3.238}$$

In Section 3.1.1 we established that the standard components of $\mathbf{J}$ transform like the $Y^q_1(\hat{\mathbf{r}})$. So, replacing in Eq. (3.237) $Y^q_k(\hat{\mathbf{r}})$ by $J_q \in \{J_{-1}, J_0, J_{+1}\}$ we find for the transformation properties of the standard components of $\mathbf{J}$

$$J'_q = \sum_{q'=-1}^{+1} J_{q'} \mathscr{D}^1_{q'q}(\alpha,\beta,\gamma). \tag{3.239}$$

Combining this expression with Eq. (3.175) we obtain

$$J'_q = P_R(\alpha,\beta,\gamma) J_q P^{\dagger}_R(\alpha,\beta,\gamma) = \sum_{q'=-1}^{+1} J_{q'} \mathscr{D}^1_{q'q}(\alpha,\beta,\gamma). \tag{3.240}$$

The above procedure can be generalized by introducing *spherical tensor operators* $\mathrm{T}^{(k)}$ as operators with standard components that transform like $Y^q_k(\hat{\mathbf{r}})$ [93]. This restricts the rank of the tensor to *integer* values, $k \in \{0, 1, \cdots\}$. Replacing in Eq. (3.237) the $Y^q_k(\hat{\mathbf{r}})$ by the standard components $T_{k,q} \in \{T_{k,-k}, \cdots, T_{k,k}\}$ we obtain

$$T'_{kq} = P_R T_{kq} P^{\dagger}_R = \sum_{q'=-k}^{+k} T_{kq'} \mathscr{D}^k_{q'q}. \tag{3.241}$$

As was first demonstrated by Giulio Racah [86] these transformation properties are valid for any tensor operator T_{kq} that satisfies the following commutation relations (see Problem K.1):

$$[J_z, T_{k,q}] = q\hbar T_{k,q} \tag{3.242a}$$

$$[J_{\pm}, T_{k,q}] = \sqrt{k(k+1) - q(q\pm 1)}\, \hbar T_{k,q\pm 1}. \tag{3.242b}$$

Operators satisfying these commutation relations are called *irreducible tensor operators*. They act within the invariant subspace of a *pure* angular momentum state (for given j, the subspace spanned by the basis $\{|j,m\rangle\}$, with $-j \le m \le j$ - see Section 3.1). Angular momentum operators are irreducible tensor operators of rank 1 ($T_{1,q} \to J_q$). For these operators the commutation relations (3.242) reduce to those of angular momentum (cf. Appendix K.1.2). The simplest class of irreducible tensor operators are the spherical tensor operators of rank 0. These are known as *scalar invariants.* They have a single component, T_{00}, which is invariant under rotation ($\mathscr{D}^0_{00} = 1$),

$$T'_{00} = P_R T_{00} P^{\dagger}_R = T_{00}. \tag{3.243}$$

The Hamiltonian of systems of identical particles can only involve irreducible tensor operators of *integral* rank since half-integral ranks would give rise to transitions between bosonic and fermionic states, which contradicts the experimental observation that the statistical nature of particles is rigorously conserved (cf. Section 3.4.6).

3.10 Composition and reduction of tensor operators

3.10.1 Composition of tensor operators

Let us return to the *Clebsch-Gordan transformation* for the states

$$|k,q\rangle = \sum_{m=-j_1}^{j_1}\sum_{m=-j_2}^{j_2} |j_1,m_1;j_2,m_2\rangle\langle j_1,m_1;j_2,m_2|k,q\rangle. \tag{3.244}$$

We recall from Section 3.9.5 that the standard components $T_{l,m}$ of the spherical tensor operator $\mathrm{T}^{(l)}$ transform under rotation like the $Y_l^m(\hat{\mathbf{r}}) = \langle\hat{\mathbf{r}}|l,m\rangle$. Generalizing the transformation properties to tensors of arbitrary rank, we find that starting from two irreducible tensor operators, $\mathrm{T}_1^{(j_1)}$ and $\mathrm{T}_2^{(j_2)}$, we can construct irreducible operators of rank k with the aid of the transformation[1]

$$[\mathrm{T}_1^{(j_1)}\otimes\mathrm{T}_2^{(j_2)}]_q^k = \sum_{m=-j_1}^{j_1}\sum_{m=-j_2}^{j_2} T_{1:j_1,m_1}T_{2:j_2,m_2}\langle j_1,m_1;j_2,m_2|k,q\rangle. \tag{3.245}$$

Here, the $[\mathrm{T}_1^{(j_1)}\otimes\mathrm{T}_2^{(j_2)}]_q^k$ represent the $(2k+1)$ standard components of the irreducible tensor operator $[\mathrm{T}_1^{(j_1)}\otimes\mathrm{T}_2^{(j_2)}]^{(k)}$. The operator $[\mathrm{T}_1^{(j_1)}\otimes\mathrm{T}_2^{(j_2)}]$ is called the *direct product* of the Tensor operators $\mathrm{T}_1^{(j_1)}$ and $\mathrm{T}_2^{(j_1)}$. In matrix notation, the operator $\mathrm{T}^{(\mathrm{j})}$ is represented by a $(2j+1)\times(2j+1)$ matrix; i.e., it acts in a $(2j+1)$-dimensional space. Turning to $3j$ symbols and using the projection rule (J.5) the decomposition (3.245) takes the form

$$[\mathrm{T}_1^{(j_1)}\otimes\mathrm{T}_2^{(j_2)}]_q^k = \sum_{m=-j_1}^{j_1} T_{1:j_1,m}T_{2:j_2,(q-m)}(-1)^{j_1-j_2+q}\sqrt{2k+1}\begin{pmatrix} j_1 & j_2 & k\\ m & q-m & -q\end{pmatrix}. \tag{3.246}$$

Note that the triangle inequality for $3j$ symbols restricts the rank of $[\mathrm{T}_1^{(j_1)}\otimes\mathrm{T}_2^{(j_1)}]^{(k)}$ to the interval

$$|j_1-j_2|\le k\le j_1+j_2. \tag{3.247}$$

The operator $[\mathrm{T}_1^{(j_1)}\otimes\mathrm{T}_2^{(j_2)}]$ acts in a $(2j_1+1)(2j_2+1)$-dimensional space and is represented by a $(2j_1+1)(2j_2+1)\times(2j_1+1)(2j_2+1)$ matrix, which is in index notation given by $T_{1:j_1,m_1}T_{2:j_2,m_2}$.

Tensor contraction - invariance

Specializing to the case $j_1=j_2=j$ we find that for every two irreducible tensor operator $T_1^{(j)}$ and $T_2^{(j)}$ we can construct a scalar operator $(k=q=0)$, which, like $Y_0^0(\hat{\mathbf{r}})$, is invariant under pure rotations,

$$[\mathrm{T}_1^{(j)}\otimes\mathrm{T}_2^{(j)}]_0^0 = \sum_{m=-j}^{j} T_{1:j,m}T_{2:j,-m}\begin{pmatrix} j & j & 0\\ m & -m & 0\end{pmatrix} = \sum_{m=-j}^{j} T_{1:j,m}T_{2:j,-m}\frac{(-1)^{j-m}}{\sqrt{2j+1}}. \tag{3.248}$$

In case $\mathrm{T}_1^{(j)}=\mathrm{T}_2^{(j)}=T^{(j)}$ this invariant is called the *Casimir invariant* of the tensor $T^{(j)}$.

---

[1] Note that two irreducible tensor operators of the same rank have the same transformation properties; hence are the same up to a scalar multiplyer.

3.10.2 Reduction of products of tensor operators

We now consider the *inverse* Clebsch-Gordan transformation for the states,

$$|j_1,m_1;j_2,m_2\rangle = \sum_{k=|j_1-j_2|}^{j_1+j_2} \sum_{q=-k}^{k} |k,q\rangle\langle k,q|j_1,m_1;j_2,m_2\rangle. \tag{3.249}$$

we find by following an analogous procedure that the tensor product of two irreducible tensor operators of rank j_1 and j_2 can be written as the sum of irreducible tensor operators of rank k, with k again restricted to the interval (3.247),

$$T_{1:j_1m_1}T_{2:j_2m_2} = \sum_{k=|j_1-j_2|}^{j_1+j_2} T_{3:k,q}(-1)^{j_1-j_2+q}\sqrt{2k+1}\begin{pmatrix} j_1 & j_2 & k \\ m_1 & m_2 & -q \end{pmatrix}\delta_{q,(m_1+m_2)}. \tag{3.250}$$

The $T_{1:j_1m_1}T_{2:j_2m_2}$ are the $(2j_1+1)(2j_2+1)$ tensor components of the tensor operator $[\mathrm{T}_1^{(j_1)}\otimes\mathrm{T}_2^{(j_2)}]$, which is the direct product of the operators $\mathrm{T}_1^{(j_1)}$ and $\mathrm{T}_2^{(j_1)}$. Eq. (3.250) shows that $[\mathrm{T}_1^{(j_1)}\otimes\mathrm{T}_2^{(j_1)}]$ can written as the *direct* sum of irreducible tensor operators,[1]

$$[\mathrm{T}_1^{(j_1)}\otimes\mathrm{T}_2^{(j_1)}] = [\mathrm{T}_1^{(j_1)}\otimes\mathrm{T}_2^{(j_1)}]^{(|j_1-j_2|)}\oplus\cdots\oplus[\mathrm{T}_1^{(j_1)}\otimes\mathrm{T}_2^{(j_1)}]^{(j_1+j_2)}. \tag{3.251}$$

This decomposition is called *reduction* of the $(2j_1+1)(2j_2+1)$ tensor components of $[\mathrm{T}_1^{(j_1)}\otimes\mathrm{T}_2^{(j_1)}]$ into the *direct* sum of the standard components of all irreducible tensor operators $[\mathrm{T}_1^{(j_1)}\otimes\mathrm{T}_2^{(j_1)}]^{(k)}$,

$$(2j_1+1)(2j_2+1) = \sum_{k=|j_1-j_2|}^{j_1+j_2}(2k+1). \tag{3.252}$$

In the matrix representation this implies that the $(2j_1+1)(2j_2+1)\times(2j_1+1)(2j_2+1)$ matrix representing the operator $[\mathrm{T}_1^{(j_1)}\otimes\mathrm{T}_2^{(j_1)}]$ is transformed into a block-diagonal form with $(2k+1)\times(2k+1)$ matrices along the diagonal, each representing one of the irreducible operators $[\mathrm{T}_1^{(j_1)}\otimes\mathrm{T}_2^{(j_1)}]^{(k)}$. The latter are called irreducible because they cannot be reduced into blocks of lower dimension.

3.10.3 Clebsch-Gordan transformation for the rotation matrices

Sandwiching the rotation operator $P_R(\alpha,\beta,\gamma)$ between the inverse Clebsch-Gordan transformation (3.249) and its hermitian conjugate we obtain two expressions for the rotation matrices. On the l.h.s. we have

$$\begin{aligned}\mathscr{D}^{j_1}_{m_1',m_1}\mathscr{D}^{j_2}_{m_2',m_2} &= \langle j_1,m_1'|P_R(\alpha,\beta,\gamma)|j_1,m_1\rangle\langle j_2,m_2'|P_R(\alpha,\beta,\gamma)|j_2,m_2\rangle \\ &= \langle j_1,m_1';j_2,m_2'|P_R(\alpha,\beta,\gamma)|j_1,m_1;j_2,m_2\rangle. \end{aligned} \tag{3.253}$$

On the r.h.s we find

$$\begin{aligned}&\sum_{k=|j_1-j_2|}^{j_1+j_2}\sum_{q,q'=-k}^{k}\langle j_1,m_1';j_2,m_2'|k,q'\rangle(k,q'|P_R(\alpha,\beta,\gamma)|k,q)\langle k,q|j_1,m_1;j_2,m_2\rangle = \\ &\qquad = \sum_{k=|j_1-j_2|}^{j_1+j_2}\sum_{q,q'=-k}^{k}\langle j_1,m_1';j_2,m_2'|k,q'\rangle\mathscr{D}^k_{q',q}\langle k,q|j_1,m_1;j_2,m_2\rangle. \end{aligned} \tag{3.254}$$

---

[1] The sum of *non-intersecting* maps is called the *direct* sum of these maps.

Equating the two sides we obtain the Clebsch-Gordan transformation for the rotation matrices

$$\mathscr{D}^{j_1}_{m_1',m_1}\mathscr{D}^{j_2}_{m_2',m_2} = \sum_{k=|j_1-j_2|}^{j_1+j_2}\sum_{q,q'=-k}^{k}\langle j_1,m_1';j_2,m_2'|k,q'\rangle\mathscr{D}^{k}_{q',q}\langle k,q|j_1,m_1;j_2,m_2\rangle. \tag{3.255}$$

Problem 3.24. Derive the Gaunt integral (L.58).

Solution. We start from Eq. (3.238) and express the spherical harmonics in terms of the rotation matrices

$$Y^{m_1}_{j_1}(\hat{\mathbf{r}})Y^{m_2}_{j_2}(\hat{\mathbf{r}}) = \sqrt{\frac{2j_1+1}{4\pi}}\sqrt{\frac{2j_2+1}{4\pi}}\mathscr{D}^{j_1}_{0,m_1}\mathscr{D}^{j_2}_{0,m_2}.$$

Applying the Clebsch-Gordan transformation (3.255) to the rotation matrices the product can be written in the form

$$Y^{m_1}_{j_1}(\hat{\mathbf{r}})Y^{m_2}_{j_2}(\hat{\mathbf{r}}) = \sum_{k=|j_1-j_2|}^{j_1+j_2}\sum_{q=-k}^{k}\sqrt{\frac{2j_1+1}{4\pi}}\sqrt{\frac{2j_2+1}{4\pi}}\mathscr{D}^{k}_{0,q}\langle j_1,0;j_2,0|k,0\rangle\langle k,q|j_1,m_1;j_2,m_2\rangle.$$

Recognizing $\mathscr{D}^{k}_{0,q} = \sqrt{4\pi/(2k+1)}Y^{q}_{k}(\hat{\mathbf{r}})$ and expressing the CGCs in terms of $3j$ symbol the product becomes

$$Y^{m_1}_{j_1}(\hat{\mathbf{r}})Y^{m_2}_{j_2}(\hat{\mathbf{r}}) = \sum_{k=|j_1-j_2|}^{j_1+j_2}\sum_{q=-k}^{k}(-1)^q\sqrt{\frac{(2j_1+1)(2j_2+1)(2k+1)}{4\pi}}Y^{q}_{k}(\hat{\mathbf{r}})\begin{pmatrix} j_1 & j_2 & k\\ 0 & 0 & 0\end{pmatrix}\begin{pmatrix} j_1 & j_2 & k\\ m_1 & m_2 & -q\end{pmatrix}.$$

Turning to the integral we can apply on the r.h.s. the orthonormality relation (L.51). Since only the term with $k = j_3$ and $q = -m_3$ is nonzero we arrive at the desired result,

$$\int Y^{m_1}_{j_1}(\hat{\mathbf{r}})Y^{m_2}_{j_2}(\hat{\mathbf{r}})Y^{m_3}_{j_3}(\hat{\mathbf{r}})\,d\hat{\mathbf{r}} = \sqrt{\frac{(2j_1+1)(2j_2+1)(2j_3+1)}{4\pi}}\begin{pmatrix} j_1 & j_2 & j_3\\ 0 & 0 & 0\end{pmatrix}\begin{pmatrix} j_1 & j_2 & j_3\\ m_1 & m_2 & m_3\end{pmatrix}. \qquad \square$$

3.10.4 Composition of spherical tensor operators from vector operators

Specializing Eq. (3.246) to the case $j_1 = j_2 = j = 1$ we can construct spherical tensor operators of rank 0, 1 and 2,

$$T_{3:k,q} \equiv [\mathrm{T}^{(j)}_1 \otimes \mathrm{T}^{(j)}_2]^k_q = (-1)^q\sqrt{(2k+1)}\sum_{m=-1}^{1}T_{1:1,m}T_{2:1,(q-m)}\begin{pmatrix} 1 & 1 & k\\ m & q-m & -q\end{pmatrix}. \tag{3.256}$$

This expression provides the algebraic underpinning of the vector model for the addition of angular momenta as introduced in Section 3.4.1. Denoting the two rank 1 spherical tensor operators (vector operators) by **U** and **V** we can express the standard components of the spherical tensor operators $\mathrm{T}^{(0)}$ (rank 0), $\mathrm{T}^{(1)}$ (rank 1) and $\mathrm{T}^{(2)}$ (rank 2) in terms of the standard components of **U** and **V**:

- *standard* component of $\mathrm{T}^{(0)}$ in terms of the *standard* components of **U** and **V**

$$T_{0,0} = \sqrt{\tfrac{1}{3}}\,(U_{+1}V_{-1} - U_0V_0 + U_{-1}V_{+1}). \tag{3.257}$$

- *standard* components of $\mathrm{T}^{(1)}$ in terms of the *standard* components of **U** and **V**

$$T_{1,0} = \sqrt{\tfrac{1}{2}}\,(U_{+1}V_{-1} - U_{-1}V_{+1}) \tag{3.258a}$$

$$T_{1,\pm} = \pm\sqrt{\tfrac{1}{2}}\,(U_{\pm1}V_0 - U_0V_{\pm1}). \tag{3.258b}$$

- *standard* components of $\mathrm{T}^{(2)}$ in terms of the *standard* components of **U** and **V**

$$T_{2,0} = \sqrt{\tfrac{1}{6}}\,(U_{+1}V_{-1} + 2U_0V_0 + U_{-1}V_{+1}) \tag{3.259a}$$

$$T_{2,\pm1} = \sqrt{\tfrac{1}{2}}\,(U_{\pm1}V_0 + U_0V_{\pm}) \tag{3.259b}$$

$$T_{2,\pm2} = U_{\pm1}V_{\pm1}. \tag{3.259c}$$

Alternatively, using Eq. (3.30) we can express the standard components of **U** and **V** in terms of the cartesian components of **U** and **V**. Using this transformation we obtain an expression for the *standard* components of the spherical tensor operators $\mathrm{T}^{(0)}$, $\mathrm{T}^{(1)}$ and $\mathrm{T}^{(2)}$ in terms of the *cartesian* components of **U** and **V**:

- *standard* component of $\mathrm{T}^{(0)}$ in terms of the *cartesian* components of **U** and **V**

$$T_{0,0} = -\sqrt{\tfrac{1}{3}}\,(U_xV_x + U_yV_y + U_zV_z). \tag{3.260}$$

- *standard* components of $\mathrm{T}^{(1)}$ in terms of the *cartesian* components of **U** and **V**

$$T_{1,0} = i\sqrt{\tfrac{1}{2}}\,(U_xV_y - U_yV_x) \tag{3.261a}$$

$$T_{1,\pm1} = \tfrac{1}{2}\,[(U_zV_x - U_xV_z) \pm i(U_zV_y - U_yV_z)]. \tag{3.261b}$$

- *standard* components of $\mathrm{T}^{(2)}$ in terms of the *cartesian* components of **U** and **V**

$$T_{2,0} = \sqrt{\tfrac{1}{6}}\,(2U_zV_z - U_xV_x - U_yV_y) \tag{3.262a}$$

$$T_{2,\pm1} = \mp\tfrac{1}{2}\,[(U_xV_z + U_zV_x) \pm i(U_yV_z + U_zV_y)] \tag{3.262b}$$

$$T_{2,\pm2} = \tfrac{1}{2}\,[U_xV_x - U_yV_y \pm i(U_xV_y + U_yV_x)]. \tag{3.262c}$$

3.10.5 Composition of cartesian tensor operators from vector operators

Next we turn to the *cartesian* components of the spherical tensors $\mathrm{T}^{(0)}$, $\mathrm{T}^{(1)}$ and $\mathrm{T}^{(2)}$ in terms of the *cartesian* components of **U** and **V**. This offers the possibility to write these tensor components in vector notation

- *cartesian* component of $\mathrm{T}^{(0)}$ in terms of the *cartesian* components of **U** and **V**

$$T_0 = -\sqrt{\tfrac{1}{3}}\,(U_xV_x + U_yV_y + U_zV_z). \tag{3.263}$$

  This shows that, in vector notation, $\mathrm{T}^{(0)}$ can be written as a dot product (i.e., remains invariant under rotation),

$$\mathrm{T}^{(0)} = -\sqrt{\tfrac{1}{3}}\,\mathbf{U}\cdot\mathbf{V}. \tag{3.264}$$

- *cartesian* components of $\mathrm{T}^{(1)}$ in terms of the *cartesian* components of **U** and **V**. Inverting Eqs. (3.261), using Eqs. (K.8), the cartesian components become

$$T_x = i\sqrt{\tfrac{1}{2}}\,(U_yV_z - U_zV_y) \tag{3.265a}$$

$$T_y = -i\sqrt{\tfrac{1}{2}}\,(U_xV_z - U_zV_x) \tag{3.265b}$$

$$T_z = i\sqrt{\tfrac{1}{2}}\,(U_xV_y - U_yV_x). \tag{3.265c}$$

Using the index notation the can be compactly written in the form

$$T_i = i\sqrt{\tfrac{1}{2}}\varepsilon_{ijk}U_jU_k \tag{3.266}$$

which shows that, in vector notation, $\mathrm{T}^{(1)}$ represents a cross product and transforms like a vector,

$$\mathrm{T}^{(1)} = i\sqrt{\tfrac{1}{2}}\begin{vmatrix} \hat{\mathbf{x}} & \hat{\mathbf{y}} & \hat{\mathbf{z}} \\ U_x & U_y & U_z \\ V_x & V_y & V_z \end{vmatrix} = i\sqrt{\tfrac{1}{2}}\,(\mathbf{U}\times\mathbf{V}). \tag{3.267}$$

- *cartesian* components of $T^{(2)}$ in terms of the *cartesian* components of $\mathbf{U}$ and $\mathbf{V}$. In the index notation the reduction of the cartesian components T_{ij} becomes - see Problem 3.25

  $$T_{ij} = U_iV_j = \tfrac{1}{3}\mathbf{U}\cdot\mathbf{V}\delta_{ij} + \tfrac{1}{2}(U_iV_j - U_jV_i) + \tfrac{1}{2}(U_iV_j + U_jV_i) - \tfrac{1}{3}\mathbf{U}\cdot\mathbf{V}\delta_{ij}. \tag{3.268}$$

  This expression shows that T_{ij} (i.e., any 3×3 matrix) can be written as the sum of a diagonal matrix,

  $$\tfrac{1}{3}\mathbf{U}\cdot\mathbf{V}\delta_{ij} \tag{3.269}$$

  (fixed by the trace of the matrix), an antisymmetric matrix,

  $$A_{i,j} = \tfrac{1}{2}(U_iV_j - U_jV_i) \tag{3.270}$$

  (fixed by 3 matrix elements: U_xV_y, U_xV_z and U_yV_z), and a symmetric matrix of zero trace,

  $$S_{i,j} = \tfrac{1}{2}(U_iV_j + U_jV_i) - \tfrac{1}{3}\mathbf{U}\cdot\mathbf{V}\delta_{ij} \tag{3.271}$$

  (fixed by 5 matrix elements, U_xV_y, U_xV_z, U_yV_z, U_xU_y and U_yU_y, with U_zU_z following from the constraint of zero trace).

Problem 3.25. Derive Eq. (3.268), which shows that any 3×3 matrix can be written as the sum of a *diagonal matrix*, an *antisymmetric matrix* and a *zero-trace diagonal matrix.*

Solution. We start from the *inverse decomposition (3.250) for* the case $j_1 = j_2 = j = 1$,

$$T_{1,m_1}T_{1,m_2} = \sum_{k=0}^{2} T_{k,q}(-1)^q\sqrt{2k+1}\begin{pmatrix} 1 & 1 & k \\ m_1 & m_2 & -q \end{pmatrix}\delta_{q,(m_1+m_2)}. \tag{3.272}$$

From this expression we obtain (most conveniently with computer algebra) the reduction of the spherical tensor components $T_{1,m_1}T_{1,m_2} = U_{m_1}V_{m_2}$:

$U_{m_1}V_{m_2}$	V_{+1}	V_0	V_{-1}
U_{+1}	$T_{2,+2}$	$\sqrt{\tfrac{1}{2}}\,(T_{2,+1}+T_{1,+1})$	$\sqrt{\tfrac{1}{6}}\,(T_{2,0}+\sqrt{3}\,T_{1,0}+\sqrt{2}\,T_{0,0})$
U_0	$\sqrt{\tfrac{1}{2}}\,(T_{2,+1}-T_{1,+1})$	$\sqrt{\tfrac{1}{3}}\,(T_{2,0}-\sqrt{2}\,T_{0,0})$	$\sqrt{\tfrac{1}{2}}\,(T_{2,-1}+T_{1,-1})$
U_{-1}	$\sqrt{\tfrac{1}{6}}\,(T_{2,0}-\sqrt{3}\,T_{1,0}+\sqrt{2}\,T_{0,0})$	$\sqrt{\tfrac{1}{2}}\,(T_{2,-1}-T_{1,-1})$	$T_{2,-2}$

To obtain the reduction of the *cartesian* tensor components U_iV_j, with $i,j\in\{x,y,z\}$, we the express the U_iV_j in terms of the $U_{m_1}U_{m_2}$ with the aid of Eqs. (K.8). Subsequently, we substitute for the $T_{k,q}$, the decomposition in terms of the *cartesian* components of $\mathbf{U}$ and $\mathbf{V}$. We demonstrate this explicitly for T_{xx}, T_{xy} and T_{xz} :

$$T_{xx} = U_xV_x = -\sqrt{\tfrac{1}{3}}\,T_{0,0} + \tfrac{1}{2}T_{2,-2} - \sqrt{\tfrac{1}{6}}\,T_{2,0} + \tfrac{1}{2}T_{2,2} = \tfrac{1}{3}\mathbf{U}\cdot\mathbf{V} + U_xU_x - \tfrac{1}{3}\mathbf{U}\cdot\mathbf{V}$$

$$T_{xy} = U_xV_y = -i(\sqrt{\tfrac{1}{2}}\,T_{1,0} - \tfrac{1}{2}T_{2,-2} + \tfrac{1}{2}T_{2,2}) = \tfrac{1}{2}(U_xV_y - U_yV_x) + \tfrac{1}{2}(U_xV_y + U_yV_x)$$

$$T_{xz} = U_xV_z = -\tfrac{1}{2}(T_{1,-1} + T_{1,1} - T_{2,-1} + T_{2,1}) = \tfrac{1}{2}(U_xV_z - U_zV_x) + \tfrac{1}{2}(U_xV_z + UV_x).$$

These results all satisfy the desired expression. □

3.11 Generating angular momentum representations

To demonstrate the procedure for generating representations we discuss a few examples. The unitary matrix $P_z(\varphi)$ for a rotation over an angle φ about the $\hat{\mathbf{z}}$ direction is generated by the operator $e^{-i\varphi J_z/\hbar}$. The matrix representation follows with Eq. (3.224). For the diagonal representation this takes a minimal effort,

$$[P_z(\varphi)]_{m',m} \equiv \langle j,m'|e^{-i\varphi J_z/\hbar}|j,m\rangle = e^{-i\varphi m}\delta_{m',m} \tag{3.273}$$

and using the definition (3.216),

$$J_z = i\hbar \left.\frac{\partial P_z(\varphi)}{\partial\varphi}\right|_{\varphi=0}, \tag{3.274}$$

we obtain

$$[J_z]_{m',m} = m\hbar\delta_{m',m}e^{-i\varphi m}|_{\varphi=0} = m\hbar\delta_{m',m}. \tag{3.275}$$

This could have been written down immediately since

$$[J_z]_{m',m} \equiv \langle j,m'|J_z|j,m\rangle = m\hbar\delta_{m',m}. \tag{3.276}$$

The added value of the formalism becomes evident when asking for the matrix representation of non-diagonal angular momentum operators. For instance, the unitary operator $P_y(\theta)$ corresponds to a physical rotation over an angle θ about the $\hat{\mathbf{y}}$ direction. In this case the matrix representation follows with the Wigner formula,

$$[P_y(\theta)]_{m',m} = \langle j,m'|e^{-i\theta J_y/\hbar}|j,m\rangle = d^j_{m'm}(\theta). \tag{3.277}$$

and

$$\langle j,m'|J_y|j,m\rangle = i\hbar \left.\frac{\partial d^j_{m'm}(\theta)}{\partial\theta}\right|_{\theta=0}. \tag{3.278}$$

3.11.1 Example - the case $j = 1/2$

To demonstrate the procedure for generating representations we first consider the example of angular momentum $j = \frac{1}{2}$ and rederive the results of Section 3.2.3. The unitary matrix $P_z(\varphi)$ for a rotation over an angle φ about the $\hat{\mathbf{z}}$ direction follows with Eq. (3.273). For $j = \frac{1}{2}$ we find

$$P_z(\varphi) = \begin{pmatrix} e^{-i\varphi/2} & 0 \\ 0 & e^{i\varphi/2} \end{pmatrix}. \tag{3.279}$$

To determine J_z we turn to the definition (3.216). First, we calculate the derivative of $P_z(\varphi)$,

$$\left.\frac{\partial P_z(\varphi)}{\partial\varphi}\right|_{\varphi=0} = \begin{pmatrix} -(i/2)e^{-i\varphi/2}|_{\varphi=0} & 0 \\ 0 & (i/2)e^{i\varphi/2}|_{\varphi=0} \end{pmatrix} = -i\begin{pmatrix} 1/2 & 0 \\ 0 & -1/2 \end{pmatrix}. \tag{3.280}$$

Substituting this result into Eq. (3.216) we obtain for the angular momentum operator

$$J_z = i\hbar \left.\frac{\partial P_z(\varphi)}{\partial\varphi}\right|_{\varphi=0} = \tfrac{1}{2}\hbar\begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix}. \tag{3.281}$$

The corresponding eigenvectors are

$$|\uparrow\rangle = \begin{pmatrix} 1 \\ 0 \end{pmatrix}, \quad |\downarrow\rangle = \begin{pmatrix} 0 \\ 1 \end{pmatrix}. \tag{3.282}$$

There are various equivalent ways to proceed. First of all we can use again the method demonstrated for J_z. To determine J_y we start from the unitary operator $P_y(\theta)$, representing a physical rotation over an angle θ about the $\hat{\mathbf{y}}$ direction. For $j = \frac{1}{2}$ the operator $P_y(\theta)$ follows with Eq. (3.277)

$$P_y(\theta) = d^{1/2}_{m'm}(\theta) = \begin{pmatrix} \cos(\theta/2) & -\sin(\theta/2) \\ \sin(\theta/2) & \cos(\theta/2) \end{pmatrix}. \tag{3.283}$$

Using the definition (3.216) we calculate the derivative of $P_z(\varphi)$,

$$\left.\frac{\partial P_y(\theta)}{\partial\theta}\right|_{\theta=0} = \tfrac{1}{2} \begin{pmatrix} -\sin(\theta/2)\,|_{\theta=0} & -\cos(\theta/2)\,|_{\theta=0} \\ \cos(\theta/2)\,|_{\theta=0} & -\sin(\theta/2)\,|_{\theta=0} \end{pmatrix} = \tfrac{1}{2} \begin{pmatrix} 0 & -1 \\ 1 & 0 \end{pmatrix}. \tag{3.284}$$

Substituting this result into Eq. (3.216) we obtain for the angular momentum operator

$$J_y = i\hbar \left.\frac{\partial P_y(\varphi)}{\partial\varphi}\right|_{\varphi=0} = \tfrac{1}{2}\hbar \begin{pmatrix} 0 & -i \\ i & 0 \end{pmatrix}. \tag{3.285}$$

3.11.1.1 Transformation of the cartesian components of J

An alternative approach to obtain J_x and J_y is by unitary transformation of J_z and J_x,

$$J_x = P_y(\pi/2) J_z P_y^\dagger(\pi/2) \tag{3.286a}$$

$$J_y = P_z(\pi/2) J_x P_z^\dagger(\pi/2). \tag{3.286b}$$

The unitary operator $P_z(\varphi)$ corresponds to a physical rotation over an angle φ about the $\hat{\mathbf{z}}$ direction - see Eq. (3.273); for $j = \frac{1}{2}$ it is given by Eq. (3.279). Likewise, the unitary operator $P_y(\theta)$ corresponds to a physical rotation over an angle θ about the $\hat{\mathbf{y}}$ direction - see Eq. (3.277); for $j = \frac{1}{2}$ it is given by Eq. (3.283). Using $\varphi = \pi/2$ in $P_z(\varphi)$ and $\theta = \pi/2$ in $P_y(\theta)$ the unitary operators become

$$P_z(\pi/2) = \sqrt{\tfrac{1}{2}} \begin{pmatrix} 1-i & 0 \\ 0 & 1+i \end{pmatrix}, \quad P_y(\pi/2) = \sqrt{\tfrac{1}{2}} \begin{pmatrix} 1 & -1 \\ 1 & 1 \end{pmatrix}. \tag{3.287}$$

Substituting these expressions into Eqs. (3.286) we find

$$J_x = \tfrac{1}{2}\hbar \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}, \quad J_y = \tfrac{1}{2}\hbar \begin{pmatrix} 0 & -i \\ i & 0 \end{pmatrix}. \tag{3.288}$$

The shift operators follow from the definitions (3.4),

$$J_+ = \hbar \begin{pmatrix} 0 & 1 \\ 0 & 0 \end{pmatrix} \quad \text{and} \quad J_- = \hbar \begin{pmatrix} 0 & 0 \\ 1 & 0 \end{pmatrix}. \tag{3.289}$$

With these expressions we generated the results of Section 3.2.3. The commutation relations (3.1) and (3.7) as well as the shift relations (3.24) are satisfied. Using Eq. (3.9) we calculate $\mathbf{J}^2 = \frac{3}{4}\hbar^2\mathbb{1}$, where $\mathbb{1}$ is the unit matrix. This not only shows that Eq. (3.22a) is satisfied but also that $\mathbf{J}^2$ is invariant under rotation - like any scalar operator (cf. Appendix K). This is not surprising because $\sqrt{\langle\mathbf{J}^2\rangle}$ is a measure for the magnitude of $\mathbf{J}$. Once the matrices for J_y and J_z are known the matrix expressions for $P_z(\varphi) = U_z(-\varphi) = e^{-i\varphi J_z/\hbar}$ and $P_y(\varphi) = U_y(-\varphi) = e^{-i\varphi J_y/\hbar}$ can also be derived by expansion of the exponential operators. This is demonstrated in Problems 3.26 and 3.27.

3.11.1.2 Transformation of the angular momentum eigenstates

As an example we derive some expressions for the eigenstates of the $s = \frac{1}{2}$ system with respect an arbitrary quantization axis starting from the states $|\uparrow\rangle$ and $|\downarrow\rangle$ defined in Eqs. (3.41). A change of the quantization axis from $\hat{\mathbf{z}} = (0,0)$ to $\hat{\mathbf{r}} = (\theta,\phi)$ is realized by a rotation of the coordinate system over the Euler angles $\gamma = 0$, $\beta = -\theta$ and $\alpha = -\phi$. The corresponding unitary transformation is given by

$$\mathscr{D}^{1/2}(\alpha,\beta,\gamma) = P_z(\phi)P_y(\theta)P_z(0). \tag{3.290}$$

Substituting Eqs. (3.279) and (3.283) we obtain

$$\mathscr{D}^{1/2}(\phi,\theta,0) = \begin{pmatrix} e^{-i\phi/2}\cos(\theta/2) & -e^{-i\phi/2}\sin(\theta/2) \\ e^{i\phi/2}\sin(\theta/2) & e^{i\phi/2}\cos(\theta/2) \end{pmatrix}. \tag{3.291}$$

Thus, the spin-up and spin-down states with respect to an arbitrary quantization axis in the $\hat{\mathbf{r}}$ direction are given by

$$|\uparrow\rangle_r = \mathscr{D}^{1/2}(\phi,\theta,0)\,|\uparrow\rangle = e^{-i\phi/2}\begin{pmatrix} \cos(\theta/2) \\ e^{i\phi}\sin(\theta/2) \end{pmatrix} \tag{3.292a}$$

$$|\downarrow\rangle_r = \mathscr{D}^{1/2}(\phi,\theta,0)\,|\downarrow\rangle = e^{-i\phi/2}\begin{pmatrix} -\sin(\theta/2) \\ e^{i\phi}\cos(\theta/2) \end{pmatrix}. \tag{3.292b}$$

Note that with Eq. (3.292a) we regained Eq. (3.61).

Problem 3.26. Show by expansion of the exponential operator $e^{i\alpha S_z/\hbar}$ that the two-dimensional unitary transformation corresponding to a rotation over an angle α about the z axis is given by

$$U_z(\alpha) = \begin{pmatrix} e^{i\alpha/2} & 0 \\ 0 & e^{-i\alpha/2} \end{pmatrix}.$$

Solution. We start with the expansion of the exponential operator,

$$U_z(\alpha) = e^{i\alpha S_z/\hbar} = 1 + i\alpha S_z/\hbar + \frac{1}{2!}(i\alpha S_z/\hbar)^2 + \frac{1}{3!}(i\alpha S_z/\hbar)^3 + \cdots.$$

The even and the odd terms can be factorized in a form containing a common matrix,

$$(i\alpha S_z/\hbar)^{2n} = (i\alpha/2)^{2n}\begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix}; \qquad (i\alpha S_z/\hbar)^{2n+1} = (i\alpha/2)^{2n+1}\begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix}.$$

Next we recall the expansions of the sine and the cosine,

$$\begin{aligned}\cos\varphi &= \sum_{n=0}^{\infty}\frac{(-1)^n}{2n!}\varphi^{2n} = \sum_{n=0}^{\infty}\frac{(i\varphi)^{2n}}{2n!}\\ i\sin\varphi &= \sum_{n=0}^{\infty}\frac{i\,(-1)^n}{(2n+1)!}\varphi^{2n+1} = \sum_{n=0}^{\infty}\frac{(i\varphi)^{2n+1}}{(2n+1)!}.\end{aligned}$$

Summing the even and odd terms separately we obtain

$$U_z(\alpha) = \cos(\alpha/2)\begin{pmatrix}1 & 0\\ 0 & 1\end{pmatrix} + i\sin(\alpha/2)\begin{pmatrix}1 & 0\\ 0 & -1\end{pmatrix}.$$

Using the relation $e^{i\varphi} = \cos\varphi + i\sin\varphi$ we arrive at the desired expression. □

Problem 3.27. Show by expansion of the exponential operator $e^{i\beta S_y/\hbar}$ that the two-dimensional unitary transformation corresponding to a rotation over an angle β about the y axis is given by

$$U_y(\beta) = \begin{pmatrix}\cos(\beta/2) & \sin(\beta/2)\\ -\sin(\beta/2) & \cos(\beta/2)\end{pmatrix}.$$

Solution. The proof goes along the same lines as in Problem 3.21. We start with the expansion of the exponential operator. In the present case the even and the odd terms factorize differently in the following way,

$$(i\beta S_y/\hbar)^{2n} = (i\beta/2)^{2n}\begin{pmatrix}1 & 0\\ 0 & 1\end{pmatrix};\qquad (i\beta S_y/\hbar)^{2n+1} = (i\beta/2)^{2n+1}\begin{pmatrix}0 & -i\\ i & 0\end{pmatrix}.$$

Recalling the expansions of the sine and cosine we obtain after summing over the even and odd terms

$$U_y(\beta) = \cos\beta/2\begin{pmatrix}1 & 0\\ 0 & 1\end{pmatrix} + \sin\beta/2\begin{pmatrix}0 & 1\\ -1 & 0\end{pmatrix}.$$

Adding the two contributions we arrive at the desired expression. □

3.11.2 Example: $l = 1$ orbital angular momentum

To demonstrate the procedure for generating representations we consider the example of $l = 1$ orbital angular momentum and rederive Eq. (3.32). The unitary matrix $P_z(\varphi)$ is generated by the operator $e^{-i\varphi L_z/\hbar}$. The matrix elements follow with Eq. (3.224),

$$[P_z(\varphi)]_{m',m} = \langle l, m'|e^{-i\varphi L_z/\hbar}|l, m\rangle = \begin{cases} e^{-i\varphi m/\hbar} & \text{for } m' = m\\ 0 & \text{for } m' \neq m.\end{cases} \tag{3.293}$$

For $l = 1$ we obtain

$$P_z(\varphi) = \begin{pmatrix} e^{-i\varphi} & 0 & 0\\ 0 & 1 & 0\\ 0 & 0 & e^{i\varphi}\end{pmatrix}. \tag{3.294}$$

To determine L_z we turn to the definition (3.216). First, we calculate the derivative of $P_z(\varphi)$,

$$\left.\frac{\partial P_z(\varphi)}{\partial\varphi}\right|_{\varphi=0} = \begin{pmatrix} -ie^{-i\varphi}|_{\varphi=0} & 0 & 0 \\ 0 & 0 & 0 \\ 0 & 0 & ie^{i\varphi}|_{\varphi=0} \end{pmatrix} = -i \begin{pmatrix} 1 & 0 & 0 \\ 0 & 0 & 0 \\ 0 & 0 & -1 \end{pmatrix}. \tag{3.295}$$

Substituting this result into Eq. (3.216) we obtain for the angular momentum operator

$$L_z = i\hbar \left.\frac{\partial P_z(\varphi)}{\partial\varphi}\right|_{\varphi=0} = \hbar \begin{pmatrix} 1 & 0 & 0 \\ 0 & 0 & 0 \\ 0 & 0 & -1 \end{pmatrix}. \tag{3.296}$$

This is indeed the expression given by Eq. (3.32).

The unitary matrix $P_y(\varphi)$ is generated by the operator $e^{-i\varphi L_y/\hbar}$. The matrix elements follow with Eq. (3.224),

$$[P_y(\theta)]_{m',m} = \langle j, m'|e^{-i\theta J_y/\hbar}|j, m\rangle = d^j_{m'm}(\theta). \tag{3.297}$$

For $l = 1$ we obtain

$$P_y(\theta) = \begin{pmatrix} \frac{1}{2}(1+\cos\theta) & -\sqrt{\frac{1}{2}}\sin\theta & \frac{1}{2}(1-\cos\theta) \\ \sqrt{\frac{1}{2}}\sin\theta & \cos\theta & -\sqrt{\frac{1}{2}}\sin\theta \\ \frac{1}{2}(1-\cos\theta) & \sqrt{\frac{1}{2}}\sin\theta & \frac{1}{2}(1+\cos\theta) \end{pmatrix}. \tag{3.298}$$

To determine L_y we use the definition (3.216). First, we calculate the derivative of $P_y(\theta)$,

$$\left.\frac{\partial P_y(\theta)}{\partial\theta}\right|_{\theta=0} = \begin{pmatrix} -\frac{1}{2}\sin\theta|_{\theta=0} & -\sqrt{\frac{1}{2}}\cos\theta|_{\theta=0} & \frac{1}{2}\sin\theta|_{\theta=0} \\ \sqrt{\frac{1}{2}}\cos\theta|_{\theta=0} & -\sin\theta|_{\theta=0} & -\sqrt{\frac{1}{2}}\cos\theta|_{\theta=0} \\ \frac{1}{2}\sin\theta|_{\theta=0} & \sqrt{\frac{1}{2}}\cos\theta|_{\theta=0} & -\frac{1}{2}\sin\theta|_{\theta=0} \end{pmatrix} = \sqrt{\tfrac{1}{2}} \begin{pmatrix} 0 & -1 & 0 \\ 1 & 0 & -1 \\ 0 & 1 & 0 \end{pmatrix}. \tag{3.299}$$

Substituting this result into Eq. (3.216) we obtain for the angular momentum operator

$$L_y = i\hbar \left.\frac{\partial P_y(\theta)}{\partial\theta}\right|_{\theta=0} = \sqrt{\tfrac{1}{2}}\hbar \begin{pmatrix} 0 & -i & 0 \\ i & 0 & -i \\ 0 & i & 0 \end{pmatrix}. \tag{3.300}$$

Note that this is the expression given in Eq. (3.34).

3.11.2.1 Transformation of the angular momentum eigenstates

As an example we derive some expressions for the eigenstates of the $l = 1$ system with respect an arbitrary quantization axis starting from the state $|1,1\rangle \equiv |1,1\rangle_z$ defined in Eqs. (3.31). A change of the quantization axis from $\hat{\mathbf{z}} = (0,0)$ to $\hat{\mathbf{r}} = (\theta,\phi)$ is realized by a rotation of the coordinate system over the Euler angles $\gamma = 0$, $\beta = -\theta$ and $\alpha = -\phi$. The corresponding unitary transformation is given by

$$\mathscr{D}^1(\alpha,\beta,\gamma) = P_z(\phi)P_y(\theta)P_z(0). \tag{3.301}$$

Substituting Eqs. (3.294) and (3.298) we obtain

$$\mathscr{D}^1(\phi,\theta,0)=\begin{pmatrix}\frac{1}{2}(1+\cos\theta)e^{-i\varphi} & -\sqrt{\frac{1}{2}}\sin\theta e^{-i\varphi} & \frac{1}{2}(1-\cos\theta)e^{-i\varphi}\\ \sqrt{\frac{1}{2}}\sin\theta & \cos\theta & -\sqrt{\frac{1}{2}}\sin\theta\\ \frac{1}{2}(1-\cos\theta)e^{i\varphi} & \sqrt{\frac{1}{2}}\sin\theta e^{i\varphi} & \frac{1}{2}(1+\cos\theta)e^{i\varphi}\end{pmatrix}. \tag{3.302}$$

Hence, by unitary transformation we find $|1,1\rangle_x$ and $|1,1\rangle_y$

$$|1,1\rangle_x=\mathscr{D}^1(0,\pi/2,0\,|1,1\rangle=\frac{1}{2}\begin{pmatrix}1 & -\sqrt{2} & 1\\ \sqrt{2} & 0 & -\sqrt{2}\\ 1 & \sqrt{2} & 1\end{pmatrix}\begin{pmatrix}1\\0\\0\end{pmatrix}=\frac{1}{2}\begin{pmatrix}1\\ \sqrt{2}\\ 1\end{pmatrix} \tag{3.303a}$$

$$|1,1\rangle_y=\mathscr{D}^1(\pi/2,\pi/2,0)\,|1,1\rangle=\frac{1}{2}\begin{pmatrix}-i & i\sqrt{2} & -i\\ \sqrt{2} & 0 & -\sqrt{2}\\ i & i\sqrt{2} & i\end{pmatrix}\begin{pmatrix}1\\0\\0\end{pmatrix}=\frac{1}{2}\begin{pmatrix}-i\\ \sqrt{2}\\ i\end{pmatrix}. \tag{3.303b}$$

The corresponding density matrices are $\rho_{|1,1\rangle_x}$and $\rho_{|1,1\rangle_y}$ follow directly from these expressions

$$\rho_{|1,1\rangle_x}=\frac{1}{4}\begin{pmatrix}1 & \sqrt{2} & 1\\ \sqrt{2} & 2 & \sqrt{2}\\ 1 & \sqrt{2} & 1\end{pmatrix}\quad\text{and}\quad\rho_{|1,1\rangle_y}=\frac{1}{4}\begin{pmatrix}1 & -i\sqrt{2} & -1\\ i\sqrt{2} & 2 & -i\sqrt{2}\\ -1 & i\sqrt{2} & 1\end{pmatrix}. \tag{3.304}$$

Note that these density matrices are idempotent and have unit trace as required for pure states.

3.11.2.2 Transformation of the cartesian components of J

An alternative approach to obtain J_x and J_y is by unitary transformation of J_z and J_x,

$$J_x=P_y(\pi/2)J_zP_y^\dagger(\pi/2) \tag{3.305a}$$

$$J_y=P_z(\pi/2)J_xP_z^\dagger(\pi/2). \tag{3.305b}$$

The unitary operator $P_z(\varphi)$ corresponds to a physical rotation over an angle φ about the $\hat{\mathbf{z}}$ direction - see Eq. (3.273); for $j=1$ it is given by Eq. (3.294). Likewise, the unitary operator $P_y(\theta)$ corresponds to a physical rotation over an angle θ about the $\hat{\mathbf{y}}$ direction - see Eq. (3.297); for $j=1$ it is given by Eq. (3.298). Using $\varphi=\pi/2$ in $P_z(\varphi)$ and $\theta=\pi/2$ in $P_y(\theta)$ the unitary operators become

$$P_z(\pi/2)=\begin{pmatrix}-i & 0 & 0\\ 0 & 1 & 0\\ 0 & 0 & i\end{pmatrix},\quad P_y(\pi/2)=\frac{1}{2}\begin{pmatrix}1 & -\sqrt{2} & 1\\ \sqrt{2} & 0 & -\sqrt{2}\\ 1 & \sqrt{2} & 1\end{pmatrix}. \tag{3.306}$$

Substituting these expressions into Eqs. (3.305) we find

$$J_x=\sqrt{\tfrac{1}{2}}\hbar\begin{pmatrix}0 & 1 & 0\\ 1 & 0 & 1\\ 0 & 1 & 0\end{pmatrix},\quad J_y=\sqrt{\tfrac{1}{2}}\hbar\begin{pmatrix}0 & -i & 0\\ i & 0 & -i\\ 0 & i & 0\end{pmatrix}. \tag{3.307}$$

The shift operators follow from the definitions (3.4),

$$J_+ = \sqrt{2}\hbar \begin{pmatrix} 0 & 1 & 0 \\ 0 & 0 & 1 \\ 0 & 0 & 0 \end{pmatrix} \quad \text{and} \quad J_- = \sqrt{2}\hbar \begin{pmatrix} 0 & 0 & 0 \\ 1 & 0 & 0 \\ 0 & 1 & 0 \end{pmatrix}. \tag{3.308}$$

With these expressions we generated the results of Section 3.2.1.

4

Fine Structure

In Chapter 2 we introduced the term *fine structure* for small deviations from the principal atomic structure. The deviation from the Bohr formula can be a small shift or involve the splitting of an energy level. A common feature is that the shift or splitting is much smaller than the separation from adjacent Bohr levels. Interestingly, fine-structure splittings were already recorded a century before the Bohr formula was derived. In 1814 Joseph von Fraunhofer studied the solar spectrum and noted the famous doublet splitting of the D lines of *sodium* (Na) at 589.5 nm [45]. We shall find that in the alkali elements this splitting arises from slight differences in screening of the nuclear charge by the core electrons (see Section 4.5).

The fine structure of atomic hydrogen has a completely different origin. Revealing this origin has been one of the great puzzles of modern physics - competing phenomena had to be unraveled and important new physics had to be discovered. The first step was made by Arnold Sommerfeld, who showed in 1916 that relativistic correction of the kinetic energy gives rise to a doublet splitting of the correct order of magnitude [104]. A rigorous relativistic description was possible only after Paul Dirac formulated his relativistic quantum theory for the electron in 1928 [33]. In this theory the appearance of spin and the associated magnetic moment were identified as intrinsic relativistic phenomena. Aside from *relativistic* corrections also *radiative* corrections are essential to explain the detailed fine structure of the hydrogen atom. In 1947 Willis Lamb and Robert Retherford measured a small shift between the $2s$ and $2p$ level in hydrogen that could not be explained by the Dirac theory [68]. In the same year Hans Bethe demonstrated that this so-called *Lamb shift* arises from the zero-point fluctuations of the quantized electromagnetic field [13]. This has been one of the key ingredients that led to the formulation of modern *quantum electrodynamics* (QED) in which relativistic quantum mechanics and electrodynamics are unified in a single theory.

Unfortunately, both the Dirac theory and QED fall outside the scope of this introductory course. We adopt the phenomenological point of view in which the consequences of the Dirac theory (like spin) are postulated. This has the advantage that the elements of atomic spectroscopy can be introduced without facing the full complexity of the atom at once. Following the historical sequence of events we introduce the relativistic corrections to the kinetic and potential energy of the electrons and discuss the properties of spin as well as the origin of spin-orbit coupling. This phenomenological approach can be justified as being a mapping of the Dirac theory onto an effective Hamiltonian which can be evaluated with perturbation theory.

Atoms consist of orbiting and spinning charges. Therefore, it is not surprising that these ingredients affect the atomic structure at the fundamental level. They manifest themselves as classical and non-classical forms of magnetism. The best known magnetic phenomenon is the splitting of spectral lines by an applied magnetic field. This was discovered by Pieter Zeeman in 1897 and known as the *Zeeman effect* [125]. In zero field, the electronic magnetism manifests itself in spin-orbit splitting. The importance of magnetic interactions reaches far beyond atomic physics into condensed matter physics and chemistry. Magnetic interactions between atoms are crucial for the understanding of molecular binding and cohesion in solids and find important applications, for instance in medical imaging. Interestingly, although decisive for major applications, in atomic physics magnetic interactions appear as weak perturbations of the principal atomic structure.

In the coming sections we introduce the atomic fine structure of *one-electron atoms.*. We start with hydrogenic atoms and identify four contributions to the level shift (see Fig. 4.1). We distinguish between orbital- and spin-related coupling to magnetic fields (Sections 4.1-4.2). The spin and orbital dynamics are combined in spin-orbit coupling (Section 4.5). This is a velocity-induced phenomenon and embodies the central issue of the chapter. We discuss how, in hydrogenic atoms, the various shifts enter on equal footing (Section 4.5), whereas in alkali-like atoms the spin-orbit shift dominates the physics (Section 4.6). This is explained by the role of core electrons which effectively screen the valence electron from the nuclear charge. The last section of the chapter deals with the competition between spin-orbit and Zeeman coupling (Section 4.7).

4.1 Relativistic and radiative shifts

4.1.1 Relativistic mass correction

Close to the nucleus the electrons are accelerated to relativistic velocities. This gives rise to lifting of the degeneracy of energy levels of different l but equal n. The relativistic shifts are small but comparable to the Zeeman splitting. The *relativistic Hamiltonian* of a spinless particle of rest mass m moving in a central field $\mathcal{V}(r)$ is given by

$$H = \sqrt{c^2\mathbf{p}^2 + m^2c^4} + \mathcal{V}(r). \tag{4.1}$$

Subtracting the rest energy mc^2 and the potential energy $\mathcal{V}(r)$ we obtain the kinetic energy T, which can be expanded in even powers of v/c,

$$\begin{aligned} T &= \sqrt{c^2\mathbf{p}^2 + m^2c^4} - mc^2 = mc^2\sqrt{1 + (\frac{\mathbf{v}}{c})^2} - mc^2 \\ &= \left[1 + \tfrac{1}{2}(\frac{\mathbf{v}}{c})^2 - \tfrac{1}{8}(\frac{\mathbf{v}}{c})^4 + \cdots - 1\right] mc^2 \\ &= \frac{\mathbf{p}^2}{2m} - \frac{1}{2mc^2}\left(\frac{\mathbf{p}^2}{2m}\right)^2 + \cdots]. \end{aligned} \tag{4.2}$$

The second line shows how the mass of the moving body depends on v/c. For weakly relativistic velocities the expansion (4.2) can be used to calculate the *relativistic correction* to the kinetic energy by perturbation theory. In particular, using the reduced mass m_r of the electron in a hydrogenic atom we can write the atomic Hamiltonian in the form (H.1)

$$\mathcal{H} - m_rc^2 = T + \mathcal{V}(r) = \frac{\mathbf{p}^2}{2m_r} + \mathcal{V}(r) + \mathcal{H}_r^{\mathrm{mass}} = \mathcal{H}_0 + \mathcal{H}_r^{\mathrm{mass}}, \tag{4.3}$$

where $\mathcal{H}_0$ is the (non-relativistic) Schrödinger Hamiltonian (2.1) with eigenstates $R_{nl}(r)$ given by Eq. (2.37). The perturbation $\mathcal{H}_r^{\mathrm{mass}}$ can be expressed in terms of $\mathcal{H}_0$ and $\mathcal{V}(r)$

$$\mathcal{H}_r^{\mathrm{mass}} = -\frac{1}{2m_rc^2}\left(\frac{\mathbf{p}^2}{2m_r}\right)^2 = -\frac{1}{2m_rc^2}\left(\frac{p_r^2}{2m_r} + \frac{\mathbf{L}^2}{2m_rr^2}\right)^2 = -\frac{1}{2m_rc^2}\left[\mathcal{H}_0 - \mathcal{V}(r)\right]^2. \tag{4.4}$$

We now calculate the splitting of the Bohr level n by the relativistic mass correction. Since $\mathcal{H}_r^{\mathrm{mass}}$ commutes with $\mathbf{L}^2$ and L_z, the relativistic mass correction is *diagonal* in the rotational basis $\{|lm_l\rangle\}$; i.e., l and m_l are “good” quantum numbers. This makes explicit diagonalization of the perturbation matrix superfluous and reveals the rotational basis as the *optimal basis* to evaluate the perturbation

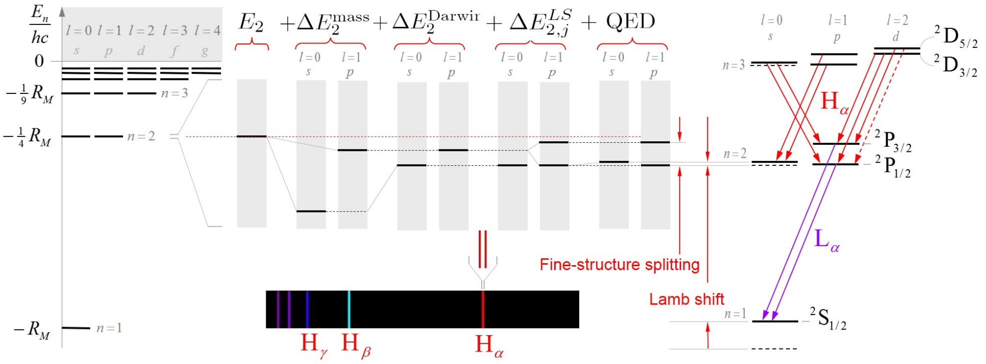

Figure 4.1: Fine-structure effects in hydrogenic atoms. From left to right are shown the unperturbed level at $E_2 = -\frac{1}{4}R_M$ and the cumulative effects of subsequently the relativistic mass correction shift ΔE_2^{mass}, the Darwin shift ΔE_2^{D}, the spin-orbit shifts $\Delta E_{2,j}^{LS}$ for $j = l \pm \frac{1}{2}$ and the Lamb shift. The latter cannot be understood with classical fields but requires quantum electrodynamics (QED). On the far right the Balmer transitions are shown. The dashed line is forbidden as a single photon electric-dipole transition.

(see Appendix H.3). Although states of different n are coupled by the perturbation ($\mathcal{H}_r^{\text{mass}}$ does *not* commute with $\mathcal{H}_0$) this is of no consequence as long as the second order correction is negligible (n is a "good quantum number to first order in perturbation theory"). The latter is satisfied as long as the first-order shifts are small in comparison to the level separation of the principal structure. Under these conditions the level shifts can be calculated in hydrogenic basis, $\{|nlm_l\rangle\}$, using the well-known expression from ordinary first-order perturbation theory - see Appendix H.3.1

$$\Delta E_{nlm}^{\text{mass}} = \langle nlm_l|\mathcal{H}_r^{\text{mass}}|nlm_l\rangle. \tag{4.5}$$

Using the hermiticity of $\mathcal{H}_0$ as well as the eigenvalues of the Schrödinger Hamiltonian we obtain

$$\begin{aligned}\Delta E_{nlm_l}^{\text{mass}} &= -\frac{1}{2m_rc^2}\langle nlm_l|\,[\mathcal{H}_0 - \mathcal{V}(r)]^2\,|nlm_l\rangle & (4.6)\\ &= -\frac{1}{2m_rc^2}[E_n^2 - 2E_n\langle nlm_l|\mathcal{V}(r)|nlm_l\rangle + \langle nlm_l|\mathcal{V}^2(r)|nlm_l\rangle]. & (4.7)\end{aligned}$$

Let us evaluate the relativistic shift $\Delta E_{nlm_l}^{\text{mass}}$ for hydrogenic atoms. Using the radial wavefunctions given in Section 2.3 we find that the shift is independent of the quantum number m_l. After integration over the angles θ and ϕ it takes the form

$$\Delta E_{nl}^{\text{mass}} = -\frac{1}{2m_rc^2}\left[E_n^2 - 2E_n\int_0^\infty \mathcal{V}(r)R_{nl}^2(r)r^2dr + \int_0^\infty \mathcal{V}^2(r)R_{nl}^2(r)r^2dr\right]. \tag{4.8}$$

Before evaluating the integral we note that the electrostatic interaction can be expressed in terms of the fine-structure constant α, $\mathcal{V}(r) = -(e^2/4\pi\varepsilon_0)Z/r = -\alpha^2 m_rc^2 Za/r$. Then, using Eq. (2.33) for E_n and Eqs. (2.49) for $\langle 1/\rho\rangle$ and $\left\langle 1/\rho^2\right\rangle$ we obtain

$$\begin{aligned}\Delta E_n^{\text{mass}} &= -E_n\frac{E_n}{2m_rc^2}[1 + 2\alpha^2m_rc^2Z/E_n\,\langle 1/\rho\rangle + \left(\alpha^2m_rc^2Z/E_n\right)^2\left\langle 1/\rho^2\right\rangle]\\ &= E_n\frac{\alpha^2Z^2}{4n^2}\left[1 - 2\frac{2n^2}{Z}\frac{Z}{n^2} + \left(\frac{2n^2}{Z}\right)^2\frac{Z^2}{n^3}\frac{1}{l+1/2}\right]\\ &= -E_n\frac{\alpha^2Z^2}{n^2}\left(\frac{3}{4} - \frac{n}{l+1/2}\right). \end{aligned}\tag{4.9}$$

This is a celebrated result - obtained by Arnold Sommerfeld in 1916 [104]. Note that it validates our use of first-order perturbation theory because the shifts are small compared to the level spacing of the principal structure, $\Delta E_n^{\text{mass}}/E_n \approx \alpha^2$. More interestingly, it shows that the relativistic corrections depend on the orbital angular momentum quantum number l and are biggest for states with low l. This l dependence lifts the accidental degeneracy of states with different angular momentum (see Fig. 4.1). Physically this is to be expected: the smaller the value of l, the closer the electron approaches the nucleus, the faster the motion and the larger the relativistic shift.

4.1.2 Darwin term

The relativistic velocity of the electron close to the nucleus also affects the Coulomb interaction. It turns out that under weakly relativistic conditions the Dirac equation can be reduced to a Schrödinger-type equation in which the effective Coulomb interaction is weaker. This is expressed by a correction term in the effective Hamiltonian known as the *Darwin term*,

$$\mathcal{H}_r^{\text{Darwin}} = \frac{e\hbar^2}{8m_e^2c^2}\text{div}\mathbf{E}. \tag{4.10}$$

The Darwin term has no classical analogue but it can be made plausible. The Dirac theory has the property that relativistic electrons exhibit a rapid quiver motion called *Zitterbewegung* [100, 51] over distances of the order of the (reduced) *Compton wavelength,* $\lambda_C = \hbar/m_e c = \alpha a_0 \simeq 3.86 \times 10^{-13}$ m. This length is a factor α smaller than the Bohr radius, $a_0 \simeq 5.29 \times 10^{-11}$ m, but much larger than the proton rms charge radius $r_p \simeq 8.78 \times 10^{-16}$ m. If we postulate this Zitterbewegung we can estimate the magnitude of the Darwin term by heuristically delocalizing the electron presuming a centrally symmetric charge distribution $\varrho(r')$ of size of the Compton wavelength and normalized to the total charge, $\int \varrho(r')d\mathbf{r}' = -e$. In this model an effective electrostatic energy is obtained by averaging over the charge distribution. For a nucleus of charge Ze at position $\mathbf{r}$ the average is given by

$$\mathcal{V}(\mathbf{r}) = Ze\int \varrho(r')\varphi(\mathbf{r}-\mathbf{r}')d\mathbf{r}'. \tag{4.11}$$

Here

$$\varphi(\mathbf{r}-\mathbf{r}') = \frac{1}{4\pi\varepsilon_0}\frac{1}{|\mathbf{r}-\mathbf{r}'|} \tag{4.12}$$

is a *nonlocal* scalar potential, nonlocal because the electron is delocalized as is accounted for by integrating over the dummy variable $\mathbf{r}'$. Obviously, the model cannot provide more than an order of magnitude estimate. So, we simply model the electron as a homogeneously charged sphere of radius R, with the charge density given by

$$\varrho(r') = \varrho_0 = -\frac{3e}{4\pi R^3}. \tag{4.13}$$

To evaluate the integral we choose $\mathbf{r}$ and $\mathbf{r}'$ relative to the center of the charge distribution as illustrated in Fig. 4.2. Using the multipole expansion (L.41) we find with the aid of the orthogonality relation for Legendre polynomials (L.45) that for a spherical charge distribution *only the* $l = 0$ *contribution is nonvanishing* and obtain for the electrostatic potential (see Problem 4.1)[1]

$$\varphi(r) = -\frac{1}{4\pi\varepsilon_0}\frac{e}{r} - \frac{1}{4\pi\varepsilon_0}\frac{e}{2R}\left[3 - \left(\frac{r}{R}\right)^2 - 2\frac{R}{r}\right]_{r<R}. \tag{4.14}$$

To obtain the Darwin term we rewrite the potential energy in a form introducing a short-range correction to the pure Coulomb law

$$\mathcal{V}(r) = Ze\varphi(\mathbf{r}) = -\frac{Ze^2}{4\pi\varepsilon_0}\frac{1}{r} + \mathcal{V}'(r). \tag{4.15}$$

---

[1] Nonspherical nuclei are discussed in Chapter 6.

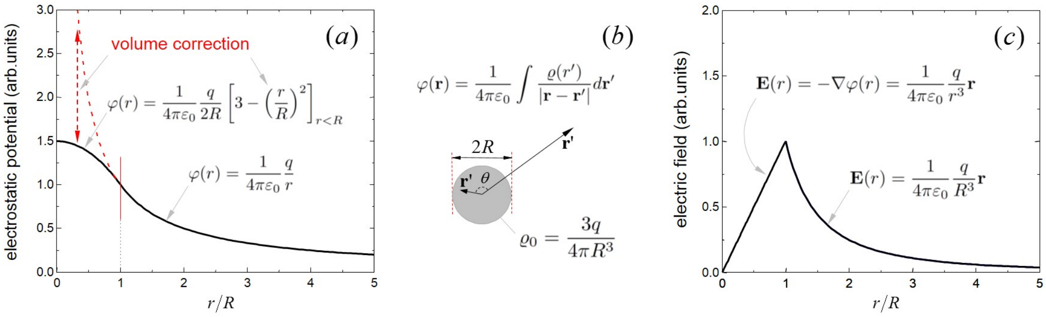

Figure 4.2: Electrostatic scalar potential (see a) and electric field (see c) of a homogeneously charged solid sphere of total charge q and radius R (see c). The dashed vertical arrow shows how the electrostatic potential can be obtained by correcting the Coulomb law for distances $r \leq R$.

Comparing Eqs. (4.14) and (4.15) we find that the correction is given by

$$\mathcal{V}'(r)=-\frac{Ze^2}{4\pi\varepsilon_0}\frac{1}{2R}\left(3-\frac{r^2}{R^2}-\frac{2R}{r}\right)\qquad\text{for } r\leq R. \tag{4.16}$$

We calculate the Darwin correction of the Bohr level n in the same way as the relativistic mass correction. We use ordinary first-order perturbation theory in the hydrogenic basis $\{|nlm_l\rangle\}$,

$$\Delta E_n^{\text{Darwin}}=\langle nlm_l|\mathcal{V}'(r)|nlm_l\rangle. \tag{4.17}$$

Since $\mathcal{V}'(r)$ commutes with $\mathbf{L}^2$ and L_z this perturbation is *diagonal* in the rotational basis $\{|lm_l\rangle\}$; i.e., l and m_l are "good" quantum numbers. Since $\mathcal{V}'(r)$ does *not* commute with $\mathcal{H}_0$, states of different n are coupled by the perturbation but this is of no consequence as long as the second-order shift is negligible (n is a "good quantum number to first order in perturbation theory" - see Appendix H.3). In the position representation we find

$$\Delta E^{\text{Darwin}}\simeq-\frac{Ze^2}{4\pi\varepsilon_0}\frac{1}{2R}\int\left(3-\frac{r^2}{R^2}-\frac{2R}{r}\right)R_{nl}^2(r)|Y_l^{m_l}(\hat{\mathbf{r}})|^2d\mathbf{r}\qquad\text{with } r\leq R. \tag{4.18}$$

Since $\mathcal{V}'(r)$ has central symmetry the angular part evaluates to unity. Since $r\leq R\ll a_0$ the radial wavefunction can be replaced by its value in the origin and the Darwin correction is given by

$$\Delta E^{\text{Darwin}}\simeq-\frac{Ze^2}{4\pi\varepsilon_0}\frac{1}{2R}R_{nl}^2(0)\int_0^R\left(3-\frac{r^2}{R^2}-\frac{2R}{r}\right)r^2dr=\frac{Ze^2}{4\pi\varepsilon_0}\frac{R^2}{10}R_{nl}^2(0). \tag{4.19}$$

Importantly, this expression shows that the Darwin shift *only affects s states* because for nonzero angular momentum the radial wavefunction vanishes in the origin (see Fig. 2.2). The result (4.19) can also be obtained by using the concept of a *contact interaction*; i.e., an interaction for which the strength scales with the probability density of the electronic wavefunction at the position of the nucleus. Note that by including the following contact interaction directly into the Hamiltonian

$$\mathcal{H}_r^{\text{Darwin}}\simeq\frac{Ze^2}{\varepsilon_0}\frac{R^2}{10}\delta(\mathbf{r}) \tag{4.20}$$

we regain the Darwin shift (4.19) after averaging over the electronic wavefunction.[1] With insider knowledge of Eq. (4.10) we choose $R^2/10=\lambda_C^2/8$ and obtain

$$\mathcal{H}_r^{\text{Darwin}}=\frac{Ze^2}{\varepsilon_0}\frac{\hbar^2}{8m_e^2c^2}\delta(\mathbf{r}). \tag{4.21}$$

---

[1] Note the relation $\delta(r)=4\pi\delta(\mathbf{r})r^2$.

This results also follows directly from Eq. (4.10). In the Dirac theory the electron is point like and its Coulomb potential in the field of the nuclear charge given by $\varphi(r) = Ze/4\pi\varepsilon_0 r$. Since $\mathbf{E} = -\nabla\varphi$ and $\Delta 1/r = -4\pi\delta(\mathbf{r})$ the Darwin term (4.10) takes the form (4.21).

To conclude the section we calculate the total relativistic correction. For the Darwin correction we use $\hbar/m_e c = \alpha a_0$ and recalling Eq. (2.39) for the radial wavefunction in the origin we obtain

$$\Delta E^{\text{Darwin}} = \frac{1}{4\pi\varepsilon_0}\frac{e^2}{a_0}\frac{Z^2}{2n^2}\frac{\alpha^2 Z^2}{n^2}n = -E_n\frac{\alpha^2 Z^2}{n^2}n. \tag{4.22}$$

Combining the two relativistic corrections

$$\mathcal{H}_r = \mathcal{H}_r^{\text{mass}} + \mathcal{H}_r^{\text{Darwin}}, \tag{4.23}$$

we obtain the total relativistic shift

$$\Delta E_n^{\text{rel}} = \Delta E_n^{\text{mass}} + \Delta E_n^{\text{Darwin}} = \begin{cases} -E_n\dfrac{\alpha^2 Z^2}{n^2}\left(\dfrac{3}{4} - \dfrac{n}{l+1/2}\right) & \text{for } l > 0 \\ -E_n\dfrac{\alpha^2 Z^2}{n^2}\left(\dfrac{3}{4} - n\right) & \text{for } l = 0. \end{cases} \tag{4.24}$$

The relativistic splitting between the nl and ns levels is given by

$$\Delta E_{nl-ns}^{\text{rel}} = \frac{\alpha^2 Z^2}{n^3}\left(\frac{2l-1}{2l+1}\right)\text{Ry} \tag{4.25}$$

In atomic hydrogen the relativistic splitting between the $2p$ and $2s$ levels is $\Delta E_{2p-2s}^{\text{rel}} = 7.296\,\text{GHz}$. As we shall see in the coming sections the relativistic corrections discussed here are of the same order of magnitude as typical magnetic corrections.

Problem 4.1. Show that for a homogeneously charged sphere (radius R, total charge q) the electrostatic potential can be written as the sum of a pure Coulomb potential plus a correction term for distances $r < R$,

$$\varphi(r) = \frac{1}{4\pi\varepsilon_0}\frac{q}{r} + \frac{1}{4\pi\varepsilon_0}\frac{q}{2R}\left[3 - \left(\frac{r}{R}\right)^2 - 2\frac{R}{r}\right]_{r<R}.$$

Solution. The electrostatic potential is given by

$$\varphi(\mathbf{r}) = \frac{1}{4\pi\varepsilon_0}\int\frac{\varrho(r')}{|\mathbf{r}-\mathbf{r}'|}d\mathbf{r}'.$$

For a homogeneously charged sphere of total charge q the charge density is $\varrho_0 = 3q/4\pi R^3$. As the charge distribution is spherical we can evaluate the integral by restricting ourselves to the first term of the multipole expansion (L.41). Thus, we obtain

$$\int\frac{\varrho(r')}{r_>}d\mathbf{r}' = \begin{cases} \dfrac{\varrho_0}{r}\displaystyle\int_0^r 4\pi r'^2 dr' + \varrho_0 4\pi r' dr' = \dfrac{q}{2R}\left[3 - \left(\dfrac{r}{R}\right)^2\right] & r < R \\ \dfrac{\varrho_0}{r}\displaystyle\int_0^R 4\pi r'^2 dr' = \dfrac{q}{r} & r \geq R, \end{cases}$$

where $r_> = \max\{r, r'\}$. Adding and subtracting q/r for distances $r < R$ we obtain after putting the prefactor the desired expression (see Fig. 4.2). □

4.1.3 Lamb shift

Quantum electrodynamics (QED) is outside the scope of this introductory text but a flavor of its origin can be obtained from Welton's picture for the Lamb shift. Welton argued that the zero-point fluctuations of the quantized electromagnetic field will give rise to quiver motion of the electrons relative to the nucleus. This quiver motion will reduce the Coulomb interaction of the electrons with the nucleus because, like the Zitterbewegung in the case of the Darwin correction, the zero-point motion will tend to delocalize the electron. Thus, also in the present case we shall represent the electron by a centrally symmetric charge distribution $\varrho(r')$ normalized to the total charge, $\int \varrho(r')d\mathbf{r}' = -e$. Therefore, we simply presume the charge to be homogeneously distributed over a sphere of radius R_L. Hence, the Lamb shift can be estimated in the same way as the Darwin shift, which leads to the result

$$\Delta E^{\mathrm{Lamb}} = \frac{Ze^2}{4\pi\varepsilon_0}\frac{R_L^2}{10}R_{nl}^2(0). \tag{4.26}$$

This means that the Lamb shift only affects the s states. Without further explanation we state that the radius can be estimated to be $R_L \simeq \sqrt{3\alpha}\lambda_C$, which means that the Lamb shift is a few percent of the Darwin shift.

4.2 Hamiltonian for electronic motion in magnetic fields

In the presence of an externally applied magnetic field $\mathbf{B}$ the motion of a charged particle is affected by the *Lorentz* force, $\mathbf{F} = q(\mathbf{v}\times\mathbf{B})$, with q the charge of the particle and $\mathbf{v} = \dot{\mathbf{r}}$ its velocity. Unlike the electrical force $\mathbf{F} = q\mathbf{E}$, the Lorentz force is a *velocity dependent force.* It is an example of a *generalized force* for which a *generalized potential function* may be defined such that the canonical description of classical mechanics remains valid (see Problem 4.2). The generalized potential function for a particle of charge q is given by

$$U(\mathbf{r},\mathbf{v},t) = q(\varphi - \mathbf{v}\cdot\mathbf{A}). \tag{4.27}$$

Here $\varphi(\mathbf{r},t)$ is the scalar potential and $\mathbf{A}(\mathbf{r},t)$ the vector potential of the electromagnetic field, with $\mathbf{B} = \boldsymbol{\nabla}\times\mathbf{A}$ and $\mathbf{E} = -\boldsymbol{\nabla}\varphi - \partial\mathbf{A}/\partial t$ expressions for the magnetic and electric fields, respectively.[1]

Like the force, also the momentum of charged particles is affected by the $\mathbf{B}$ field. The *generalized momentum* is given by the canonical expression $p_j = \partial\mathcal{L}/\partial v_j$, where $\mathcal{L} = T - U$ is the Lagrangian, with T the kinetic energy and U the generalized potential function of a system. Substituting $T = \frac{1}{2}m\mathbf{v}^2$ for the kinetic energy and Eq. (4.27) for the generalized potential energy we obtain for the canonical momentum

$$\mathbf{p} = m\mathbf{v} + q\mathbf{A}, \tag{4.28}$$

which shows that a particle of mass m and charge q does not carry only *kinetic momentum* $m\mathbf{v}$ but also *electromagnetic momentum* $q\mathbf{A}$.

To calculate the energy eigenstates of the atom in the presence of magnetic fields we have to quantize the classical Hamiltonian

$$H = \mathbf{p}\cdot\mathbf{v} - \mathcal{L}. \tag{4.29}$$

Substituting the Lagrangian we obtain

$$H = m\mathbf{v}^2 + q\mathbf{A}\cdot\mathbf{v} - \frac{1}{2}m\mathbf{v}^2 + q(\varphi - \mathbf{v}\cdot\mathbf{A}) = \frac{1}{2}m\mathbf{v}^2 + q\,\varphi(r), \tag{4.30}$$

which is seen to coincide with the familiar expression (1.1). To prepare for quantization we rewrite the classical Hamiltonian in terms of the canonical momentum

$$H = \frac{1}{2m}(\mathbf{p} - q\mathbf{A})^2 + q\,\varphi(r). \tag{4.31}$$

---

[1] Note that the expressions for the fields indeed satisfy the Maxwell equations $\boldsymbol{\nabla}\cdot\mathbf{B} = 0$ and $\nabla\times\mathbf{E} = -\partial\mathbf{B}/\partial t$ because $\nabla\cdot(\nabla\times\mathbf{A}) = 0$ for any vector $\mathbf{A}$ and $\nabla\times\boldsymbol{\nabla}\varphi = 0$ for any scalar φ.

With the identification $\mathbf{p} \to -i\hbar\boldsymbol{\nabla}$ we obtain the quantum mechanical Hamiltonian for a charged particle in a classical electromagnetic field

$$\mathcal{H} = \frac{1}{2m}(-i\hbar\boldsymbol{\nabla} - q\mathbf{A})^2 + q\,\varphi(r). \tag{4.32}$$

To obtain the well-known Zeeman Hamiltonian we write Eq. (4.32) in the form[1]

$$\mathcal{H} = -\frac{\hbar^2}{2m}\Delta + \frac{i\hbar q}{2m}[(\boldsymbol{\nabla}\cdot\mathbf{A}) + (\mathbf{A}\cdot\boldsymbol{\nabla})] + \frac{q^2}{2m}\mathbf{A}^2 + q\,\varphi(r). \tag{4.33}$$

This expression may be simplified using the *gauge freedom*: $\mathbf{A}$ is not uniquely defined. Because we have $\boldsymbol{\nabla}\times\boldsymbol{\nabla}\chi = 0$ for any choice of scalar potential χ, any vector potential $\mathbf{A} = \mathbf{A}'+\boldsymbol{\nabla}\chi$ results with $\mathbf{B} = \boldsymbol{\nabla}\times\mathbf{A}$ in the same magnetic field. Hence, by choosing $\Delta\chi = -\boldsymbol{\nabla}\cdot\mathbf{A}'$ the vector potential can be made divergence-free

$$\boldsymbol{\nabla}\cdot\mathbf{A} = 0. \tag{4.34}$$

This choice for the vector potential is called the *Coulomb gauge*, also known under the name *radiation gauge*. It is the preferred gauge for atomic physics [27]. In the Coulomb gauge, the Hamiltonian (4.33) takes the form

$$\mathcal{H} = -\frac{\hbar^2}{2m}\Delta + \mathcal{V}(r) + \frac{i\hbar q}{m}\mathbf{A}\cdot\boldsymbol{\nabla} + \frac{q^2}{2m}\mathbf{A}^2, \tag{4.35}$$

where $\mathcal{V}(r) = q\,\varphi(r)$ is the Coulomb energy of the charge q.

Specializing further to a *homogeneous* magnetic field the vector potential can be written as[2]

$$\mathbf{A} = \tfrac{1}{2}\mathbf{B}\times\mathbf{r}. \tag{4.36}$$

This relation is readily verified by direct substitution in $\mathbf{B} = \boldsymbol{\nabla}\times\mathbf{A}$. Substituting Eq. (4.36) into Eq. (4.35) we obtain[3]

$$\mathcal{H} = \mathcal{H}_0 - \frac{q}{2m}\mathbf{L}\cdot\mathbf{B} + \frac{q^2}{8m}r_\perp^2\mathbf{B}^2, \tag{4.37}$$

where $\mathcal{H}_0$ is the Schrödinger Hamiltonian, the second term stands for the orbital Zeeman coupling (cf. Section 4.3.3) and the third term for the atomic diamagnetism (cf. Section 4.3.2). The operator $r_\perp = r\sin\theta$ represents the component of the radius vector perpendicular to the direction of $\mathbf{B}$.

Problem 4.2. Show that the force $\mathbf{F} = q(\mathbf{E} + \mathbf{v}\times\mathbf{B})$ acting on a charge q, moving at velocity $\mathbf{v}$ in an electromagnetic field given by $\mathbf{E}(t)$ and $\mathbf{B}(t)$, may be described as arising from a generalized potential function $U(\mathbf{r},\mathbf{v},t) = q\,(\varphi - \mathbf{v}\cdot\mathbf{A})$, where $\varphi(\mathbf{r})$ is the scalar potential (Coulomb potential) and $\mathbf{A}(\mathbf{r},t)$ the vector potential of the electromagnetic field.

Solution. In order to satisfy the laws of classical mechanics a system should satisfy the Lagrange equations,

$$\frac{d}{dt}\frac{\partial\mathcal{L}}{\partial\dot{q}_i} - \frac{\partial\mathcal{L}}{\partial q_i} = 0, \tag{4.38}$$

where $\mathcal{L}(q_i,\dot{q}_i,t) \equiv T(q_i,\dot{q}_i,t) - U(q_i,\dot{q}_i,t)$ is the Lagrangian and $\{q_i,\dot{q}_i,t\}$ the generalized coordinates, with $i \in \{1,2,\cdots,l\}$ the coordinate index and l the number of degrees of freedom of the system. Substituting the Lagrangian into Eq. (4.38) the Lagrange equations take the form

$$\frac{d}{dt}\frac{\partial T}{\partial\dot{q}_i} - \frac{\partial T}{\partial q_i} = -\frac{\partial U}{\partial q_i} + \frac{d}{dt}\left(\frac{\partial U}{\partial\dot{q}_i}\right) \equiv Q_i(q_i,\dot{q}_i,t). \tag{4.39}$$

---

[1] Note that, *in general*, ∇ and $\mathbf{A}$ do *not* commute, $(\nabla\cdot\mathbf{A})\,\phi = \phi\,(\nabla\cdot\mathbf{A}) + (\mathbf{A}\cdot\nabla)\,\phi$.

[2] Note that $\nabla\cdot\mathbf{r} = 3$ and $(\mathbf{B}\cdot\nabla)\mathbf{r} = \mathbf{B}$.

[3] With Eq.(1.22) we obtain $2i\hbar\mathbf{A}\cdot\nabla = i\hbar(\mathbf{B}\times\mathbf{r})\cdot\nabla = \mathbf{B}\cdot(\mathbf{r}\times i\hbar\nabla) = -\mathbf{B}\cdot\mathbf{L}$.
Note that $(\mathbf{r}\times\mathbf{B})^2 = r^2\sin^2\theta\,B^2 = r_\perp^2\,\mathbf{B}\cdot\mathbf{B}$.

To solve our problem we turn to the case of a single body of mass m. In cartesian coordinates, the kinetic energy of the body is given by $T = \frac{1}{2}m\dot{r}_i^2$ where r_i represents its position, with $i \in \{x, y, z\}$, and $\dot{r}_i$ its velocity. Evaluating the l.h.s. of Eq. (4.39) the Lagrange equations for the motion become $m\ddot{r}_i = Q_i(r_i, \dot{r}_i, t)$, which is just the Newton equation of motion if Q_i is interpreted as a generalized force. Thus our task is reduced to demonstrating that the Lorentz force is obtained by evaluating the generalized force

$$Q_i(r_i, v_i, t) = -\frac{\partial U}{\partial r_i} + \frac{d}{dt}\left(\frac{\partial U}{\partial v_i}\right), \tag{4.40}$$

starting from the generalized potential function $U(\mathbf{r}, \mathbf{v}, t) = q\,(\varphi - \mathbf{v}\cdot\mathbf{A})$, which with the summation convention takes the form $U = q\,[\varphi\,(\mathbf{r}) - v_j A_j\,(\mathbf{r}, t)]$. The first term of Eq. (4.40) yields

$$-\,\partial_i U = q\,[-\partial_i\varphi + v_j\partial_i A_j\,(\mathbf{r}, t)]\,. \tag{4.41}$$

and the second term can be written as

$$\begin{aligned}\frac{d}{dt}\left(\frac{\partial U}{\partial v_i}\right) &= q\frac{d}{dt}\left(\frac{\partial\varphi\,(\mathbf{r},t)}{\partial v_i} - \frac{\partial v_j A_j\,(\mathbf{r},t)}{\partial v_i}\right) = -q\frac{d}{dt}A_i\,(\mathbf{r},t)\\ &= -q\left(\frac{\partial A_i\,(\mathbf{r},t)}{\partial t} + \frac{\partial A_i\,(\mathbf{r},t)}{\partial r_j}\frac{dr_j}{dt}\right) = q\,[-\partial_t A_i\,(\mathbf{r},t) - \dot{r}_j\partial_j A_i\,(\mathbf{r},t)]\,. \end{aligned}\tag{4.42}$$

Combining Eqs. (4.41) and (4.42) we obtain for the generalized force

$$Q_i = q\,[-\partial_i\varphi - \partial_t A_i + v_j\partial_i A_j - v_j\partial_j A_i]\,. \tag{4.43}$$

Recalling the expression for the $\mathbf{E}$ field in terms of the scalar and vector potentials, $\mathbf{E} = -\boldsymbol{\nabla}\varphi - \partial\mathbf{A}/\partial t$, we recognize in the first two terms within the brackets of Eq. (4.43) the E_i-component of the $\mathbf{E}$ field,

$$E_i = -\partial_i\varphi - \partial_t A_i. \tag{4.44}$$

Likewise, using $\mathbf{B} = \boldsymbol{\nabla}\times\mathbf{A}$, we recognize in the last two terms the component $(\mathbf{v}\times\mathbf{B})_i$ of the $\mathbf{v}\times\mathbf{B}$ field,

$$(\mathbf{v}\times\mathbf{B})_i = \varepsilon_{ijk}v_j(\boldsymbol{\nabla}\times\mathbf{A})_k = \varepsilon_{ijk}\varepsilon_{klm}v_j\partial_l A_m = v_j\partial_i A_j - v_j\partial_j A_i. \tag{4.45}$$

Hence, Eq. (4.43) can be rewritten as $Q_i = q\left[E_i + (\mathbf{v}\times\mathbf{B})_i\right]$, which is indeed the expression for the Lorentz force as had to be proved. □

4.3 Hydrogen-like atom in an external magnetic field

4.3.1 Effective magnetic moment

Let us consider a hydrogen-like atom at position $\mathbf{r}$ passing through an *inhomogeneous* magnetic field $\mathbf{B}(\mathbf{r})$ as is sketched for a cloud of atoms in Fig. 4.3. Suppose that the atom is in eigenstate $|nlm\rangle$ with respect to the quantization axis defined by the direction of $\mathbf{B}$. If this direction does not change along the trajectory of the atom (or changes adiabatically; i.e., sufficiently slowly), the atom stays in the same eigenstate and its energy can be regarded as a state-dependent effective potential,

$$\mathcal{U}(\mathbf{r}) = \langle\mathcal{H}_0\rangle_{nlm} + \frac{e}{2m_r}\langle\mathbf{L}\cdot\mathbf{B}(\mathbf{r})\rangle_{nlm} + \frac{e^2}{8m_r}\langle r_\perp^2\rangle_{nlm}\mathbf{B}^2(\mathbf{r}). \tag{4.46}$$

To obtain this expression we substituted the charge $q = -e$ and the reduced mass m_r of the electron into the Hamiltonian (4.37). The use of ordinary first-order perturbation theory in this context is justified in Section 4.3.3. The presence of the field gradient results in a force on the atom,

$$\mathbf{F} = -\,\mathrm{grad}\,\mathcal{U}(\mathbf{r}) = -\frac{\partial\mathcal{U}}{\partial B}\,\mathrm{grad}\,B = \mu_{\text{eff}}\,\mathrm{grad}\,B. \tag{4.47}$$

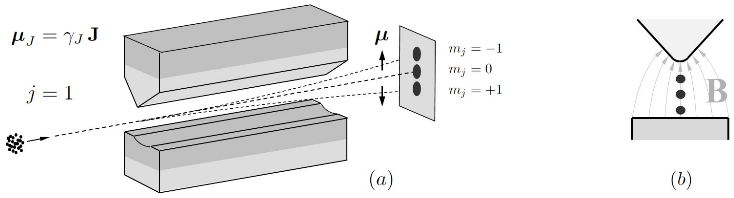

Figure 4.3: Stern-Gerlach apparatus for determining the magnetic moment of atoms by measuring the magnetic force induced by the gradient of $|\mathbf{B}(\mathbf{r})|$: (a) for atoms with unit total electronic angular momentum $J = 1$ three spots are observed. Note that $\gamma_J < 0$; i.e., atoms with magnetic moment polarized parallel to the magnetic field are deflected towards high field (*high-field seekers*); those with magnetic moment anti-parallel towards low field (*low-field seekers*); in state $m_J = 0$ the atoms are not deflected; (b) magnet configuration with a constant magnetic field gradient along the vertical direction in the symmetry plane.

Hence, the force depends on the gradient of the *absolute value* $B(\mathbf{r}) = |\mathbf{B}(\mathbf{r})|$ and can be used to measure μ_{eff}, the *effective magnetic moment.* This method is called the *Stern-Gerlach method* [105]. The effective magnetic moment is given by the first derivative of the effective potential

$$\mu_{\text{eff}} = -\frac{\partial \mathcal{U}}{\partial B} = -(e\hbar/2m_r)m_l - \left(e^2/4m_r\right)\langle r_\perp^2\rangle B. \tag{4.48}$$

The second derivative

$$\alpha_M = \frac{\partial^2 \mathcal{U}}{\partial B^2} = \left(e^2/4m_r\right)\langle r_\perp^2\rangle \tag{4.49}$$

is known as the *magnetic polarizability (magnetizability).* To obtain these results we approximated the field as homogeneous over the size of the atom.

Eqs. (4.46) and (4.48) suggests to rewrite the Hamiltonian (4.37) in the form of an effective Hamiltonian for a classical magnetic dipole in a magnetic field,

$$\mathcal{H} = \mathcal{H}_0 - \boldsymbol{\mu}_L \cdot \mathbf{B} - \tfrac{1}{2}\boldsymbol{\mu}_{dia} \cdot \mathbf{B}, \tag{4.50}$$

where

$$\boldsymbol{\mu}_L = -(e/2m_r)\mathbf{L} \tag{4.51}$$

represents the operator of a *permanent* magnetic moment and is called the *orbital magnetic moment*, and

$$\boldsymbol{\mu}_{dia} = -\left(e^2/4m_r\right) r^2 \sin^2\theta\, \mathbf{B} \equiv -\alpha_M \mathbf{B}, \tag{4.52}$$

is the operator for an *induced* magnetic moment known as the *diamagnetic moment.* As expected for an induced moment, $\boldsymbol{\mu}_{dia}$ opposes the direction of the applied magnetic field $\mathbf{B}$; also $\boldsymbol{\mu}_L$ and $\mathbf{L}$ point in opposite directions, in this case caused by the negative electron charge.

The relation between the magnetic moment $\boldsymbol{\mu}_L$ and the angular momentum $\mathbf{L}$ will be written in the form [1]

$$\boldsymbol{\mu}_L = \gamma_L \mathbf{L} \equiv -g_L \mu_B \left(\mathbf{L}/\hbar\right), \tag{4.53}$$

where $\mathbf{L}/\hbar$ is the dimensionless angular momentum operator ($\mathbf{L}$ in units of $\hbar$). The coefficient

$$\gamma_L = -e/2m_r \equiv -g_L \mu_B/\hbar, \tag{4.54}$$

relating the magnetic moment $\boldsymbol{\mu}_L$ to the angular momentum $\mathbf{L}$ in Eq. (4.51), is called the *gyromagnetic ratio* of the orbiting electron. Its value coincides with that of an orbiting classical body of charge $-e$ and mass m_r. The quantity

$$\mu_B = e\hbar/2m_e \tag{4.55}$$

---

[1] In these lectures we define gyromagnetic ratios always in the same way: positive if the magnetic moment is parallel to the angular momentum. The electron g factors (g_L and g_e) are (traditionally) defined as positive numbers. In contrast, the nuclear g factors will be defined to have the same sign as the nuclear gyromagnetic ratio.

is the *Bohr magneton* ($\mu_B \simeq 9.27 \times 10^{-24}$ J/T). The prefactor g_L is called the orbital g factor. Note that g_L is defined as a positive dimensionless number. Specification of the g factor is the conventional way to compare small differences in orbital magnetic moment between the elements. The orbital g factor can be expressed in terms of the electron-to-nucleus mass ratio

$$g_L = m_e/m_r = (1 + m_e/M) \simeq 1. \tag{4.56}$$

4.3.2 Diamagnetic coupling

Atomic *diamagnetism* finds its origin in the third term of the Hamiltonian (4.50),

$$\mathcal{H}_{dia} = -\tfrac{1}{2}\boldsymbol{\mu}_{dia} \cdot \mathbf{B} = \tfrac{1}{2}\alpha_M B^2. \tag{4.57}$$

For hydrogenic atoms in s states, $|nlm_l\rangle = |n00\rangle \equiv |ns\rangle$, which are eigenstates of the Schrödinger Hamiltonian $\mathcal{H}_0$, the magnetic polarizability can be calculated with the expression for ordinary first-order perturbation theory

$$\alpha_M^{(ns)} = \langle ns|\alpha_M|ns\rangle = (e^2/4m_r)\langle 00|\sin^2\theta|00\rangle\langle r^2\rangle_{ns}. \tag{4.58}$$

The angular average evaluates to $\langle 00|\sin^2\theta|00\rangle = 2/3$ (see Problem 2.5); the reduced matrix element for the radial average follows with Eq. (2.49). For $l = 0$ we obtain

$$\alpha_M^{(1s)} = \frac{n^2}{Z^2}\frac{e^2a^2}{12m_r}(5n^2 + 1). \tag{4.59}$$

Note that the diamagnetism of the hydrogen ground state is *extremely small*; for a $1\,T$ applied field the induced moment is only $\mu_{dia} = (ea^2/\hbar)g_l\mu_B B \simeq 4 \times 10^{-6}\mu_B$. However, it is important for high-n Rydberg atoms ($n \gtrsim 50$) because the polarizability scales with n^4.

For materials, the magnetic polarizability is related to the *diamagnetic susceptibility* χ_m^{dia}, which is a dimensionless number determining the *diamagnetic magnetization* (magnetic moment per unit volume) for a given applied field, $\mathbf{M}_{dia} = \chi_m^{dia}\mathbf{H}$. For dilute systems (in which the mutual interaction between the atoms may be neglected) the magnetization at position $\mathbf{r}$ is simply the product of the diamagnetic moment and the atomic (number) density $n(\mathbf{r})$,

$$\mathbf{M}_{dia} = n(\mathbf{r})\boldsymbol{\mu}_{dia}. \tag{4.60}$$

Using Eq. (4.52) and $\mathbf{B} = \mu_0\mathbf{H}$ we find for the diamagnetic susceptibility of dilute systems

$$\chi_m^{dia} = -\mu_0\alpha_M\, n(\mathbf{r}). \tag{4.61}$$

4.3.3 Orbital Zeeman coupling

The *orbital Zeeman effect* finds its origin in the second term of the effective Hamiltonian (4.50) which is known as the orbital Zeeman Hamiltonian

$$\mathcal{H}_Z = -\boldsymbol{\mu}_L \cdot \mathbf{B}, \tag{4.62}$$

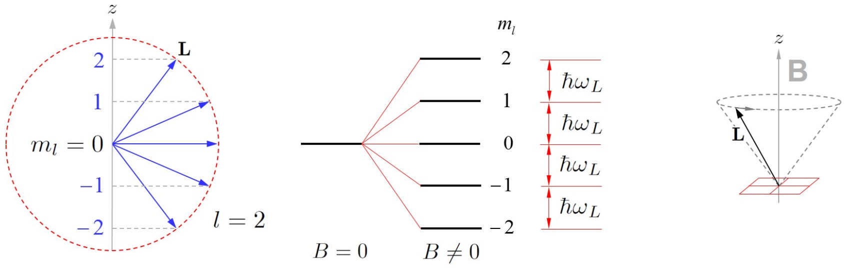
where $\boldsymbol{\mu}_L$ is the orbital magnetic moment operator (4.53). Note that Eq. (4.62) coincides with the expression for the energy of a classical magnetic dipole moment in a magnetic field.

Let us analyze how the degeneracy of the magnetic sublevels is lifted by applying a magnetic field.[1] Since $\mathbf{L}^2$ and L_z commute with $\mathcal{H}_0$ the orbital Zeeman Hamiltonian is *diagonal* in the hydrogenic basis, $\{|nlm_l\rangle\}$; i.e., the orbital Zeeman shift is given by

$$\Delta E_Z = \langle nlm_l|\mathcal{H}_Z|nlm_l\rangle = \langle lm_l|\mathcal{H}_Z|lm_l\rangle. \tag{4.63}$$

---

[1] Pure orbital Zeeman splitting is not observed in atomic systems. It always comes in combination with spin-orbit interaction (see Section 4.5.1).



(a) (b) (c)

Figure 4.4: (a) Semi-classical vector model of angular momentum for the case $l = 2$. The diagram shows the $2l+1$ projections of the semi-classical vector $\mathbf{L}$ along the direction of the magnetic field (z-direction); (b) The $(2l+1)$-fold degeneracy of the energy-levels is lifted when applying a magnetic field (Zeeman effect-in the absence of electronic spin). For 1 Bohr magneton the splitting amounts 1.4 MHz/Gauss (67 μK/Gauss); (c) The projections stay constant in time, also in the presence of Larmor precession which has the same angular frequency (ω_L) for all m_l values.

Hence, l and m_l are good quantum numbers and, for given l, the Zeeman operator acts in a $(2l+1)$-dimensional sector of Hilbert space. The relativistic corrections do not affect the magnetic shifts and diamagnetic corrections may be neglected as long as the magnetic field is sufficiently small.

Substituting Eq. (4.53) into (4.62) the Zeeman Hamiltonian becomes

$$\mathcal{H}_Z = -\gamma_L \mathbf{L} \cdot \mathbf{B} = g_L \mu_B B \left(L_z / \hbar \right), \tag{4.64}$$

where the z direction is again chosen along the direction of the $\mathbf{B}$ field. This Hamiltonian expresses the coupling of $\mathbf{L}$ to the $\mathbf{B}$ field (*orbital Zeeman coupling*). In this notation the Zeeman shifts of the $2l+1$ magnetic sublevels are given by

$$\Delta E_Z = -\gamma_L B \langle l m_l | L_z | l m_l \rangle = g_L \mu_B B m_l. \tag{4.65}$$

Comparing Eqs. (4.67) and (4.65) we note that, classically spoken, $\boldsymbol{\mu}_L$ is never parallel to $\mathbf{B}$ (see Fig. 4.4a). The quantity referred to as the *magnitude* of the orbital magnetic moment (short: *the* orbital moment) is defined as

$$\mu_L \equiv g_L (e/2m_e) \langle ll | L_z | ll \rangle = g_L \mu_B l. \tag{4.66}$$

It corresponds to the *maximum observable* magnetic moment (for given l) and should not be confused with the operator $\boldsymbol{\mu}_L$ or with the *semi-classical magnitude* of the orbital moment,

$$\sqrt{\langle \boldsymbol{\mu}_L^2 \rangle} = \sqrt{\langle l m_l | \boldsymbol{\mu}_L \cdot \boldsymbol{\mu}_L | l m_l \rangle} = g_L (e/2m_e) \sqrt{\langle l m_l | \mathbf{L}^2 | l m_l \rangle} = g_L \mu_B \sqrt{l(l+1)}. \tag{4.67}$$

As mentioned in Section 4.3.1 the *effective magnetic moment* of a given magnetic sublevel is defined as the derivative of the Zeeman energy with respect to magnetic field. With Eq. (4.65) we find

$$\mu_{\text{eff}} = -\partial [\Delta E_Z(B)] / \partial B = -g_L \mu_B m_l. \tag{4.68}$$

For the purely orbital Zeeman coupling μ_{eff} is a constant for given value of m_l but in more general cases of magnetic coupling it will depend on magnetic field (cf. Section 4.7). For an effective magnetic moment of 1 Bohr magneton, $\mu_{\text{eff}} = \mu_B \simeq 9.27 \times 10^{-24}$ J/T, the level shift corresponds to 1.4 MHz/Gauss (67 μK/Gauss). With Eq. (4.65) we have established that in a magnetic field the $(2l+1)$-fold orbital degeneracy is lifted, with the lowest energy corresponding to the lowest value of the magnetic quantum number ($m_l = -l$). This is illustrated in Fig. 4.4b.

4.3.4 Larmor precession

In a semi-classical picture, the Zeeman Hamiltonian (4.62) gives rise to a torque,

$$d\mathbf{L}(t)/dt = \boldsymbol{\mu}_L \times \mathbf{B}, \tag{4.69}$$

tending to line up the magnetic moment with the magnetic field giving rise to precession about $\mathbf{B}$ because hamiltonian evolution is dissipation free. This is known as *Larmor precession.* Substituting Eq. (4.51) into Eq. (4.69) the expression for the torque describes the precession of the angular momentum vector $\mathbf{L}$ about the field direction,

$$d\mathbf{L}(t)/dt = \gamma_L \mathbf{L} \times \mathbf{B}. \tag{4.70}$$

Rewriting this expression in the form

$$d\mathbf{L}/dt = \boldsymbol{\omega}_L \times \mathbf{L} \tag{4.71}$$

we find that the angular momentum $\mathbf{L}$ precesses about $\mathbf{B}$ at angular frequency

$$\boldsymbol{\omega}_L = \gamma_L \mathbf{B}. \tag{4.72}$$

This is illustrated in Fig. 4.4*c.* The precession frequency is known as the *Larmor* frequency,

$$\omega_L \equiv |\boldsymbol{\omega}_L| = g_L \mu_B B/\hbar. \tag{4.73}$$

In terms of the Larmor frequency the Zeeman energy can be written as

$$\Delta E_Z = -\hbar\gamma_L B m_l = g_L \mu_B B m_l = \hbar\omega_L m_l. \tag{4.74}$$

Quantum mechanically, the precession follows from the Heisenberg equations of motion. In this approach all time-dependence is contained in the Heisenberg operator $\mathbf{L}(t) \equiv U^\dagger(t,t_0)\mathbf{L}U(t,t_0)$, where $U(t,t_0) = \exp[-i(t-t_0)\mathcal{H}_Z/\hbar]$ is the evolution operator (see Appendix F.2). As the Zeeman Hamiltonian is time independent, the precession of $\mathbf{L}(t)$ is described by

$$d\mathbf{L}(t)/dt = -\,(i/\hbar)\,[\mathbf{L}(t), \mathcal{H}_Z]. \tag{4.75}$$

Writing the Zeeman Hamiltonian in the form $\mathcal{H}_Z = -\gamma_L\, \mathbf{L}\cdot\mathbf{B}$ the equation of motion becomes

$$d\mathbf{L}(t)/dt = (i/\hbar)\,\gamma_L[\mathbf{L}(t), \mathbf{L}(t)\cdot\mathbf{B}]. \tag{4.76}$$

To evaluate this expression we consider the time evolution of the angular momentum components $L_i(t)$. With the aid of the commutation relations (1.29) and using the Einstein summation convention we have $[L_i, L_k] = -\varepsilon_{ijk} i\hbar L_j$ and Eq. (4.76) becomes

$$dL_i/dt = (i/\hbar)\,\gamma_L[L_i, L_k B_k] = (i/\hbar)\,\gamma_L[L_i, L_k]B_k = \gamma_L \varepsilon_{ijk} L_j B_k. \tag{4.77}$$

Returning to the vector notation this becomes

$$d\mathbf{L}(t)/dt = \gamma_L\left[\mathbf{L}(t)\times\mathbf{B}\right]. \tag{4.78}$$

This expression may be rewritten in two equivalent forms

$$d\mathbf{L}/dt = \boldsymbol{\mu}_L \times \mathbf{B} \text{ and } \quad d\mathbf{L}/dt = \boldsymbol{\omega}_L \times \mathbf{L}. \tag{4.79}$$

Here the *operator* $\mathbf{L}$ is found to be described by the well-known equation of motion (4.71) from classical mechanics describing the precession (at angular frequency ω_L about the direction $\hat{\mathbf{n}} = \boldsymbol{\omega}_{\mathbf{L}}/|\boldsymbol{\omega}_L|$) of a spinning top of angular momentum $\mathbf{L}$ under the influence of the torque $\boldsymbol{\mu}_L \times \mathbf{B}$.

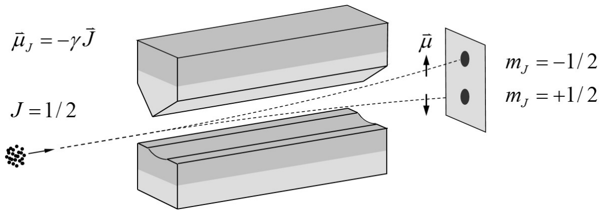


Figure 4.5: Observation of half-integral angular momentum atoms by the Stern-Gerlach method.

4.3.5 Spin

Spin was postulated by Goudsmit and Uhlenbeck in 1925 to provide a *physical interpretation* for the appearance of half-integral quantum numbers in the analysis of the atomic spectra [113, 114]. At the time of the proposal spectroscopic evidence for the existence of half integral quantum numbers was available and particularly elegantly demonstrated in the atomic beam experiment of Stern and Gerlach with silver atoms - see Fig. 4.5 [50]. Building on the spectroscopic evidence Pauli had already established the double-valuedness of the *electronic* wavefunction (see Appendix F.1.4) which points to the presence of an additional quantum number for the electron (a fourth degree of freedom) but he refrained from giving an interpretation. In his words the double-valuedness was "not describable classically" [80]. In their postulate Uhlenbeck and Goudsmit attribute this degree of freedom to self-rotation of the electron with angular momentum 1/2 in units of $\hbar$ and a *gyromagnetic ratio* twice as large as the orbital value $-e/2m_e$.

Superficially, the presence of electron spin may not come as a surprise because it is well known from classical mechanics that an orbiting satellite will generally show solid body rotation. However, in 1925 the modeling of the electron as some rotating cloud of charge had a two decade history of disappointment. It was not clear what was holding the charge together and to generate the required magnetic moment special relativity had to be violated; i.e., the cloud had to rotate so fast that locally the speed of light was exceeded. A difficulty of all mechanical models was that they even failed to provide a *self-consistent* description for the *gyromagnetic ratio.* The postulate of Goudsmit and Uhlenbeck was no exception in this respect: on the one hand the g factor of the electron had to have the value 2 (to describe the Zeeman effect in high fields - see Section 4.7.4); on the other hand using this value to estimate the zero-field splitting the calculated value was a factor of 2 too large (by itself this would imply a g factor of 4). Therefore, it is not surprising that the postulate only started to gain acceptance after it was demonstrated by Thomas that the proper relativistic analysis yields the value 2 in both cases (see Section 4.4.2) [108, 110]. However, it remained to be explained why spin represents a *fixed* quantity of angular momentum (called the *intrinsic angular momentum*) rather than variable amounts as observed for classical bodies.

In 1928 the mentioned properties were captured in the famous Dirac theory for the electron [33]. In this theory the spinning electron emerges as a manifestly non-classical object. It represents the first example of an *elementary particle* on which the *standard model* is based. In this respect the postulate marks the beginning of *particle physics.* The electron is an elementary particle of mass m_e, elementary charge $q = -e$ and spin $s = \frac{1}{2}$. Within experimental error the particle is of *zero size* [46] and *without* electric dipole moment [59]. The particle spin, together with its magnetic quantum number $m_s = \pm\frac{1}{2}$ defines the spin state of the electron. A difficulty of the Dirac theory is that the energy contained in the electric field of a point charge diverges. It took until 1948 before this problem was resolved with the development of *quantum electrodynamics* (QED) by Tomonaga, Schwinger and Feynman. Close to the singularity the electromagnetic energy density becomes so large that *virtual* excitation (see Appendix H.2) of electron-positron pairs becomes substantial. These virtual pairs constitute electric dipoles that live only briefly but long enough to be polarized by the electric field. This is known as *vacuum polarization.* The induced electric field counteracts the Coulomb field of the electron in such a way that the divergence can be eliminated and the experimental values of the electron charge and mass are obtained.

In view of the above it is evident that we should not think simplistically about the electron. This being said, the essential atomic physics can be explained without entering in the origin of spin and so we shall do; after all, the spin was postulated to successfully represent the properties of the atom. An exceptionally lucent account of the early developments that led to our current notion of spin is given in the book *The Story of Spin* by Tomonaga [112].

4.3.6 Spin Zeeman coupling

The spin manifests itself by its magnetic moment

$$\boldsymbol{\mu}_s = \gamma_e \mathbf{S} \equiv -g_e \mu_B \left(\mathbf{S}/\hbar\right), \tag{4.80}$$

where $\mathbf{S}$ is the electron-spin operator and

$$\gamma_e \equiv -g_e \mu_B/\hbar \tag{4.81}$$

the electron gyromagnetic ratio, $\gamma_e/2\pi \simeq -2.8025$ MHz/Gauss, with μ_B the Bohr magneton and g_e the electron g factor defined as a *positive* number. Hence, like $\boldsymbol{\mu}_L$ and $\mathbf{L}$ also $\boldsymbol{\mu}_s$ and $\mathbf{S}$ point in opposite directions. In analogy to the orbital case (4.66) the *magnitude* of the intrinsic magnetic moment (short: *the* intrinsic moment) is defined as the maximum observable moment,

$$\mu_e \equiv \tfrac{1}{2} g_e \mu_B. \tag{4.82}$$

Advanced analysis based on the Dirac theory for the electron predicts $g_e = 2$. Experiment shows g_e to be slightly larger, $g_e \simeq 2.002\,319$. Therefore, the electron is said to have an *anomalous magnetic moment* [67],

$$g_e = 2(1 + a_e). \tag{4.83}$$

The deviation is known as the *electron anomaly*, $a_e \equiv (g_e - 2)/2 \simeq \alpha/2\pi$, with numerical value $a_e \simeq 1.159\,65 \times 10^{-3}$ [77]. The electron anomaly finds its origin in the zero-point fluctuations of the electromagnetic field. The free-electron value differs slightly from that of electrons bound in atoms. It continues to be subject of intensive experimental and theoretical research as it provides an important test of quantum electrodynamics (QED). In contemporary experiments the spin state of a single electron is measured without destroying the state by observing spin-flip events of a trapped electron in real time [77, 46, 54]. This is an example of a Quantum Non Demolition (QND) experiment. It has demolished old wisdom [82] that it is fundamentally impossible to observe the magnetic moment of an electron by a Stern-Gerlach-like experiment [30].

Knowing the magnetic moment, the spin Zeeman Hamiltonian takes the generic form

$$\mathcal{H}_Z = -\boldsymbol{\mu}_s \cdot \mathbf{B}. \tag{4.84}$$

Substituting Eq. (4.80) we obtain

$$\mathcal{H}_Z = (g_e \mu_B/\hbar)\, \mathbf{S} \cdot \mathbf{B} = g_e \mu_B B \left(S_z/\hbar\right), \tag{4.85}$$

where the z direction is again chosen along the direction of the $\mathbf{B}$ field. This Hamiltonian expresses the coupling of $\mathbf{S}$ to the $\mathbf{B}$ field (*spin Zeeman coupling*). The Zeeman Hamiltonian (4.84) gives rise to a torque, which can be written in two equivalent forms

$$d\mathbf{S}/dt = \boldsymbol{\mu}_s \times \mathbf{B} \text{ and } \quad d\mathbf{S}/dt = \boldsymbol{\omega}_e \times \mathbf{S}, \tag{4.86}$$

where $\boldsymbol{\omega}_e = \gamma_e \mathbf{B}$ is the angular frequency vector. The torque tends to line up the magnetic moment with the magnetic field but (in view of the absence of dissipation) this gives rise to precession about $\mathbf{B}$ at frequency

$$\omega_e = |\boldsymbol{\omega}_e| = g_e \mu_B B/\hbar = (g_e/g_L)\omega_L, \tag{4.87}$$

where ω_L is the Larmor frequency (4.73) and g_L the orbital angular momentum g factor.

We analyze the level splitting by the spin Zeeman coupling in the same way as we did for the orbital Zeeman coupling.[1] Since $\mathbf{S}^2$ and S_z commute with $\mathcal{H}_0$, $\mathbf{L}^2$ and L_z, the spin Zeeman operator is *diagonal* in the hydrogenic basis extended by a spin sector $\{|nlm_l\rangle\} \to \{|nlm_lsm_s\rangle\}$,

$$\Delta E_Z = \langle nlm_lsm_s|\mathcal{H}_Z|nlm_lsm_s\rangle = \langle sm_s|\mathcal{H}_Z|sm_s\rangle. \tag{4.88}$$

Hence, s and m_s are good quantum numbers, with $s = \frac{1}{2}$ for one-electron atoms. In general, the spin Zeeman operator acts in a $(2S+1)$-dimensional sector of Hilbert space. Substituting Eq. (4.85 for $\mathcal{H}_Z$ the spin Zeeman shift becomes

$$\Delta E_Z = -\gamma_e B\langle sm_s|S_z|sm_s\rangle = g_e\mu_B m_s B = (g_e/g_L)m_s\hbar\omega_L. \tag{4.89}$$

Like the orbital Zeeman energy, also the spin Zeeman energy can be expressed in a form containing either the Bohr magneton μ_B or the Larmor frequency ω_L. For a spin-up electron ($g_e \simeq 2$ and $m_s = \frac{1}{2}$) the effective magnetic moment equals 1 Bohr magneton, just like in the case of the orbital Zeeman coupling. Thus, in this case the Zeeman shift is 1.4 MHz/Gauss.[2] To observe the characteristic two spot Stern-Gerlach image of a spin-$\frac{1}{2}$ system (see Fig. 4.5) the effective magnetic moment must be close to 1 Bohr magneton along the semi-classical trajectory of the atoms (in Section 5.4.2 we show that this condition is satisfied for $B > |B_{\mathrm{hfs}}|$, where $|B_{\mathrm{hfs}}|$ is the *hyperfine crossover field*).

4.3.7 Zeeman Hamiltonian for the electron

At this point we can formulate the Zeeman Hamiltonian for the electron, which describes the interaction of the electron with an externally applied static magnetic field. Combining Eqs. (4.84), (4.62) and (4.57) we find,

$$\mathcal{H}_Z = -(\boldsymbol{\mu}_s + \boldsymbol{\mu}_L)\cdot\mathbf{B} + \tfrac{1}{2}\alpha_M B^2. \tag{4.90}$$

Later, in Chapter 5, a nuclear contribution will be added to obtain the Zeeman Hamiltonian for the complete atom. The Zeeman Hamiltonian is an effective hamiltonian. It can be used with perturbation theory as long as the electronic wavefunctions are not substantially distorted by the applied field. This is the case for a large class of experiments in atomic physics laboratories. It breaks down under extreme conditions. Near neutron stars the magnetic field can be millions of times stronger than the strongest fields, 100-1000 T, that can be achieved in laboratories on earth. In these lectures we restrict ourselves to perturbative conditions.

4.4 Fine-structure Hamiltonian

4.4.1 Addition of orbital angular momentum and spin

As long as we may neglect the interaction with the environment the atom represents a closed mechanical system and the total angular momentum is a conserved quantity. In general, this total angular momentum is the result of several contributions. In the description of the atomic fine structure we restrict ourselves to orbital angular momentum ($\mathbf{L}$) and spin ($\mathbf{S}$). The total angular momentum is given by the vector sum

$$\mathbf{J} = \mathbf{L} + \mathbf{S}. \tag{4.91}$$

---

[1] Pure electron spin Zeeman splitting is observed in isotopes of *chromium*, Cr, and *molybdenum*, Mo (see Section 10.3.2). In one-electron atoms spin Zeeman coupling does not occur without hyperfine interaction (see Chapter 5).

[2] Note that we are dealing here with *level* shifts, not to be confused with the Zeeman shift of spin-flip *transition frequencies*, which are twice as big (for spin 1/2).

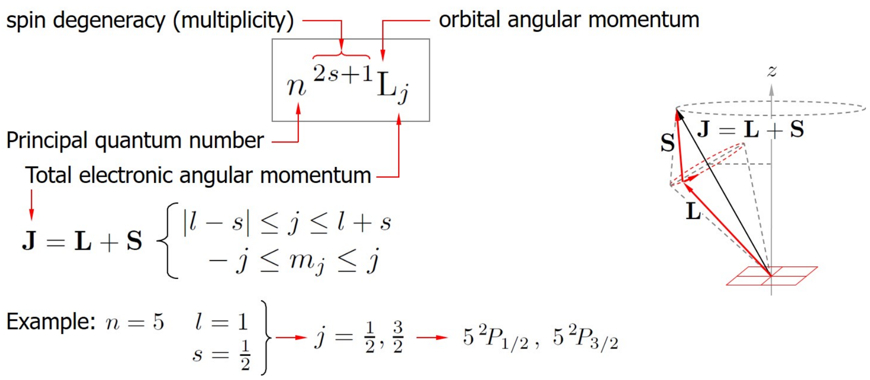

Figure 4.6: Addition of angular momenta allowing for $\mathbf{L}\cdot\mathbf{S}$ coupling. The states (so-called LS Terms), are written in the spectroscopic notation (Term notation) as $n\,^{(2s+1)}\mathrm{L}_j$, where n is the principal quantum number, s the quantum number for the electronic spin, and j the quantum number for the total electronic angular momentum $\mathbf{J}$ (which is a conserved quantity in the absence of coupling to the environment). The symbol L stands for the total orbital angular momentum $\mathrm{L}=S,P,D,F\cdots$ for $l=0,1,2,\cdots$, respectively. Note that the angular momentum projections L_z and S_z are proportional to J_z. This provides the geometric foundation of the Wigner-Eckart theorem as applied to vector operators.

Starting from the commutation relations for $\mathbf{L}$ and $\mathbf{S}$ separately it is straightforward to show that also $\mathbf{J}$ obeys commutation relations of the type (1.29),

$$[J_x,J_y]=i\hbar J_z,\ [J_y,J_z]=i\hbar J_x \text{ and } [J_z,J_x]=i\hbar J_y. \tag{4.92}$$

Recalling Section 3.1 this implies that $\mathbf{J}$ satisfies all properties of quantized angular momenta,

$$\mathbf{J}^2\,|lsj,m_j\rangle=j(j+1)\hbar^2\,|lsj,m_j\rangle \tag{4.93}$$

$$J_z\,|lsj,m_j\rangle=m_j\hbar\,|lsj,m_j\rangle\,, \tag{4.94}$$

with m_j restricted to the interval

$$-j\le m_j\le j. \tag{4.95}$$

In many cases the values of l and s are irrelevant or obvious from the context. In such cases these quantum numbers are usually omitted from the notation, writing simply $|j,m_j\rangle$ rather than $|lsj,m_j\rangle$. As shown in Section 3.10 the value of j is restricted by the values of l and s; j can take all values differing by one unit of angular momentum in the interval as expressed by the *triangle inequality*

$$|l-s|\le j\le l+s. \tag{4.96}$$

Note that j is positive definite for half-integral spin (the vector sum can only become zero if the two angular momenta are equal in magnitude and opposite in sense). The action of the shift operators $J_\pm$ are given by (see Eq. 3.20)

$$J_\pm\,|j,m_j\rangle=\sqrt{j\,(j+1)-m_j(m_j\pm 1)}\hbar\,|j,m_j\pm 1\rangle\,. \tag{4.97}$$

Since the components of $\mathbf{J}$ commute with the Schrödinger Hamiltonian, the total electronic angular momentum is a conserved quantity. Also, when extending the Hamiltonian by a so-called *internal coupling term* of the type $\mathcal{H}'\propto\mathbf{L}\cdot\mathbf{S}$ the total angular momentum $\mathbf{J}$ remains conserved (just as we expect for a closed mechanical system). In the latter case, $\mathbf{L}$ and $\mathbf{S}$ exert a torque on each other, which results (given the absence of dissipation) in a joint precession of $\mathbf{L}$ and $\mathbf{S}$ about $\mathbf{J}$ as is illustrated in Fig. 4.6. This is expressed by the commutation relations demonstrated in Problems 4.3-4.6 (see also Section 3.6).

For given value of j the operator $\mathbf{J}$ acts in a $(2j+1)$-dimensional subspace of the $(2l+1)\,(2s+1)$-dimensional product space defined by the so-called *uncoupled basis* $\{|lm_l sm_s\rangle \equiv |lm_l\rangle \otimes |sm_s\rangle\}$. The sum of the $(2j+1)$-dimensional subspaces of all values of j allowed by the triangular inequality can also be represented by the so-called *coupled basis* $\{|lsjm_j\rangle\}$. The coupled and the uncoupled basis are related by a unitary transformation (see Problem 3.7).

Problem 4.3. Prove the following commutation relations $[\mathbf{L}^2, \mathbf{L}\cdot\mathbf{S}] = [\mathbf{S}^2, \mathbf{L}\cdot\mathbf{S}] = 0$.

Solution. Decomposing $\mathbf{L}\cdot\mathbf{S}$ we find $[\mathbf{L}^2, \mathbf{L}\cdot\mathbf{S}] = [\mathbf{L}^2, L_xS_x] + [\mathbf{L}^2, L_yS_y] + [\mathbf{L}^2, L_zS_z] = 0$ because $[\mathbf{L}^2, L_iS_i] = L_i[\mathbf{L}^2, S_i] + [\mathbf{L}^2, L_i]S_i = 0$ for $i \in \{x, y, z\}$. $[\mathbf{S}^2, \mathbf{L}\cdot\mathbf{S}] = 0$: Idem replacing $\mathbf{L}^2$ by $\mathbf{S}^2$. □

Problem 4.4. Prove the commutation relation $[J_z, \mathbf{L}\cdot\mathbf{S}] = 0$.

Solution. Decomposing $\mathbf{L}\cdot\mathbf{S}$ we find $[J_z, \mathbf{L}\cdot\mathbf{S}] = \frac{1}{2}[J_z, \mathbf{J}^2] - \frac{1}{2}[J_z, \mathbf{L}^2] - \frac{1}{2}[J_z, \mathbf{S}^2] = 0$ because $[J_z, \mathbf{J}^2] = 0$, $[J_z, \mathbf{L}^2] = [L_z + S_z, \mathbf{L}^2] = 0$ and $[J_z, \mathbf{S}^2] = [L_z + S_z, \mathbf{S}^2] = 0$. □

Problem 4.5. Prove the commutation relation $[\mathbf{J}^2, \mathbf{L}\cdot\mathbf{S}] = 0$.

Solution. Decomposing $\mathbf{J}^2$ we find $[\mathbf{J}^2, \mathbf{L}\cdot\mathbf{S}] = [\mathbf{L}^2, \mathbf{L}\cdot\mathbf{S}] + [\mathbf{S}^2, \mathbf{L}\cdot\mathbf{S}] + 2[\mathbf{L}\cdot\mathbf{S}, \mathbf{L}\cdot\mathbf{S}] = 0$ because $[\mathbf{L}^2, \mathbf{L}\cdot\mathbf{S}] = [\mathbf{S}^2, \mathbf{L}\cdot\mathbf{S}] = 0$ (see Problem 4.3) and $[\mathbf{L}\cdot\mathbf{S}, \mathbf{L}\cdot\mathbf{S}] = (\mathbf{L}\cdot\mathbf{S})^2 - (\mathbf{L}\cdot\mathbf{S})^2 = 0$. □

Problem 4.6. Prove the commutation relations $[\mathbf{J}^2, \mathbf{L}^2] = [\mathbf{J}^2, \mathbf{S}^2] = 0$, where $\mathbf{J} = \mathbf{L} + \mathbf{S}$.

Solution. Decomposing $\mathbf{J}^2$ we find $[\mathbf{J}^2, \mathbf{L}^2] = [\mathbf{L}^2, \mathbf{L}^2] + [\mathbf{S}^2, \mathbf{L}^2] + 2[\mathbf{L}\cdot\mathbf{S}, \mathbf{L}^2] = 0$ since $[\mathbf{L}\cdot\mathbf{S}, \mathbf{L}^2] = 0$ (see Problem 4.3); further $[\mathbf{L}^2, \mathbf{L}^2] = 0$ (any scalar operator commutes with itself) and $[\mathbf{S}^2, \mathbf{L}^2] = 0$ because $\mathbf{S}$ and $\mathbf{L}$ operate in orthogonal vector spaces. $[\mathbf{J}^2, \mathbf{S}^2] = 0$: Idem replacing $\mathbf{L}^2$ by $\mathbf{S}^2$. □

Problem 4.7. Show that $[L_z, \mathbf{L}\cdot\mathbf{S}] \neq 0$ and $[S_z, \mathbf{L}\cdot\mathbf{S}] \neq 0$ although $[J_z, \mathbf{L}\cdot\mathbf{S}] = 0$.

Solution. Decomposing $\mathbf{L}\cdot\mathbf{S}$ we find (using the summation convention) $[L_z, \mathbf{L}\cdot\mathbf{S}] = [L_z, L_\nu S_\nu] = L_\nu[L_z, S_\nu] + [L_z, L_\nu]S_\nu = [L_z, L_\nu]S_\nu$. Because $[L_z, L_\nu] = 0$ for $\nu = z$ we have $[L_z, \mathbf{L}\cdot\mathbf{S}] = [L_z, L_x]S_x + [L_z, L_y]S_y = i\hbar(L_yS_x - L_xS_y) \neq 0$. Likewise, we find $[S_z, \mathbf{L}\cdot\mathbf{S}] = i\hbar(L_xS_y - L_yS_x) \neq 0$. □

4.4.2 Velocity-induced magnetic field

As is well-known from classical electrodynamics, a particle moving at velocity $\mathbf{v}$ in the presence of an electric field $\mathbf{E}$ experiences a velocity-induced magnetic field, which is given by

$$\mathbf{B} = (\mathbf{E} \times \mathbf{v})/c^2, \tag{4.98}$$

where c is the speed of light. This follows from a special-relativistic analysis in the limit where Lorentz contraction can be neglected (cf. Appendix D). Nonrelativistically, this result can also be obtained with the aid of the Biot and Savart law by considering the current resulting from the relative motion of the nucleus with respect to the electron. Taking the relativistic point of view, an electron orbiting at velocity $\mathbf{v}$ in the electric field $\mathbf{E}$ of a nucleus will experience the velocity-induced field and its spin magnetic moment will couple to it. This coupling is similar to the spin Zeeman coupling and is known as *spin-orbit coupling.* To estimate this coupling we note that the electric field of the nucleus at the position of the electron is given by

$$\mathbf{E} = -\boldsymbol{\nabla}\varphi(r) = -\frac{\mathbf{r}}{r}\frac{d\varphi(r)}{dr}, \tag{4.99}$$

where $\varphi(r)$ is the electromagnetic scalar potential of the nucleus. Substituting $\mathbf{L} = m_r(\mathbf{r} \times \mathbf{v})$ for the orbital angular momentum, the velocity-induced magnetic field can be written as

$$\mathbf{B}_L = -\frac{1}{m_r c^2}\frac{1}{r}\frac{d\varphi(r)}{dr}\mathbf{L}. \tag{4.100}$$

This expression holds for all *hydrogen-like atoms.* For *hydrogenic* atoms $\varphi(r)$ is a simple Coulomb potential. For *alkali-like* atoms the nuclear charge is screened by a spherical shell of *core electrons* (see Section 4.6 for a phenomenological introduction of screening phenomena). A way to account for the screening is to replace the Coulomb potential by a *screened Coulomb potential*[1]

$$\varphi(r) = \frac{e}{4\pi\varepsilon_0}\frac{Z_{nl}(r)}{r}, \tag{4.101}$$

where $e\,Z_{nl}(r)$ is called the *effective nuclear charge* for an electron (the *spectator electron*) in the nl shell at distance r from the nucleus. Close to the nucleus screening is absent, at large distance screening by the core electrons is maximal,

$$\lim_{r\to 0} Z_{nl}(r) = Z \quad \text{and} \quad \lim_{r\to\infty} Z_{nl}(r) = Z_c \equiv Z - Z_{ion}. \tag{4.102}$$

Here $e\,Z_c$ is called the *Rydberg charge* of the atom/ion of ionic charge $e\,Z_{ion}$. The Rydberg charge is the effective nuclear charge in the limit of perfect screening by the core electrons and is used for the description of atoms/ions excited to Rydberg states. For neutral atoms $Z_c = 1$, for a singly charged ion $Z_c = 2$, *etc.*. In the hydrogenic case screening is absent at all distances; i.e., $Z_{nl}(r) \equiv Z = Z_c$. Since the derivative of the scalar potential determines $\mathbf{B}_L$ it is convenient to introduce the *spin-orbit screening function* $\mathcal{Z}_{nl}(r)$,

$$\frac{d\varphi(r)}{dr} = \frac{e}{4\pi\varepsilon_0}\frac{1}{r^2}\left(r\frac{dZ_{nl}(r)}{dr} - Z_{nl}(r)\right) \equiv -\frac{e}{4\pi\varepsilon_0}\frac{\mathcal{Z}_{nl}(r)}{r^2}. \tag{4.103}$$

As long as $Z_{nl}(r)$ *decreases monotonically* with increasing r we have

$$\mathcal{Z}_{nl}(r) \equiv Z_{nl}(r) - r\,dZ_{nl}(r)/dr > 0, \tag{4.104}$$

with $\mathcal{Z}_{nl}(r) \equiv Z$ in the hydrogenic case (for any state $|\kappa\rangle$ of the electron).

Treating the nucleus heuristically as a homogeneously charged sphere of radius r_n and total charge Ze, the electric field $\mathbf{E}(r)$ corresponds to a Coulomb field, for $r \le r_n$ attenuated proportionally to r (see Fig. 4.2). Hence, the velocity-induced magnetic field can be written as

$$\mathbf{B}_L = \begin{cases} \mathcal{Z}_{nl}(r)\dfrac{\mu_0}{4\pi}\dfrac{e}{m_r}\dfrac{\mathbf{L}}{r^3} & \text{for } r > r_n \\[2ex] Z\dfrac{\mu_0}{4\pi}\dfrac{e}{m_r}\dfrac{\mathbf{L}}{r_n^3} & \text{for } r \le r_n, \end{cases} \tag{4.105}$$

where μ_0 is the *magnetic permeability of vacuum.*. Note that the finite core size prevents the divergence of the $\mathbf{E}$ and $\mathbf{B}$ fields for $r \to 0$. Classically, the field experienced by the electron as a result of its orbital motion at nuclear distance $r = a_0$ is *large*, as follows from the prefactor

$$\frac{\mu_0}{4\pi}\frac{e}{m_e}\frac{\hbar}{a_0^3} \simeq 12.517\ \text{T}. \tag{4.106}$$

Quantum mechanically we have to average over the orbital wavefunction, which results in a reduction of this field. Calculating the modulus of the velocity-induced magnetic field using first-order perturbation theory we obtain for an electron in the state $|\kappa\rangle = |nlm_l\rangle$

$$B_L = \sqrt{\langle nlm_l|\mathbf{B}_L^2|nlm_l\rangle} = \frac{\mu_0}{4\pi}\frac{e\hbar}{m_r}\langle\mathcal{Z}(r)/r^3\rangle_{nl}\sqrt{\langle lm_l|\,(\mathbf{L}/\hbar)^2\,|lm_l\rangle}. \tag{4.107}$$

---

[1] We restrict ourselves to centrally symmetric screening potentials.

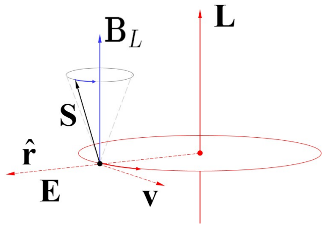

Figure 4.7: Vector diagram showing the precession cone of the electron spin **S** in the velocity induced field $\mathbf{B}_L$. Since the electron spin precesses in the same direction as the orbital motion **L** a reduced precession frequency is observed in the electron rest frame.

Turning to dimensionless quantities $\mathbf{L}/\hbar$ and $\rho = r/a$, with $a = (m_e/m_r)\, a_0$, and neglecting the finite size of the nucleus we obtain by substitution of Eqs. (2.49c) and (1.52) for the *hydrogenic* case

$$B_L = \begin{cases} \dfrac{\mu_0}{4\pi} \dfrac{e}{m_r} \dfrac{\hbar}{a^3} \dfrac{Z^4}{n^3} \dfrac{\sqrt{l(l+1)}}{(l+1)\,(l+1/2)\,l} & \text{for } l > 0 \\ 0 & \text{for } l = 0. \end{cases} \tag{4.108}$$

For $l > 0$ Eq. (4.108) is well-behaved. For instance, for the $2P$ level of hydrogen ($Z = 1,\ n = 2,\ l = 1$) we calculate $B_L \simeq 0.74$ T. For $l = 0$ the internal field tends to diverge but taking into account the nonzero nuclear size this divergence turns out to be an artifact of the pure Coulomb field. Using Eq. (4.105) (for $r < r_n$) the divergence is avoided and B_L turns out to be zero as a result of the angular averaging, $\langle 00|\, (\mathbf{L}/\hbar)^2\, |00\rangle = 0$.

4.4.3 Thomas precession

The velocity-induced field $\mathbf{B}_L$ results from the *rectilinear* motion of the electron and causes the electron spin to precess in its non-rotating rest frame,

$$(d\mathbf{S}/dt)_{nonrot} = \boldsymbol{\mu}_s \times \mathbf{B}_L = -g_e(e/2m_e)\mathbf{S} \times \mathbf{B}_L. \tag{4.109}$$

In view of Eq. (4.100) this precession proceeds about the direction of **L** (see Fig. 4.7). However, in the presence of angular momentum, the frame in which the linear motion is observed rotates at angular velocity $\boldsymbol{\omega}_T$. For weakly relativistic velocities this angular velocity is given by

$$\boldsymbol{\omega}_T = \frac{\mathbf{v} \times \mathbf{a}}{2c^2}, \tag{4.110}$$

where **a** is the acceleration and **v** the velocity in the laboratory-fixed frame. In the rest frame of the electron this manifests itself as *Thomas precession* [108, 110]. It is a purely kinematical effect, existing completely independently of other effects such as the Zeeman precession in a magnetic field. To account for the Thomas precession we have to transform to the rotating rest frame of the electron,

$$(d\mathbf{S}/dt)_{rest} = (d\mathbf{S}/dt)_{nonrot} - \boldsymbol{\omega}_T \times \mathbf{S}. \tag{4.111}$$

Substituting Eq. (4.109) we can write the precession rate in the form

$$(d\mathbf{S}/dt)_{rest} = -g_e(e/2m_e)\mathbf{S} \times \mathbf{B}_L + \mathbf{S} \times \boldsymbol{\omega}_T = -g_e(e/2m_e)\mathbf{S} \times \mathbf{B}_{LS}, \tag{4.112}$$

where

$$\mathbf{B}_{LS} = \mathbf{B}_L - \frac{\boldsymbol{\omega}_T}{g_e(e/2m_e)} \tag{4.113}$$

is the *effective internal field, the spin-orbit field* as experienced by the electron spin.

In the atom the acceleration is in radial direction,

$$\mathbf{a} = -\frac{1}{m_r}\boldsymbol{\nabla}\mathcal{V}(r) = \frac{e}{m_r}\frac{\mathbf{r}}{r}\frac{d\varphi(r)}{dr}. \tag{4.114}$$

Hence, the Thomas precession is given by

$$\boldsymbol{\omega}_T = -\frac{e}{2m_r^2c^2}\frac{1}{r}\frac{d\varphi(r)}{dr}\mathbf{L}. \tag{4.115}$$

For the spin-orbit field we find using Eqs. (4.113), (4.100), and (4.115)

$$\mathbf{B}_{LS} = -\left(1 - \frac{1}{g_e}\frac{m_e}{m_r}\right)\frac{1}{m_rc^2}\frac{1}{r}\frac{d\varphi(r)}{dr}\mathbf{L}. \tag{4.116}$$

Approximating $g_e m_r/m_e \simeq 2$ we notice that the Thomas precession reduces the spin-orbit field by as much as 50%.

4.4.4 Spin-orbit interaction

Substituting the expression for the spin-orbit field (4.116) into the spin-Zeeman Hamiltonian (4.84) we obtain the Hamiltonian describing the *spin-orbit interaction*

$$\mathcal{H}_{LS} = -\boldsymbol{\mu}_s \cdot \mathbf{B}_{LS} = g_e(e/2m_e)\mathbf{S}\cdot\mathbf{B}_{LS} = \xi(r)\mathbf{L}\cdot\mathbf{S}. \tag{4.117}$$

This Hamiltonian expresses the coupling between **L** and **S** (*spin-orbit coupling*). The function $\xi(r)$ is the *coupling strength*,

$$\xi(r) = -\frac{(g_e'-1)}{2m_r^2c^2}\frac{e}{r}\frac{d\varphi(r)}{dr} = \begin{cases} \xi_0\dfrac{\mathcal{Z}_{nl}(r)}{r^3} & \text{for } r > r_n \\ \xi_0\dfrac{Z}{r_n^3} & \text{for } r \leq r_n, \end{cases} \tag{4.118}$$

where the prefactor can be written in various equivalent forms,

$$\xi_0 \simeq \frac{1}{2m_r^2c^2}\frac{e^2}{4\pi\varepsilon_0} = \frac{\mu_0}{4\pi}2\gamma_L^2 = \frac{1}{2}\alpha^4 m_r c^2\frac{a^3}{\hbar^2}, \tag{4.119}$$

as follows by approximating $g_e' = g_e m_r/m_e \simeq 2$ and the use of Eqs. (4.54), (2.11) and (2.13). Importantly, we note that $\xi(r) > 0$ if $\mathcal{Z}_{nl}(r) > 0$.

4.4.5 Fine structure Hamiltonian for hydrogen-like atoms

We are now in a position to write down the Hamiltonian for the magnetic fine structure of hydrogen-like atoms; i.e., for an electron, of charge $q = -e$ and intrinsic magnetic moment $\boldsymbol{\mu}_s$, moving in the central field of the atomic nucleus and in the presence (or absence) of an externally applied magnetic field,

$$\mathcal{H} = -\frac{\hbar^2}{2m_r}\Delta + \mathcal{V}(r) + \mathcal{H}_r - \frac{i\hbar e}{m_r}(\mathbf{A}\cdot\boldsymbol{\nabla}) + \frac{e^2}{2m_r}\mathbf{A}^2 - \boldsymbol{\mu}_s\cdot(\mathbf{B}+\mathbf{B}_{LS}). \tag{4.120}$$

This expression holds in the Coulomb gauge, $\boldsymbol{\nabla}\cdot\mathbf{A} = 0$. From left to right we recognize first the Schrödinger Hamiltonian $\mathcal{H}_0$ and its relativistic correction $\mathcal{H}_r$, the $\mathbf{A}\cdot\boldsymbol{\nabla}$ term describes the motion of the electron in the vector potential of an externally applied magnetic field **B** (for a homogeneous field $\mathbf{A} = \frac{1}{2}\mathbf{B}\times\mathbf{r}$). The last term is the spin Zeeman coupling, involving both the external field **B** and the spin-orbit field $\mathbf{B}_{LS}$. We start by considering the atom in the absence of an external field ($\mathbf{B} = 0$); i.e., for a vanishing vector potential ($\mathbf{A} = 0$). In Section 4.7 we discuss fine structure in the presence of an external field ($\mathbf{B} \neq 0$).

4.5 Fine structure in zero field

4.5.1 Effective Hamiltonian and spin-orbit splitting

In the absence of external fields the fine-structure Hamiltonian (4.120) reduces to the form

$$\mathcal{H} = \mathcal{H}_0 + \mathcal{H}_r + \xi(r)\mathbf{L}\cdot\mathbf{S}, \tag{4.121}$$

where $\mathcal{H}_0$ is the Schrödinger Hamiltonian and $\mathcal{H}_r$ stands for the relativistic correction. The spin-orbit interaction causes the n^2-fold degeneracy of the principal atomic structure to be lifted in zero field. This is called *spin-orbit splitting* and is illustrated for ${}^2P$ terms in Fig. 4.8. Since $\xi(r)$ does not commute with $\mathcal{H}_0$ and $\mathcal{H}_r$, the spin-orbit interaction couples states of different principal quantum number. Hence, to calculate the splitting, we have to turn to perturbation theory (of a degenerate level). Fortunately, both $\xi(r)$ and $\mathbf{L}\cdot\mathbf{S}$ commute with $\mathbf{L}^2$, $\mathbf{S}^2$, $\mathbf{J}^2$ and J_z (see Problems 4.3, 4.4, 4.5 and 4.6). This makes the spin-orbit interaction *diagonal* in the coupled angular momentum basis, $\{|lsjm_j\rangle\}$; i.e., l, s, j and m_j are good quantum numbers. Since l remains a good quantum number, the *parity* of the angular momentum state is not affected by the spin-orbit interaction. For a manifolds of given n, the spin-orbit shift can be calculated using the well-known expression (H.56) from ordinary first-order perturbation theory,[1]

$$\Delta E_{n,j}^{LS} = \langle nlsjm_j|\mathcal{H}_{LS}|nlsjm_j\rangle = (\zeta_{nl}/\hbar^2)\langle lsjm_j|\mathbf{L}\cdot\mathbf{S}|lsjm_j\rangle, \tag{4.122}$$

where ζ_{nl} is a radial integral known as the *spin-orbit coupling constant*,

$$\zeta_{nl} = \langle\xi(r)\rangle_{nl}\hbar^2 = \begin{cases} \frac{1}{2}\alpha^4 m_r c^2\langle\mathcal{Z}(r)/\rho^3\rangle_{nl} & \text{for } l>0 \\ \text{finite} & \text{for } l=0. \end{cases} \tag{4.123}$$

The divergence expected for the $l=0$ radial integral is avoided ($\zeta_{nl}=$ finite) provided we account for the nonzero nuclear size. The coupling constant has the properties of a so-called reduced matrix element: it depends on the quantum numbers n and l but not on m_l (see Problem 2.2). Its numerical value is *positive* ($\zeta_{nl}>0$) in hydrogen-like atoms. In *many-electron* atoms the coupling constant can also become negative (see Section 10.6.5). The radial integral $\langle\mathcal{Z}(r)/r^3\rangle_{nl}$ can be determined numerically but generally not without a substantial effort because the determination of $\mathcal{Z}_{nl}(r)$ requires knowledge of the effective charge distribution and this in turn depends on the screening. On the other hand, using the spin-orbit shift rules (see Section 4.5.2 below), it is straightforward to determine the integral experimentally from a measurement of the spin-orbit splitting in zero magnetic field.

In view of the discussion above it is convenient to write the atomic Hamiltonian in the following approximate form,

$$\mathcal{H} = \mathcal{H}_0 + \mathcal{H}_r + (\zeta_{nl}/\hbar^2)\mathbf{L}\cdot\mathbf{S}, \tag{4.124}$$

where the numerical constant ζ_{nl} is defined by Eq. (4.123). Eq. (4.124) is an *effective fine-structure Hamiltonian* that holds for given values of the quantum numbers n and l. It has the advantage over Eq. (4.121) that it offers the possibility to determine ζ_{nl} experimentally as a phenomenological constant. Importantly, for the last term of the Hamiltonian (4.124) not only l but also n is a good quantum number. This is an approximation: calculations based on Eq. (4.124) are equivalent with calculations based on the actual Hamiltonian (4.121) as long as the principal structure of the atom is accounted for only to first order in perturbation theory. This is a good approximation as long the fine-structure splitting of a level of given n is small compared to the principal-level splitting, which is the case for $\zeta_{nl} \ll E_{n+1} - E_n$. As this condition is satisfied in many practical cases, we shall use the effective Hamiltonian (4.124) to describe the fine structure of hydrogen-like atoms.

---

[1] The coupling to different n levels enters only to second or higher order in perturbation theory. In first order only the states within the manifold *of given* n contribute (n is a good quantum number to first order in perturbation theory - see Appendix H.3).

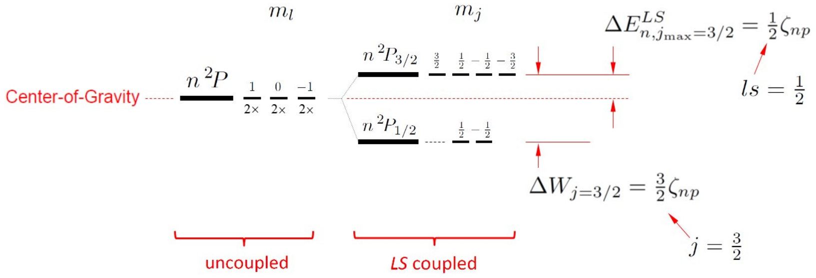

Figure 4.8: Fine-structure splitting for a $n\,^2P$ Term ($l = 1,\ s = \frac{1}{2}$). Shown are the unperturbed level as well as the spin-orbit splitting into the $n\ ^2P_{3/2}$ (*stretched*) and $^2P_{1/2}$ manifolds. The splitting is drawn for the *regular* (hydrogen-like) case ($\zeta_{np} > 0$). Note that the *center-of-gravity* of the levels is conserved in the splitting. The magnitude of the splitting, ΔW_j, satisfies with the *Landé interval rule.*

4.5.2 Shift rules for spin-orbit coupling in zero field

Using the operator identity

$$\mathbf{L}\cdot\mathbf{S} = \tfrac{1}{2}(\mathbf{J}^2 - \mathbf{L}^2 - \mathbf{S}^2) \tag{4.125}$$

the *spin-orbit shift* of the LS manifold with quantum number j evaluates to

$$\Delta E^{LS}_{n,j} = \tfrac{1}{2}\zeta_{nl}\left[j(j+1) - l(l+1) - s(s+1)\right]. \tag{4.126}$$

Note that for *positive* coupling constant ($\zeta_{nl} > 0$) the energy of the LS manifolds increases with j. This is called *regular* (i.e., hydrogen-like) ordering of the j levels; for $\zeta_{nl} < 0$ the order of the j levels is called *inverted*. The manifold of highest multiplicity ($j = j_{\max} = l + s$) corresponds to the so called *stretched state* of the LS coupling scheme. From Eq. (4.126) we derive *three shift rules* for the spin-orbit manifolds of given j, l and s (see Fig. 4.8):

- the shift of the *stretched state* ($j = j_{\max} = l + s$) is given by

$$\Delta E^{LS}_{n,j_{\max}} = \zeta_{nl} ls. \tag{4.127}$$

- the relative shift of two adjacent j manifolds follows the *Landé interval rule*:

$$\Delta W_j = \Delta E^{LS}_{n,j} - \Delta E^{LS}_{n,j-1} = \zeta_{nl} j_>, \tag{4.128}$$

  where $j_>$ is the quantum number of the manifold with the highest multiplicity of *adjacent pairs*, $j_> = max(j, j-1)$.

- the weighted mean of the energies of *all j manifolds* of a given LS coupling scheme coincides with the energy of the $(2l + 1)\,(2s + 1)$-fold degenerate unperturbed level (see Problem 4.8),

$$\frac{1}{(2l+1)\,(2s+1)} \sum_{j=|l-s|}^{l+s} (2j+1)\,\Delta E^{LS}_{n,j} = 0. \tag{4.129}$$

  This is called the *center-of-gravity rule.*

The fine structure of all *hydrogen-like* atoms is determined by the angular momentum properties of a single electron. Hence, the electronic states are *electron spin doublets* ($s = \frac{1}{2}$) of varying orbital angular momentum. To facilitate verbal discussion the manifolds are usually referred to in the *Term* notation; e.g., $1\,^2S,\ 2\,^2P,\ 3\,^2D$, etc..[1] In doublet terms the coupling of the spin to the orbital angular

---

[1] In the most general context a *Term* is defined as a manifold of states spanning the angular momentum subspace of given L and S; for hydrogen-like atoms $L = l$ and $S = s = \frac{1}{2}$.

momentum can result in only two values of total angular momentum: $j = l + \frac{1}{2}$ (parallel coupling; e.g., $n\,{}^2P_{3/2}$) and $j' = l - \frac{1}{2}$ (anti-parallel coupling; e.g., $n\,{}^2P_{1/2}$). For these two cases we have

$$\Delta E^{LS}_{n,j} = \begin{cases} +\frac{1}{2}\zeta_{nl} l & (j = l + \frac{1}{2}) \\ -\frac{1}{2}\zeta_{nl}(l+1) & (j = l - \frac{1}{2}) \end{cases} \text{ for } l > 0 \\ 0 \qquad \text{for } l = 0. \tag{4.130}$$

Note in this example that for hydrogen-like atoms ($\zeta_{nl} > 0$) the state with the highest multiplicity has indeed the highest energy (as mentioned above). Note further that the interval rule holds,

$$\Delta W_{l+1/2} = \Delta E^{LS}_{n,l+1/2} - \Delta E^{LS}_{n,l-1/2} = \zeta_{nl}(l + \tfrac{1}{2}). \tag{4.131}$$

The sum of the level shifts is given by

$$\Delta E^{LS}_{n,l+1/2} + \Delta E^{LS}_{n,l-1/2} = -\zeta_{nl}/2 \tag{4.132}$$

and the center of gravity of the levels is indeed zero,

$$(2l+2)\,\zeta_{nl} l/2 - 2l\zeta_{nl}\,(l+1)\,/2 = 0. \tag{4.133}$$

Problem 4.8. Show that the center of gravity of the fine-structure manifold coincides with the energy of the unperturbed level.

Solution. Note that the trace is independent of the choice of representation,

$$\mathrm{tr}\,(\mathcal{H}'_{LS}) = \mathrm{tr}\,\left(U^{-1}\mathcal{H}_{LS}U\right) = \mathrm{tr}\,\left(UU^{-1}\mathcal{H}_{LS}\right) = \mathrm{tr}\,(\mathcal{H}_{LS})\,,$$

where U is a unitary transformation between the two bases and we used (in the second step) the matrix property (M.26) that the trace of a product of operators is invariant under cyclic permutation of the operators. Rather than working in the coupled basis $\{|nlsjm_j\rangle\}$ we choose the uncoupled basis $\{|nlm_lsm_s\rangle\}$ to calculate the trace (4.129),

$$\mathrm{tr}\,(\mathcal{H}_{LS}) = \sum_{m_s=-s}^{s}\sum_{m_l=-l}^{l}(\zeta_{nl}/\hbar^2)\langle lm_lsm_s|\mathbf{L}\cdot\mathbf{S}|lm_lsm_s\rangle.$$

Using the inner product rule (3.159b) and noting that only the L_zS_z terms are diagonal we find

$$\mathrm{tr}\,(\mathcal{H}_{LS}) = \sum_{m_s=-s}^{s}\sum_{m_l=-l}^{l}\zeta_{nl}m_lm_s = 0.$$

For the center of gravity we have to normalize on the $(2l+1)\,(2s+1)$-fold degeneracy of the unperturbed level but obviously this does not change the result if the center of gravity is zero. □

4.5.3 Fine structure of hydrogenic atoms

For the special case of *hydrogenic* atoms the orbital integrals can be solved analytically. Setting $\mathcal{Z}_{nl}(r) \equiv Z$ in Eq. (4.118) we obtain for the coupling strength

$$\xi(r) = \tfrac{1}{2}\alpha^4 m_r c^2 \frac{a^3}{r^3}\frac{Z}{\hbar^2}. \tag{4.134}$$

Hence, the coupling constant follows from Eq. (4.123)

$$\zeta_{nl} = \begin{cases} \frac{1}{2}\alpha^4 m_r c^2 Z\,\langle\rho^{-3}\rangle_{nl} & \text{for } l > 0 \\ \text{finite} & \text{for } l = 0. \end{cases} \tag{4.135}$$

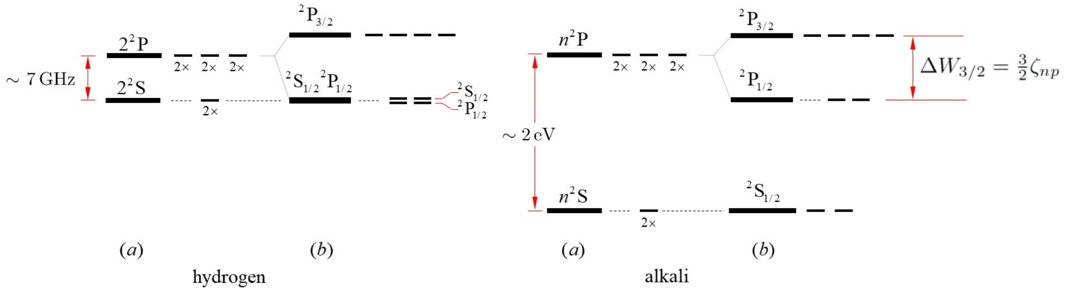

Figure 4.9: Term diagram showing the difference in fine structure between hydrogen and alkali-like atoms: (a) without spin-orbit splitting, (b) with spin-orbit splitting. The hydrogen fine structure is characterized by two levels with a splitting of only ~ 7 GHz, whereas in the alkali case one observes three levels and the splitting is much larger (~ 2 eV). These differences originate in the absence or presence of screening of the nuclear charge by core electrons (which is less effective for s electrons than for p electrons).

Evaluating the radial integral, see Eqs. (2.49), this becomes

$$\zeta_{nl} = \begin{cases} \frac{1}{2}\alpha^4 m_r c^2 \dfrac{Z^4}{n^3} \dfrac{1}{l(l+1/2)(l+1)} = -\dfrac{\alpha^2 Z^2}{n} E_n \dfrac{1}{l(l+1/2)(l+1)} & \text{for } l > 0 \\ \text{finite} & \text{for } l = 0, \end{cases} \tag{4.136}$$

where E_n is the zero-order energy given by Eq. (2.33); for $l = 0$ we took into account the finite nuclear size. Thus, using Eq. (4.131) we find for the *fine structure splitting*

$$\Delta W_{l+1/2} = -\frac{\alpha^2 Z^2}{n} E_n \frac{1}{l(l+1)} = \frac{\alpha^2 Z^4}{2n^3} \frac{1}{l(l+1)} \text{ Hartree} \quad \text{for } l > 0. \tag{4.137}$$

The numerical value of the splitting is ~ 11 GHz. Using Eqs. (4.130) we find for the level shifts

$$\Delta E_{n,j}^{LS} = \begin{cases} \left.\begin{matrix} -\dfrac{\alpha^2 Z^2}{n^2} E_n \dfrac{n}{(l+1/2)(l+1)} \dfrac{1}{2} & (j = l + \frac{1}{2}) \\ +\dfrac{\alpha^2 Z^2}{n^2} E_n \dfrac{n}{l(l+1/2)} \dfrac{1}{2} & (j = l - \frac{1}{2}) \end{matrix}\right\} & \text{for } l > 0 \\ 0 & \text{for } l = 0. \end{cases} \tag{4.138}$$

Remarkably, adding Eqs. (4.24) and (4.138) brings us a *single* expression for the *fine-structure shift* which depends on only two quantum numbers (n, j) rather that three (n, l, s),

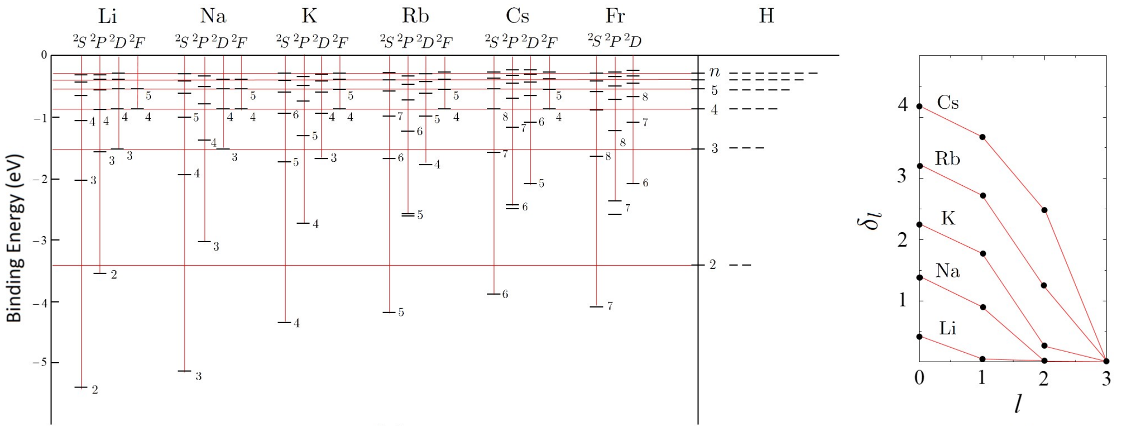
$$\Delta E_{n,j} = \Delta E_n^{\text{rel}} + \Delta E_n^{LS} = -E_n \frac{\alpha^2 Z^2}{n^2} \left(\frac{3}{4} - \frac{n}{j + 1/2} \right). \tag{4.139}$$

For $j = \frac{1}{2}$ this expression corresponds to the $l = 0$ relativistic shift of Eq. (4.24) whereas for $j = l \pm \frac{1}{2}$ it gives the fine-structure splitting for $l > 0$. Interestingly, the value $j = \frac{1}{2}$ is obtained for $l = 0$ but also for $l = 1$ (using $j = l - \frac{1}{2}$). This results in an "accidental" degeneracy of the $^2P_{1/2}$ and $^2S_{1/2}$ levels in hydrogenic atoms but is absent in the hydrogen-like atoms at large.

4.6 Fine structure of alkali-like atoms in zero field

4.6.1 Introduction

Historically, the accidental degeneracy of the $2^2P_{1/2}$ and $2^2S_{1/2}$ levels in hydrogen played an important role in the development of quantum mechanics. In atomic spectroscopy this degeneracy



(*a*) (*b*)

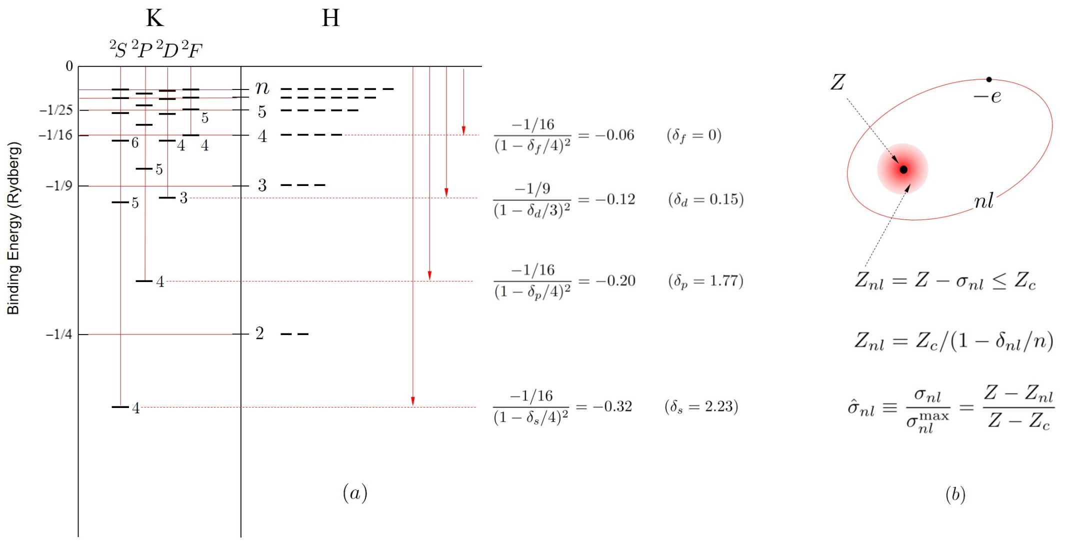
Figure 4.10: (*a*) Energy levels of the alkali atoms for different states of the *valence electron* next to those of hydrogen. The data are taken from the NIST Atomic Spectra Database Levels Data [66]. Note that the binding energies in the alkali atoms remain close to those of the hydrogenic electron in spite of enormous differences in nuclear charge. In particular, for $l \to \infty$ and/or $n \to \infty$ the levels converge to those of H. This similarity is the result of screening of the nuclear charge by the core electrons. In the data for Rb, Cs and Fr the fine-structure splitting of the $5\,^2P$, $6\,^2P$ and $7\,^2P$ terms becomes resolved on the eV energy scale of the diagram. (*b*) Quantum defect plot of the same data [28]. Note that for $l \geq 3$ the alkali atoms behave hydrogenic; i.e., the screening by the core electrons is perfect. Furthermore, for a given atomic species the quantum defect is independent of the principal quantum number, $\delta_{nl} \simeq \delta_l$.

manifests itself as a fine-structure splitting into *two* levels ($^2P_{3/2}$ and $^2P_{1/2}/^2S_{1/2}$, not considering the small Lamb shift). In alkali atoms this degeneracy is absent and *three* levels are observed ($^2P_{3/2}$, $^2P_{1/2}$ and $^2S_{1/2}$). Furthermore, as illustrated in Fig. 4.9, the $2\,^2S$-$2\,^2P$ splitting in hydrogen is only $\sim 7\,\mathrm{GHz}$ (see Section 4.1.2) whereas in the alkalies it is $\sim 2\,\mathrm{eV}$, more than four orders of magnitude larger. In hindsight, these differences had to be understood before the electron spin could be postulated [112]. It slowed down progress and became a great scientific puzzle: why is it that two quantum numbers suffice to describe hydrogen (n, j) but a third one is required for the alkalies (n and l and s)?

To understand the alkali atoms we have to understand the physics of *screening by core electrons*. Core electrons are present in the alkalies but absent in the hydrogenic case. Our approach will be mostly phenomenological. Starting from the experimental values in the NIST Atomic Level Database [66] we develop a qualitative picture of the atomic structure in which *electron shells* provide the underpinning of the *periodic system of the elements*. This means that we shall temporarily jump ahead, using features from the physics of many-electron atoms for which the theory will be presented in Chapters 7 through 10. After discovering the enormous impact of the core on the principal structure of the atom (Section 4.6.2) we turn in section 4.6.3 to the consequences for spin-orbit coupling. Throughout the discussion of screening Hartree atomic units will be used.

4.6.2 Screening by core electrons - effect on principal structure

Alkali and alkali-like atoms differ from hydrogenic atoms by the presence of *core electrons*. As will be shown in Section 10.3 the electron core is spherical, so it does not affect the central symmetry of the atom; i.e., the rotational structure is not affected. In contrast, the radial structure changes dramatically as the core electrons seriously modify the charge distribution within the atom. It may speak for itself that this affects the radial distribution function of the orbitals with immediate consequences for the binding energies of the electrons.



(a)

(b)

Figure 4.11: (a) Energy levels of *potassium* (K) compared to those of hydrogen. The *deviations from the hydrogenic values* are quantified by the quantum defects δ_s, δ_p, δ_d and δ_f; (b) Quantum defects result from incomplete screening of the nucleus by core electrons. This manifests itself as an *effective nuclear charge*, $Z_{nl} = Z - \sigma_{nl}$ (the *nuclear charge* Z lowered by the *screening constant* σ_{nl}). In the Rydberg limit the screening is maximal ($Z_{nl} = Z_c$) and the *screening efficiency* $\hat{\sigma}_{nl} \equiv \sigma_{nl}/\sigma_{nl}^{\max}$ becomes unity. The relation between δ_{nl} and Z_{nl} (and σ_{nl}) follows by equating Eqs. (4.143) and (4.141) for the same energy level.

To introduce the phenomenology of screening we show in Fig. 4.10a and Fig. 4.11a the energy levels of the valence electron in alkali atoms next to those of hydrogen.[1] The levels are labeled by the principal quantum number (n) for given value of the angular momentum (s, , p, d, $\cdots$). Note that the alkali levels cover roughly the same range of energies as those of hydrogen in spite of the enormous difference in nuclear charge: $Z = 1$ in *hydrogen* (H) and $Z = 87$ in *francium* (Fr). This points to efficient *screening* of the nucleus by the core electrons. The key idea is illustrated for *potassium* (K) in Fig. 4.11b. The electron core acts as a cloud of negative charge in-between the nucleus and the valence electron. In classical electrodynamics such a charge distribution is called *space charge.* In quantum mechanics the space charge arises as a *mean field* of negative charge distributed according to the probability density of the electronic orbitals (see Fig. 4.12). This mean field lowers the electrostatic potential around the nucleus, thus giving rise a screened Coulomb potential with (in atomic units) an *effective nuclear charge* $Z_{nl}(r)$ as introduced in Section 4.4.2.

4.6.2.1 Screening constant and efficiency versus quantum defect

In the simplest description of screening, for each orbital nl the amount of screening is specified by a single number, the *screening constant* σ_{nl}. For an atom of nuclear charge Z, the screening constant is related to the *effective nuclear charge,*

$$Z_{nl} \equiv Z - \sigma_{nl}. \tag{4.140}$$

As a *rule of thumb,* σ_{nl} equals the number of core electrons involved in the screening. So, we expect: $Z_{1s} \simeq Z$ (no core) $Z_{2s} \simeq Z - 2$ ($1s^2$ core), $Z_{2p} \simeq Z - 4$ ($1s^2 2s^2$ core), $Z_{3s} \simeq Z - 10$ ($1s^2 2s^2 2p^6$ core), $Z_{3p} \simeq Z - 12$ ($1s^2 2s^2 2p^6 3s^2$ core), etc.. In terms of Z_{nl} the energies of the principal structure

---

[1] Beware that we focus on the similarities between the behavior of the *valence* electron in the alkalies and the hydrogenic electron of the Bohr atom. Core electron excitations are *not included* in this diagram.

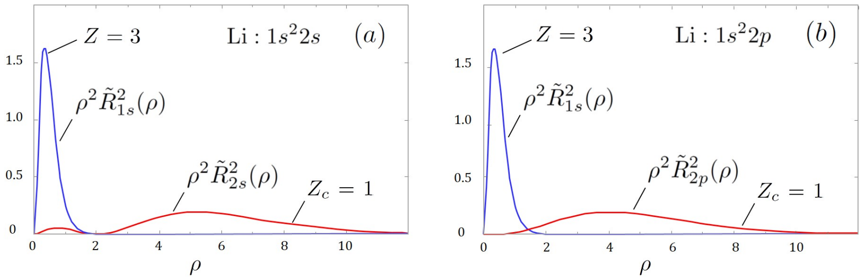


Figure 4.12: Radial distribution functions of hydrogenic wavefunctions give an impression of the electronic charge distribution. In the *lithium* atom (Li) the $1s$ orbital is a core orbital which is drawn for the unscreened nuclear charge ($Z = 3$). We compare two valence electrons, both drawn for $Z = Z_c = 1$: (a) the $2s$ electron penetrates deeply into the core which points to poor screening from the nucleus; (b) the $2p$ electron hardly penetrates into the core. This points to close to perfect screening. Note that screening corrections giving rise to deviations from the hydrogenic shape are not included in this plot.

are given by

$$\varepsilon_{nl} = -\frac{Z_{nl}^2}{2n^2}. \tag{4.141}$$

Note that binding energy of the valence electron scales quadratically with Z_{nl}/n.

Another way of characterizing screening is by specification of the *quantum defect* δ_{nl} (also known as *Rydberg correction*). This quantity turns the principal quantum number, the integer n, into an *effective principal quantum number*, the positive real number

$$n_l^* = n - \delta_{nl}. \tag{4.142}$$

The quantum defect is a measure for the deviation from the hydrogenic distribution of levels. A list of quantum defects for *valence electron levels* in alkali atoms is given in Table 4.1. Note that, for a given alkali species, δ_{nl} shows little dependence on the principal quantum number, $\delta_{nl} \simeq \delta_l > 0$. On the other hand δ_l decreases rapidly with l as is illustrated in Fig. 4.10b. Hence, by measuring a few quantum defects (δ_s, δ_p, δ_d, $\cdots$) the whole level diagram can be reconstructed using the Bohr formula for the binding energies but with n_l^* replacing n,

$$\varepsilon_{nl} = -\frac{Z_c^2}{2n_l^{*2}} = -\frac{Z_c^2}{2n^2}\frac{1}{(1-\delta_l/n)^2}. \tag{4.143}$$

Here Z_c stands for the *Rydberg charge* introduced in Section 4.4.2; for neutral atoms $Z_c = 1$, for singly charged ions $Z_c = 2$, *etc.*.

Interestingly, for $n \gg 1$ the ratio of the level shift (with respect to the hydrogenic value) over the level separation value goes to a constant. The limiting value is called the *Rydberg limit*. This limit can be determined by expanding Eq. (4.143) to leading order in powers of δ_{nl}/n. For the *level shift* with respect to the hydrogenic value we find

$$\delta\varepsilon_{nl} = \frac{Z_c^2}{n^3}\delta_{nl} + \cdots \quad (n \gg 1). \tag{4.144}$$

Since $\delta_{nl} \simeq \delta_l$ for $n \gg 1$, the *level separation*, $\Delta\varepsilon_{nl} \equiv \varepsilon_{(n+1)l} - \varepsilon_{nl}$, is given by

$$\Delta\varepsilon_{nl} = \frac{Z_c^2}{2(n-\delta_l)^2} - \frac{Z_c^2}{2(n+1-\delta_l)^2} = \frac{Z_c^2}{n^3} + \cdots \quad (n \gg 1). \tag{4.145}$$

In the *Rydberg limit* the ratio $\delta\varepsilon_{nl}/\Delta\varepsilon_{nl}$ converges to the quantum defect,

$$\lim_{n\to\infty} \frac{\delta\varepsilon_{nl}}{\Delta\varepsilon_{nl}} = \delta_l. \tag{4.146}$$

Table 4.1: Fine-structure-avaraged quantum defects for selected atomic energy levels. The table is based on the NIST Atomic Spectra Database Levels Data [66]. Metastable helium (He*) will be discussed in Section 7.4.4.

The screening constant is a good absolute measure for screening but often a relative measure is desired. As maximal screening is obtained for valence electrons in the Rydberg limit,

$$\sigma_{nl} = Z - Z_{nl} \leq Z - Z_c \equiv \sigma_{nl}^{\max},$$

a good relative measure for the screening is the *screening efficiency*, defined as

$$\hat{\sigma}_{nl} \equiv \sigma_{nl}/\sigma_{nl}^{\max} = (Z - Z_{nl})/(Z - Z_c). \tag{4.147}$$

This quantity varies from 0 in the absence of screening to 1 for perfect screening. The screening efficiencies for the valence electron of the alkali atoms are included in Table 4.1. For the ground state of *lithium* (Li), with only two screening electrons, it is 87%. For all other alkali states the screening is over 90% and increases with increasing values of n and l. The latter does not come as a surprise because for large n and l the valence electron resides at larger distances from the nucleus and the charge overlap with the electron core will be small.

The relation between the effective nuclear charge, Z_{nl}, and the quantum defect, δ_{nl}, follows by equating Eqs. (4.141) and (4.143),

$$Z_{nl} = Z_c/(1 - \delta_{nl}/n). \tag{4.148}$$

Since ε_{nl} scales quadratically with Z_{nl}/n the levels become hydrogenic (with respect to Z_c) for $n \gg 1$. Furthermore, since δ_l decreases for increasing l the binding energy also becomes hydrogenic for $l \gg 1$. This means that, for large l and/or n, the screening of the nucleus by the core electrons becomes close to perfect and the energy levels can be calculated by replacing Z with Z_c in the Bohr formula. In Section 8.3.3.1 a simple screened Coulomb potential is constructed which shows the absence of a dependence on n (for given Z) as well as the decline of screening with increasing l. At the advanced level, the quantum defect is a key element in the theory of *Rydberg atoms* [47].

In terms of the quantum defect the screening efficiency is given by

$$\hat{\sigma}_{nl} = 1 - \frac{Z_c}{Z - Z_c} \frac{\delta_{nl}/n}{1 - \delta_{nl}/n}. \tag{4.149}$$

This expression shows that, for given Z, Z_c and n, a smaller quantum defect corresponds to better screening efficiency, with the screening becoming perfect for $l \gg 1$ and/or $n \gg 1$. When comparing configurations differing in Z and Z_c and/or n, the correspondence is not so intuitive. For the neutral *lithium* (Li) atom and the *calcium ion* (Ca^+) in the same electron configuration, the same screening efficiency is obtained for a smaller quantum defect in the ion (see Problem 4.9).

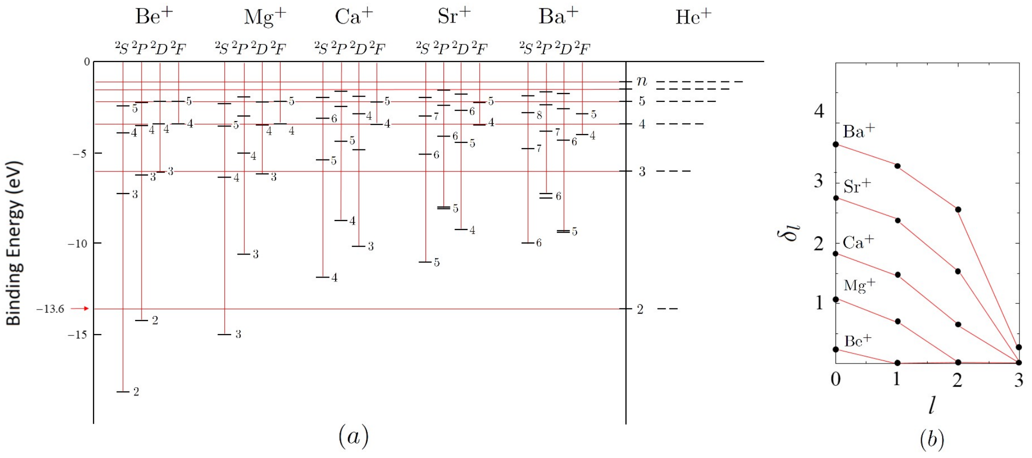

Figure 4.13: (a) Energy levels of the alkaline-earth ions for different states of the *valence electron* next to those of hydrogenic helium. The data are taken from the NIST Atomic Spectra Database Levels Data [66]. Note that the binding energies remain close to that of the hydrogenic electron in He$^+$ as the result of screening by the core electrons. In particular, for $l \to \infty$ and/or $n \to \infty$ the levels converge to those of He$^+$; (b) Quantum defect plot of the same data. For $l \geq 3$ the ions behave hydrogenic; i.e., the screening by the core electrons is maximal. Note the close similarity with Fig. 4.10; i.e., the alkaline-earth ions behave alkali like. A qualitative difference with the alkali atoms is the appearance of the *metastable* ^2D levels in Ca$^+$, Sr$^+$ and Ba$^+$ which can be used to create optical qubits for quantum information processing [98].

4.6.2.2 The phenomenology of screening

Equipped with the tools for characterizing the screening we are prepared to analyze the level diagrams of Fig. 4.10. We start with the example of *lithium* (Li). In this case we have $Z = 3$ and the valence electron is screened from the nucleus by the $1s^2$ core ($\sigma_{nl} \simeq 2$, for $n \geq 2$). Hence, for perfect screening we expect for the effective nuclear charge $Z_{nl} = Z - \sigma_{nl} \simeq Z_c = 1$. The experimental values are found in Table 4.1. Apparently, the screening is close to perfect for the $2p$, $3p$ and $3d$ orbitals ($Z_{nl} \simeq 1$) but incomplete for the $2s$ and $3s$ orbitals. This is consistent with the mean field picture because s orbitals extend all the way to the nucleus (where screening is negligible), whereas orbitals with higher angular momenta (p, d, $f, \cdots$) fall off towards the characteristic central node (see Section 2.3). As illustrated in Fig. 4.12, the radial distribution of the $2p$ electron surrounds the $1s$ core like a halo whereas the $2s$ electron electron has a sizable overlap with the core. This points to incomplete screening for the $2s$ electron which explains the stronger binding in Fig. 4.10. As visible in Fig. 4.9 the corresponding difference in binding energy is typically 2 eV for the alkalies.

This *preferential binding of electrons in s orbitals* (or better: low-l orbitals) becomes manifest when studying the level ordering for the entire group of alkalies in Fig. 4.10. In hydrogenic atoms the binding energy decreases with increasing principal quantum number but this ordering is lost in the heavier alkalies. In the case of Na the binding of the $4s$ orbital is stronger than that of the $3d$ orbital ($\varepsilon_{4s} < \varepsilon_{3d}$), for K this becomes $\varepsilon_{4s}, \varepsilon_{4p} < \varepsilon_{3d}$ and even $\varepsilon_{5s} < \varepsilon_{3d}$. These *deviations from the hydrogenic ordering* have important consequences for the ground state configurations of the alkali atoms and, more in general, for the structure of the periodic system (cf. Chapter 10).

What would happen to the screening if we could increase the nuclear charge? It may speak for itself that the atom would contract but is the ordering of the energy levels affected? Questions like this can be answered by studying the level diagram of the singly ionized alkaline-earth ions shown in Fig. 4.13. These ions are *isoelectronic* (i.e., have the same number of electrons) with the adjacent alkali atom in the periodic system but the nuclear charge has increased from Z in the atom to $Z^+ = Z + 1$ in the ion. In the simplest model for screening also the effective nuclear charge

increases by one: $Z_{nl}^+ \simeq Z_{nl}+1$. The corresponding *relative* increase, $Z_{nl}^+/Z_{nl} = (Z_{nl}+1)/Z_{nl}$, is largest for the outer orbitals because Z_{nl} *falls off* towards Z_c in the Rydberg limit,

$$Z_c^+/Z_c > Z_{nl}^+/Z_{nl} > (Z+1)/Z. \tag{4.150}$$

The ratio $Z_{nl}^+/Z_{nl} > 1$ implies a contraction of the electronic orbitals of the ion relative to that of the atom (in the same electron configuration). Recalling Eq. (2.49b) the inequalities 4.150 suggest that the contraction increases *progressively* (i.e., more than linearly) with growing distance from the nucleus, the largest contraction being expected for the valence orbitals. The emerging physical picture is one in which the valence electron is pulled towards/into the electron core (if present).

To further explore the phenomenology of screening we have a closer look at the singly ionized alkaline-earth ions. For these ions we have $Z_c^+ = 2$, like in hydrogenic helium, He^+. This means that the Rydberg charge has doubled with respect to the neutral atom; i.e., to first approximation the binding energy of the valence electron has to increase by a factor 4. This is confirmed by Fig. 4.13. For comparison the levels of the He^+ ion are included in the figure. Apart from the larger binding energies, the level diagram is quite similar to that of the alkali atoms. For the l dependence this becomes evident by comparing Figs. 4.10*b* and 4.13*b*. The hydrogenic-helium limiting behavior is implicit in Eq. (4.143) because it depends on Z_c^+ (not on Z) : $\delta_{nl} \to 0$ for $l \gg 1$ and $\delta_{nl}/n \to 0$ for $n \gg 1$.

A numerical comparison between atoms and ions (see Table 4.2) shows that in all cases the screening efficiency, as defined by Eq. (4.149), is smaller in the ions. This is in accordance with the physical picture of progressive contraction in which the valence electron is pulled into the core. Closer inspection of Table 4.2 reveals some interesting differences between atoms and ions. For the lowest d levels the quantum defect increases (i.e., the ion is less hydrogenic than the atom) but for the lowest s and p levels the opposite occurs. So, aside from the tendency of pulling the valence electron into the electron core another physical mechanism comes into play. This mechanism has to be substantial because for the heavy ions *calcium* (Ca^+), *strontium* (Sr^+) and *barium* (Ba^+) the energy of the lowest d level drops *below* that of the lowest p level ($Z_{nd}/n_d > Z_{np}/n_p$). For the light ions, *beryllium* (Be$^+$) and *magnesium* (Mg$^+$), this is not the case. As we shall see this points to differences in screening properties between the inner core ($1s^2, 2s^2, 2p^6$) and outer core electrons ($3s^2, 3p^6$, *etc.*) which has the net effect of expelling valence charge away from the nuclear region. We illustrate this phenomenon with a few examples:

- In the case of the *lithium* isoelectronic sequence Li, Be$^+$ and B^{2+} only the $1s^2$ core is present. Table 4.2 reveals that the screening efficiency of the $2s$ valence orbital is modest. It decreases from 87% to 83% while the orbital becomes more hydrogenic when increasing the nuclear charge (δ_{2s} decreases by 50% from 0.411 to 0.203). The preferential binding decreases from $(Z_{ns}/Z_{np})^2 = 1.53$ in Li to 1.19 in B^{2+}. The increase in nuclear charge does not affect the $2p$ orbital which remains close to hydrogenic, also in the ions ($\delta_{2p} \simeq 0.041$). All this is plausible because the radial distribution function of the $1s$ core has little overlap with that of the $2p$ orbital as shown in Fig. 4.12*b*.

- Also for the *sodium* isoelectronic sequence Na, Mg$^+$ and Al^{2+} the outer core is absent. The inner core consists of closed $1s^2$, $2s^2$ and $2p^6$ shells. Table 4.2 shows that the screening efficiency of the $3s$ valence orbital (92% in Na) is better than that of the $2s$ orbital. Not surprisingly, because we have 10 rather than 2 core electrons involved in the screening. However, the $3s$ orbital is clearly less hydrogenic although this improves ionic charge (δ_{3s} decreases by 33% from 1.373 to 0.925). The preferential binding decreases from $(Z_{ns}/Z_{np})^2 = 1.68$ in Na to 1.30 in Al^{2+}. To a lesser extent this trend is also present for the $3p$ orbital (δ_{3p} decreases with 39% from 0.883 to 0.628). The screening of the valence electron in the $3d$ orbital remains close to perfect ($> 99\%$). Although the quantum defect remains small it becomes *less* hydrogenic (δ_{3d} *increases* from 0.01 to 0.05). All this is plausible when comparing the radial distribution function (2.46) for the $2p$ orbital with $Z_c = Z - 4 = 8$ with that of the $3s$, $3p$ and $3d$ orbitals for which $Z_c = 2$. For the $3s$ and $3p$ orbitals the overlap is substantial, for the $3d$ orbital it is small.

- The perfect screening of the $3d$ orbital in Na, Mg$^+$ and Al^{2+} is lost when turning to the *potassium* isoelectronic sequence K, Ca$^+, \cdots$ Cr^{5+}. This has to do with the presence of the *outer* core ($3s^2$ and $3p^6$ shells). The outer core contracts with respect to the inner core because the increase in effective nuclear charge is largest for the outer shells. Increasing Z from 19 in K to 20 in Ca$^+$ the $1s^2$ core contraction is small because $Z^+_{1s}/Z_{1s} \simeq 1.05$. Also for the $2s^2$ and $2p$ the core contraction is small: $Z^+_{2s}/Z_{2s} \simeq 1.06$ and $Z^+_{2p}/Z_{2p} \simeq 1.07$. These estimates are made for maximal screening by the inner-lying shells: $Z^+_{nl}/Z_{nl} = (Z - \sigma_{nl} + 1)/(Z - \sigma_{nl})$ with $\sigma_{1s} = 0$, $\sigma_{2s} = 2$ and $\sigma_{2p} = 4$. For the *outer* core electrons the core contraction is larger, $Z^+_{3s}/Z_{3s} \simeq 1.11$ ($\sigma_{3p} = 10$) and $Z^+_{3p}/Z_{3p} \simeq 1.14$ ($\sigma_{3p} = 12$). Table 4.2 shows that the $4s$ valence orbital becomes more hydrogenic (δ_{4s} decreases by 1.032). To a lesser extent this is also the case for the $4p$ orbital (δ_{4p} decreases by 0.786). As the $3d$ orbital has much less overlap with the core electrons the increase in Z_c leads to a *reduction* in screening, the orbital becoming less hydrogenic (δ_{3d} *increases* by 0.528). Hence, the binding of the $3d$ electron grows relative to that of the $4s$ and $4p$ electrons. Further increasing Z_c by turning to doubly ionized *scandium* (Sc^{2+}) the $3d$ orbital contracts even further and its energy even drops below that of the $4s$ level, thus restoring the hydrogenic ordering of the levels. The contraction of the $3d$ orbital with growing nuclear charge is sometimes referred to as the *collapse of the* $3d$ *shell*. We return to this feature in Chapter 10.

In summary: we identified two opposing mechanisms which affect the screening of the valence electron. The increase in Z pulls the valence electron towards the nucleus, which *always* results in increased binding (Z_c doubles). In the presence of an outer core, the valence electron is pulled into the core electron cloud which further *increases* the binding by a *decrease* of screening. On the other hand, the same increase in Z results in a contraction of the electron core. This *decreases* the binding of those valence electrons that penetrate deeply into the core, the valence electrons in s orbitals and (to a lesser extent) p orbitals.

Table 4.3: Fine structure splitting of hydrogen and alkali atoms. The hydrogen and deuterium data are taken from [61]; those of lithium from [24, 97]; the rest of the table is based on the NIST Atomic Spectra Database Levels Data [66].

$\mathrm{D}_1 : n\,^2P_{1/2} - n\,^2S_{1/2}$; $\mathrm{D}_2 : n\,^2P_{3/2} - n\,^2S_{1/2}$; $\Delta W_{3/2} = E(n\,^2P_{3/2}) - E(n\,^2P_{1/2})$

Problem 4.9. Consider a hydrogen-like isoelectronic pair of an atom and a singly charged ion in states with the same quantum numbers n and l. Show that the screening efficiency of the valence electron in atom and ion are equal if the following condition is satisfied:

$$\delta_{nl}^{+} = \tfrac{1}{2}\delta_{nl}\frac{1-\delta_{nl}^{+}/n}{1-\delta_{nl}/n},$$

where δ_{nl} and δ_{nl}^{+} are the quantum defects of the atom and ion, respectively, and $\delta_{nl}/n \ll 1$. The relation shows that in a general comparison between two isoelectronic states with equal n and l, a smaller quantum defect is not always equivalent with better screening.

Solution. For $\delta_{nl}/n \ll 1$ the screening efficiency is given by Eq. (4.149). For the atom the nuclear charge number is Z and the Rydberg charge number $Z_c = 1$; for the isoelectronic singly charge ion these quantities increase by one, $Z^{+1} = Z + 1$ and $Z_c^{+} = Z_c + 1$. Substituting this into Eq. (4.149) for atom and ion we find for equal screening:

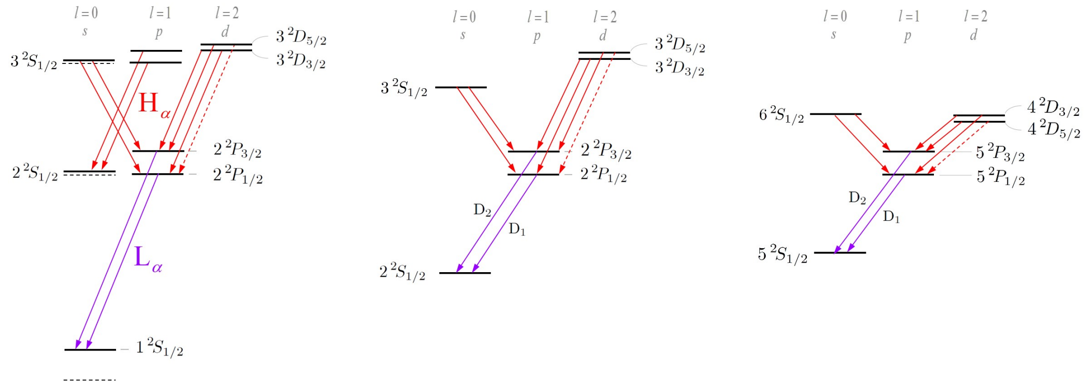
$$\hat{\sigma}_{nl}^{+} = 1 - \frac{Z_c^{+}}{Z^{+} - Z_c^{+}}\frac{\delta_{nl}^{+}/n}{1-\delta_{nl}^{+}/n} = 1 - \frac{Z_c + 1}{Z - Z_c}\frac{\delta_{nl}^{+}/n}{1-\delta_{nl}^{+}/n} = 1 - \frac{Z_c}{Z - Z_c}\frac{\delta_{nl}/n}{1-\delta_{nl}/n} = \hat{\sigma}_{nl}.$$

Since $Z_c = 1$ we have $Z_c + 1 = 2Z_c$ and this leads to the desired condition. □

4.6.3 Screening by core electrons - effect on fine structure

An alternative view on screening can be obtained by analyzing the influence of core electrons on the magnitude of the spin-orbit splitting. To introduce this alternative we present in Table 4.3 the spin-orbit splitting of the (lowest-n) ^2P term, $\Delta W_{3/2}$, as observed in the alkali atoms, together with the Lyman α splitting in *hydrogen* (H) and *deuterium* (D). This ^2P splitting is usually referred to as the *doublet splitting* in hydrogen-like atoms. Included in the table are further the binding energies of the (lowest-n) ^2S and ^2P levels (represented by their effective principal quantum number as well as in Ry atomic units) along with the corresponding wavelength of the optical transitions to the $^2S_{1/2}$ ground states. For the alkalies these transitions are referred to as the D_1 and D_2 lines, respectively (see Fig. 4.14). The D_1, D_2 doublet shows up as a characteristic feature in the optical window of the alkali spectra.

Note that the magnitude of the doublet splitting grows by orders of magnitude when the atomic number increases from $Z = 1$ in *hydrogen* to $Z = 87$ in *francium* (Fr) but in all cases this splitting



hydrogen *lithium* *rubidium*

Figure 4.14: Fine structure and electric-dipole transitions in hydrogen-like atoms. *Left:* Lyman-α and Balmer-α transitions in atomic hydrogen; *Middle and Right*: The D_1, D_2 doublet structure observed in the spectra of alkali atoms is closely related to the rotational structure of the Lyman-α doublet in hydrogen. The fine structure of the $^2D_{3/2,5/2}$ levels is regular (hydrogen-like) in *lithium* but anomalous (inverted) in *rubidium.* Such anomalies arise from kinematic correlations between the electrons (see Chapter 8) but do not affect the selection rules.

remains much smaller than the $n\,^2S - n\,^2P$ splitting (which is roughly 2 eV - see Fig. 4.9). The increase of the doublet splitting with Z may be large in absolute terms, it does not match the enormous increase predicted by the Z^4 scaling of the hydrogenic formula (4.137). As we are aware of the screening by core electrons this does not come as a surprise. Heuristically, the core electrons reduce the effective nuclear charge, which leads to a reduction of the velocity-induced magnetic field and the spin-orbit coupling accordingly. An impression of the influence of screening on the spin-orbit interaction can be obtained using a semi-empirical expression discovered by Landé [70]. This expression follows by substituting the observed binding energies, as given by Eq. (4.143), into Eq. (4.137) for the doublet splitting,

$$\Delta W_{l+1/2} = \alpha^2 \frac{Z_c^2 Z_i^2}{2\bar{n}_l^{*3} l(l+1)} \text{ Hartree.} \tag{4.151}$$

Here Z_c is the Rydberg charge, Z_i the *internal charge* and $\bar{n}_l^*$ is the doublet-averaged effective principal quantum number of the ^2P doublet. In hydrogen $Z_i = Z$ and $\bar{n}_l^* = n$. For the ^2P doublets in the alkalies, Z_i can be calculated with Eq. (4.151) using the experimental values for l, n_l^* and $\Delta W_{l+1/2}$; the results are listed in Table 4.3. Note that $(Z - Z_i)$ increases only modestly from ~ 2 in Li to ~ 6 in Cs with Z increasing from 3 to 58. This suggests that only the innermost core electrons are effective in suppressing the spin-orbit field. Roughly speaking, we have $Z_i \simeq Z - 4$ for p electrons. Francium differs because relativistic effects dominate. We return to these issues when discussing many-electron atoms.

Note that the D$_1$ and D$_2$ transition frequencies depend slightly on the isotope under consideration. In Table 4.3 this is demonstrated for the light isotopes, *hydrogen*, *deuterium* and *lithium* (^{6}Li and ^{7}Li). For *sodium* (Na) and the heavier alkalies this *isotope shift* is too small to be visible at the wavelength resolution presented. The origin of the isotope shift is found in two isotope-dependent phenomena that affect the binding energy: (a) the *reduced mass correction*, introduced in Section 2.1; (b) the *nuclear volume correction* to be discussed in Section 6.1. For the hydrogen isotopes the nuclear volumes are small and the reduced mass correction large; i.e., the latter completely dominates the shift (see Problem 4.10). For the lithium isotopes the two corrections come in on equal footing. Knowledge of the mass related corrections are essential for the determination of the Lamb shift, crucial for precision tests of quantum electrodynamics. Note that, aside from the isotope effect on the binding energy of the $^2P_{1/2}$ and $^2P_{3/2}$ levels, there is also a small isotope effect of the doublet splitting itself. The latter has to be small because the mentioned corrections are predominantly common to the ${}^2P_{1/2}$ and ${}^2P_{3/2}$ levels. It is a challenge for theoreticians and experimentalists alike to attain the required precision for a consistent determination of the isotope effects on the D_1 and D_2 lines as well as that on the spin-orbit splitting [97].

Problem 4.10. The Lyman-α isotope shift between hydrogen and deuterium is $\Delta\lambda = 0.033$ nm (see Table 4.3). Show that this shift is (mostly) explained by the reduced mass correction.

Solution. Using the Rydberg formula (2.35) we find that the Lyman-α wavelength ratio is inversely proportional to the ratio of Rydberg constants

$$\frac{\lambda_H}{\lambda_D} = \frac{R_D}{R_H} = \frac{1 + m_e/m_p}{1 + m_e/m_d} \simeq 1.000272,$$

where $m_p = 1.007276466812$ amu is the proton mass and $m_d = 2.013553212712$ amu the deuteron mass. Hence, we calculate λ_H to be 0.0272% larger than that of deuterium, which corresponds to a reduced mass correction of 0.033057 nm and explains the observed isotope shift. □

4.6.4 Transition dipole moments in the presence of spin-orbit coupling

In the presence of spin-orbit coupling the m_l is no longer a good quantum number and this has consequences for the calculation of the transition-dipole elements of the electric-dipole operator. In this case the states are written as $|nlsjm_j\rangle$ and the transition dipole is of the form

$$\mathbf{D}_{eg} = D_{eg}\hat{\mathbf{u}}_q^* \tag{4.152}$$

where $e = |n'l's'j'm'\rangle$, $g = |nlsjm\rangle$ and

$$D_{eg} = -ea\,\langle n'l's'j'm'|\,\sqrt{4\pi/3}\rho Y_1^q(\hat{\mathbf{r}})\,|nlsjm\rangle \tag{4.153}$$

is the *transition dipole moment*, with $q = m' - m$. In this case we immediately turn to the canonical approach. Because the operators $\sqrt{4\pi/3}\,erY_1^q(\hat{\mathbf{r}})$ are irreducible vector operators we can apply the Wigner-Eckart theorem (K.24) and obtain

$$D_{eg} = -ea(-1)^{j'-m'}\langle n'l's'j'||\sqrt{4\pi/3}\rho Y_1(\hat{\mathbf{r}})||nlsj\rangle \begin{pmatrix} j' & 1 & j \\ -m' & q & m \end{pmatrix}. \tag{4.154}$$

In this case the reduced matrix element can be further reduced to the standard representation $\{\mathbf{L}^2, L_z, \mathbf{S}^2, S_z\}$. For this we use the repeated reduction formula (K.62),

$$\langle n'l's'j'||\sqrt{4\pi/3}\rho Y_1(\hat{\mathbf{r}})||nlsj\rangle = (-1)^{j+l'+s+1}\delta_{s,s'} \\ \times \langle n'l'||\sqrt{4\pi/3}\rho Y_1(\hat{\mathbf{r}})||nl\rangle\sqrt{(2j+1)(2j'+1)} \begin{Bmatrix} l' & j' & s \\ j & l & 1 \end{Bmatrix}. \tag{4.155}$$

Substituting Eq. (2.79) this becomes

$$\langle n'l's'j'||\sqrt{4\pi/3}\rho Y_1(\hat{\mathbf{r}})||nlsj\rangle = (-1)^{j+s+1+\max(l,l')}\delta_{s,s'}\delta_{l',l\pm1}\mathcal{R}_{n'l',nl}\times \\ \times \sqrt{\max(l,l')}\sqrt{(2j+1)(2j'+1)} \begin{Bmatrix} l' & j' & s \\ j & l & 1 \end{Bmatrix}. \tag{4.156}$$

Writing the transition dipole moment in the form

$$D_{n'l's'j'm'\leftrightarrow nlsjm} = -ea\mathcal{R}_{n'l',nl}\mathcal{A}_{j'm'jm}^{l'ls}\delta_{s,s'}\delta_{l',l\pm1}, \tag{4.157}$$

we find for the angular contribution (after reordering the $3j$ symbol)

$$\mathcal{A}^{l'ls}_{j'm'jm} = (-1)^{-m'+s+\max(l,l')}\sqrt{\max(l,l')}\sqrt{(2j+1)(2j'+1)}\begin{Bmatrix} l' & j' & s \\ j & l & 1 \end{Bmatrix}\begin{pmatrix} j & 1 & j' \\ m & q & -m' \end{pmatrix}. \tag{4.158}$$

The *selection rules* for fine-structure transitions (determined by the $3j$ symbol) are:

$$\Delta m = 0, \pm 1 \qquad \text{for } \pi, \sigma^{\pm} - \text{transitions} \tag{4.159a}$$

$$\Delta j = 0, \pm 1 \qquad (\text{excluding } \; j = 0 \leftrightarrow j' = 0). \tag{4.159b}$$

These selection rules come on top of the *electric-dipole parity selection rule* (2.73),

$$\Delta l = \pm 1 \qquad \Delta s = 0\,. \tag{4.160}$$

In addition also the triangular inequalities $\Delta(l, s, j)$ and $\Delta(l'sj')$ must be satisfied. Note that the case $j = j' = 0$ is excluded because the triangular inequality $\Delta(j, j', 1)$ cannot be satisfied. The rule $\Delta s = 0$ is trivial because in one-electron atoms the total spin is $s = \frac{1}{2}$, which is the intrinsic spin of the electron and cannot change. The allowed electric-dipole transitions between lower levels of hydrogen-like atoms are sketched in Fig. 4.14.

4.6.4.1 Example: sp transitions in hydrogen-like atoms ($s = 1/2$)

The result for the angular matrix elements of $p \to s$ transitions in the presence of fine-structure coupling $\left(j' = \frac{1}{2}, \frac{3}{2} \to j = \frac{1}{2}\right)$ depends, for given j', on $m' \equiv m_{j'}$,

$$\mathcal{A}^{l'ls}_{\frac{3}{2}m',\frac{1}{2}\pm\frac{1}{2}} = (-)^{\frac{3}{2}-m'}\sqrt{8}\begin{Bmatrix} 1 & \frac{3}{2} & \frac{1}{2} \\ \frac{1}{2} & 0 & 1 \end{Bmatrix}\begin{pmatrix} \frac{1}{2} & 1 & \frac{3}{2} \\ \pm\frac{1}{2} & m' \mp \frac{1}{2} & -m' \end{pmatrix} = (-)^{\frac{3}{2}-m'}\tfrac{1}{3}\sqrt{\tfrac{3}{2} \pm m'}, \tag{4.161a}$$

$$\mathcal{A}^{l'ls}_{\frac{1}{2}m',\frac{1}{2}\pm\frac{1}{2}} = (-)^{\frac{3}{2}-m'}\sqrt{8}\begin{Bmatrix} 1 & \frac{1}{2} & \frac{1}{2} \\ \frac{1}{2} & 0 & 1 \end{Bmatrix}\begin{pmatrix} \frac{1}{2} & 1 & \frac{1}{2} \\ \pm\frac{1}{2} & m' \mp \frac{1}{2} & -m' \end{pmatrix} = (-)^{\frac{3}{2}-3m'}\tfrac{1}{3}\sqrt{\tfrac{3}{2} \mp m'}. \tag{4.161b}$$

Summing over the magnetic quantum numbers of the $j = \frac{1}{2}$ level (which is the only s level) we obtain

$$\sum_{m=-1/2}^{1/2} \mathcal{A}^2_{j'm',\frac{1}{2}m} = \tfrac{1}{3}. \tag{4.162}$$

Note that (for given $l', l,$ and s) this sum is *independent* of j' and m'; i.e., the sum is same for all values of the magnetic quantum number of the p level. This is illustrated in Fig. 4.15. This sum rule can be understood from the physical point of view when considering electric-dipole transitions. Since the electric-dipole operator does not couple to the spin (it acts in a different sector of Hilbert space), the spin cannot affect the total electric dipole transition rate. It only distributes the rate over the available final states in the form of σ_+, σ_- and π contributions.

4.7 Fine structure in an applied magnetic field

4.7.1 Introduction

In the presence of an externally applied magnetic field $\mathbf{B}$ the vector potential is nonzero, $\mathbf{A} = \frac{1}{2}\mathbf{B}\times\mathbf{r}$ (presuming the field to be homogeneous across the atom), and using the results of Sections 4.2 and 4.3, the Hamiltonian for the magnetic fine structure (4.120) can be written in the form of an *effective* Hamiltonian valid to first order in perturbation theory for given values of n and l - compare with Eq. (4.124)

$$\mathcal{H} = \mathcal{H}_0 + \mathcal{H}_r + (\zeta_{nl}/\hbar^2)\mathbf{L}\cdot\mathbf{S} - (\boldsymbol{\mu}_s + \boldsymbol{\mu}_L)\cdot\mathbf{B}. \tag{4.163}$$

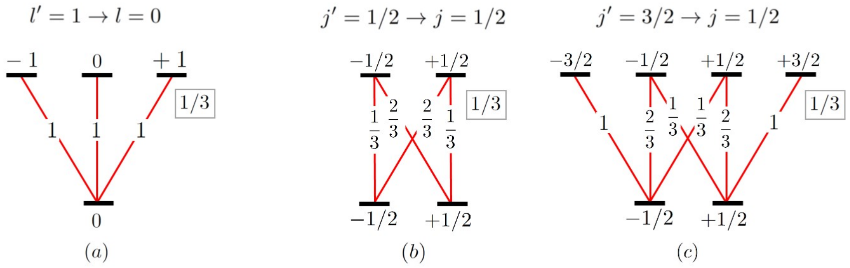


Figure 4.15: The angular contributions to the transition strength between two angular momentum levels (l' and l) is independent of the presence (or absence) of fine structure. This is illustrated for $p \to s$ transitions in hydrogen-like atoms with fine structure: (a) in principal structure (see also Fig. 2.4); (b) from $j' = \frac{1}{2}$ level; (c) from $j' = \frac{3}{2}$ level. Note that the sum of the probabilities starting from any of the $m_{j'}$ levels, always yields the *same* value (normalized to unity, not counting a common prefactor - here 1/3 in all three cases).

Here $\mathcal{H}_0$ is the Schrödinger Hamiltonian (2.1) and $\mathcal{H}_r$ is the relativistic correction given by Eq. (4.23). Substituting Eqs. (4.53) and (4.80) for the magnetic moments the Hamiltonian takes the form

$$\mathcal{H} = \mathcal{H}_0 + \mathcal{H}_r + (\zeta_{nl}/\hbar^2)\mathbf{L}\cdot\mathbf{S} + (g_L\mu_B\mathbf{L} + g_e\mu_B\mathbf{S})\cdot\mathbf{B}/\hbar. \tag{4.164}$$

We write this as $\mathcal{H} = \mathcal{H}_0 + \mathcal{H}_r + \mathcal{H}'$, where

$$\mathcal{H}' = \mathcal{H}_{LS} + \mathcal{H}_Z \tag{4.165}$$

is the perturbation to be considered, with

$$\mathcal{H}_{LS} = (\zeta_{nl}/\hbar^2)\mathbf{L}\cdot\mathbf{S} \quad \text{and} \quad \mathcal{H}_Z = (g_L\mu_B L_z + g_e\mu_B S_z)B/\hbar. \tag{4.166}$$

representing the spin orbit coupling and the orbital and Zeeman terms, respectively, with the quantization axis (z axis) chosen along the magnetic field direction.

We calculate the splitting of a fine-structure level of given n and l using first-order perturbation theory for a degenerate level. Unlike the zero-field case, for finite fields the perturbation theory does not reduce to ordinary first-order perturbation theory. Although $\mathbf{L}\cdot\mathbf{S}$ and $\mathcal{H}_Z$ commute *separately* with $\mathcal{H}_0 + \mathcal{H}_r$, they do *not* commute *mutually* (see Problem 4.7). Therefore, the operators do not share a basis. Physically, there is competition between the mutual coupling between $\mathbf{L}$ and $\mathbf{S}$ and the coupling of $\mathbf{L}$ and $\mathbf{S}$ individually with the external $\mathbf{B}$ field. In low fields the $\mathbf{L}\cdot\mathbf{S}$ coupling is dominant, whereas in high fields it is replaced by the $\mathbf{L}\cdot\mathbf{B}$ and $\mathbf{S}\cdot\mathbf{B}$ couplings. This crossover from low-field to high-field behavior is known as the *Paschen-Back effect* [78]. In intermediate fields the Hamiltonian is neither diagonal in the $\{|nlsjm_j\rangle\}$ (*coupled*) representation nor in the $\{|nlm_lsm_s\rangle\}$ (*uncoupled*) representation and to calculate the level shifts to first order we have to diagonalize the perturbation matrix. This is equivalent to solving the secular equation (I.24),

$$|\mathcal{H}'_{i,j} - \varepsilon\delta_{i,j}| = 0, \tag{4.167}$$

where $\mathcal{H}'_{i,j}$ are the matrix elements of the perturbation $\mathcal{H}'$ in the representation of choice.

Also for *many-electron atoms,* with total orbital angular momentum L and total spin S, the above diagonalization procedure can be used to describe the fine structure. This is the case if the perturbation can be written in the form (4.165) and is known as LS coupling or *Russell-Saunders coupling* (cf. Section 10.6.4)

4.7.2 Matrix element in the uncoupled basis

To solve the secular equation in the *uncoupled* representation we use the inner product rule (3.159b) to write the perturbation in the form

$$\mathcal{H}' = (\zeta_{nl}/\hbar^2)\left[L_zS_z + \tfrac{1}{2}(L_+S_- + L_-S_+)\right] + (g_L\mu_B L_z + g_e\mu_B S_z)B/\hbar. \tag{4.168}$$

Note that this Hamiltonian conserves the total angular momentum along the z axis; i.e., $m_l + m_s$ is a good quantum number (J_z commutes with the Hamiltonian) for all values of the magnetic field. This quantum number will be denoted by m_j. The diagonal matrix elements of the perturbation $\mathcal{H}'$ in the uncoupled basis $\{|nlm_l sm_s\rangle\}$ and for given values of $m_j = m_l + m_s$ are given by

$$\begin{aligned}\langle nlm_l sm_s|\mathcal{H}'|nlm_l sm_s\rangle &= \langle nl(m_j - m_s)sm_s|\mathcal{H}'|nl(m_j - m_s)sm_s\rangle \\ &= \zeta_{nl}(m_j - m_s)m_s + [g_L m_j + (g_e - g_L)m_s]\,\mu_B B \\ &\equiv \langle m_j m_s|\mathcal{H}'|m_j m_s\rangle \equiv \mathcal{H}'_{m_j m_s m_s},\end{aligned} \tag{4.169}$$

with ζ_{nl} the spin-orbit coupling constant. Note that in these matrix elements the states $\{|nlm_l sm_s\rangle\}$ share fixed values for the quantum numbers n, l and s; only the values of m_l and m_s vary. Using the relation $m_l = m_j - m_s$ we gave preference to specification of m_j and m_s rather than m_l and m_s. Turning to the shorthand notation $|nlm_l sm_s\rangle \to |m_j m_s\rangle$ the matrix elements take the form $\langle m_j m_s'|\mathcal{H}'|m_j m_s\rangle$. Since m_j is conserved by $\mathcal{H}'$ the notation can be condensed to $\mathcal{H}'_{m_j m_s' m_s}$. The terms $\frac{1}{2}(\zeta_{nl}/\hbar^2)\,(L_+S_- + L_-S_+)$ give rise to off-diagonal elements and are calculated using the shift operators (1.59) and the conservation of m_j,

$$\begin{aligned}\langle nlm_l' sm_s'|\mathcal{H}'|nlm_l sm_s\rangle &= \langle nl(m_j - m_s \pm 1)s(m_s \mp 1)|\mathcal{H}'|nl(m_j - m_s)sm_s\rangle \\ &= \tfrac{1}{2}\zeta_{nl}\sqrt{l(l+1) - (m_j - m_s)(m_j - m_s \pm 1)}\sqrt{s(s+1) - m_s(m_s \mp 1)} \\ &\equiv \mathcal{H}'_{m_j(m_s \mp 1)m_s}.\end{aligned} \tag{4.170}$$

Hence, the perturbation couples states differing in m_s such that $\Delta m_s = \pm 1$ while $m_l + m_s = m_j$ remains conserved. For the coupled basis $\{|nlsjm_j\rangle\}$ this implies that the perturbation couples states differing in j such that $\Delta j = \pm 1$ while m_j remains conserved. In the description of the field dependence preference will be given to expressing coupled states in terms of uncoupled states, rather than the other way around, because in the uncoupled representation the expressions for the limiting cases of low and high field remain intuitively transparent. In the coupled representation the latter is only the case for the low-field limit.

4.7.3 Diagonalization of the perturbation matrix for hydrogen-like atoms

For hydrogen-like atoms the solution of the secular equation (4.167) can be obtained analytically for arbitrary magnetic fields because the electronic states are *electron spin doublets* $\left(s = \frac{1}{2}\right)$. As shown in Section 4.5 the spin-orbit shifts in zero field can be expressed as

$$\Delta E_{n,j}^{LS} = \begin{cases} +\frac{1}{2}\zeta_{nl}l & \left(j = l + \frac{1}{2}\right) \\ -\frac{1}{2}\zeta_{nl}(l+1) & \left(j = l - \frac{1}{2}\right) \end{cases} \quad \text{for } l \neq 0, \tag{4.171}$$

where the manifold with the highest (lowest) multiplicity has the highest (lowest) energy. In the absence of orbital angular momentum ($l = 0$) this shift is absent. For $l > 0$ the perturbation matrix takes the form

$$\mathcal{H}' = \begin{pmatrix} \mathcal{H}'_{M\uparrow\uparrow} & 0 & 0 & \cdots & 0 & 0 & 0 \\ 0 & \mathcal{H}'_{(M-1)\uparrow\uparrow} & \mathcal{H}'_{(M-1)\uparrow\downarrow} & \cdots & 0 & 0 & 0 \\ 0 & \mathcal{H}'_{(M-1)\downarrow\uparrow} & \mathcal{H}'_{(M-1)\downarrow\downarrow} & \cdots & 0 & 0 & 0 \\ \vdots & \vdots & \vdots & & \vdots & \vdots & \vdots \\ 0 & 0 & 0 & \cdots & \mathcal{H}'_{(-M+1)\uparrow\uparrow} & \mathcal{H}'_{(-M+1)\uparrow\downarrow} & 0 \\ 0 & 0 & 0 & \cdots & \mathcal{H}'_{(-M+1)\downarrow\uparrow} & \mathcal{H}'_{(-M+1)\downarrow\downarrow} & 0 \\ 0 & 0 & 0 & \cdots & 0 & 0 & \mathcal{H}'_{-M\downarrow\downarrow} \end{pmatrix}, \tag{4.172}$$

where $M \equiv l + \frac{1}{2}$ and ↑ is the usual short hand notation for $m_s = \frac{1}{2}$ (and ↓ for $m_s = -\frac{1}{2}$). The quantum number m_j varies within the range $-M \leq m_j \leq M$. Note that the matrix is a $d \times d$ matrix, where $d = (2l+1)(2s+1)$ is the dimension of the angular momentum subspace in which **L** and **S** operate. The characteristic equation is of the asymmetric type (cf. Appendix H.3) and factorizes into a product of two determinants of size (1×1) and $2l$ determinants of size (2×2), each characterized by its own value of $m_j = m_l + m_s$, with $-M \leq m_j \leq M$. With the aid of Eqs. (4.169) and (4.170) the matrix elements are found to be

$$\mathcal{H}'_{m_j\uparrow\uparrow} = +\tfrac{1}{2}\zeta_{nl}\left(m_j - \tfrac{1}{2}\right) + g_L\mu_B m_j B + \tfrac{1}{2}\mu'_B B \tag{4.173a}$$

$$\mathcal{H}'_{m_j\downarrow\downarrow} = -\tfrac{1}{2}\zeta_{nl}\left(m_j + \tfrac{1}{2}\right) + g_L\mu_B m_j B - \tfrac{1}{2}\mu'_B B \tag{4.173b}$$

$$\mathcal{H}'_{m_j\downarrow\uparrow} = +\tfrac{1}{2}\zeta_{nl}(l + \tfrac{1}{2})(1 - \tilde{m}_j^2)^{1/2} = \mathcal{H}'_{m_j\uparrow\downarrow}, \tag{4.173c}$$

where

$$\mu'_B \equiv (g_e - g_L)\,\mu_B \simeq \mu_B \tag{4.174a}$$

$$\tilde{m}_j \equiv m_j/(l + \tfrac{1}{2}) \quad \text{with} \quad -1 \leq \tilde{m}_j \leq 1. \tag{4.174b}$$

4.7.3.1 Pure states

Note that for $m_j = \pm(l + \frac{1}{2})$, the coupling term vanishes, $\mathcal{H}'_{m_j\downarrow\uparrow} = 0$. Therefore, the corresponding states are called *pure states*. They are also known under the name *stretched states* because the orbital and spin angular momentum spins are coupled "parallel" and have maximum projection along the quantization axis,

$$|j_{\max}, \pm(l + \tfrac{1}{2})\rangle = \left|l, \pm l; s, \pm\tfrac{1}{2}\right\rangle. \tag{4.175}$$

The corresponding energies are

$$\varepsilon_\pm = \tfrac{1}{2}\zeta_{nl} l \pm (\mu_L + \mu_e)\,B \quad \text{for} \quad m_j = \pm(l + \tfrac{1}{2}). \tag{4.176}$$

Here $\mu_L \equiv g_L\mu_B l$ and $\mu_e \equiv g_e\mu_B s$ are, respectively, the *orbital* and *intrinsic* magnetic moment of the electron (cf. Sections 4.3.3 and 4.3.5).

4.7.3.2 Mixed states

The other states, $m_j \neq \pm(l + \frac{1}{2})$, are called *mixed states* because they involve linear combinations of the uncoupled basis states,

$$|j_{\max}, m_j\rangle = +\cos\alpha|l, \left(m_j - \tfrac{1}{2}\right); s, \uparrow) + \sin\alpha|l, \left(m_j + \tfrac{1}{2}\right); s, \downarrow) \tag{4.177a}$$

$$|j_{\min}, m_j\rangle = -\sin\alpha|l, \left(m_j - \tfrac{1}{2}\right); s, \uparrow) + \cos\alpha|l, \left(m_j + \tfrac{1}{2}\right); s, \downarrow). \tag{4.177b}$$

With this choice of coefficients the states $|j_{\max}, m_j\rangle$ and $|j_{\min}, m_j\rangle$ form an orthonormal pair. The states labeled $j_{\max}$ ($j_{\min}$) are taken to be part of the manifold with highest (lowest) multiplicity. In the limit $B \to 0$ the Zeeman energy vanishes and j becomes a good quantum number, $j_{\max} \to j = l + \frac{1}{2}$ and $j_{\min} \to j = l - \frac{1}{2}$. In this limit the Eqs. (4.177) take the form of the Clebsch-Gordan decomposition (J.45), where the phase factors satisfy the *Clebsch-Gordan phase convention* introduced in Section 4.4.1. We have chosen the phase factors *also for non-zero fields* in accordance with this convention. Because Eq. (4.177a) corresponds in the limit $B \to 0$ to a state of maximal j (parallel coupling) the phase factors are unity. The energies of the mixed states are given by solutions of the secular equation for given value of m_j,

$$W_\pm(m_j) = \tfrac{1}{2}\left(\mathcal{H}'_{m_j\uparrow\uparrow} + \mathcal{H}'_{m_j\downarrow\downarrow}\right) \pm \tfrac{1}{2}\sqrt{(\mathcal{H}'_{m_j\uparrow\uparrow} - \mathcal{H}'_{m_j\downarrow\downarrow})^2 + 4|\mathcal{H}'_{m_j\downarrow\uparrow}|^2}. \tag{4.178}$$

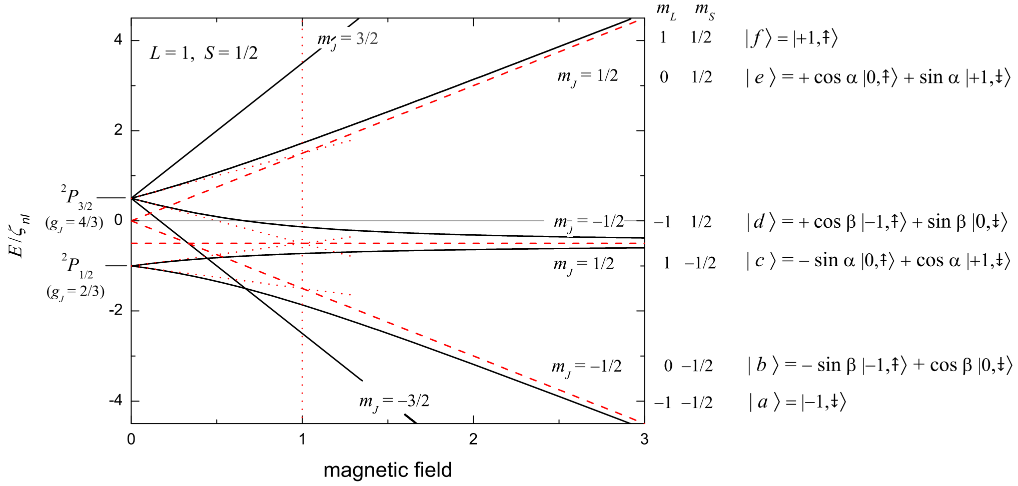

Figure 4.16: Fine structure diagram for the $^2P_{3/2}$ and $^2P_{1/2}$ electronic states and magnetic energy of the various magnetic sublevels from zero field to the Paschen-Back regime as calculated with Eqs. (4.179). The magnetic energy is given in units of the spin-orbit coupling constant ζ_{nl} and the magnetic field in units of the fine-structure crossover field, $|B_{\rm fs}|$. The dashed lines correspond to the high-field approximations - see Eq. (4.190). The dotted lines correspond to the low-field approximation - see Eq. (4.199). The states of equal m_J are LS coupled. The limiting behavior is: (a) $B \to \infty$: $\sin\alpha$, $\sin\beta \to 0$; (b) $B \to 0$: $\cos^2\alpha \to 2/3$, $\cos^2\beta \to 1/3$.

This equation can be written in the form of the *Breit-Rabi formula*,[1]

$$\varepsilon_\pm(m_j) = g_L\mu_B m_j B - \tfrac{1}{4}\zeta_{nl} \pm \tfrac{1}{2}\zeta_{nl}(l+\tfrac{1}{2})\sqrt{1 + 2\tilde{m}_j B/B_{\rm fs} + (B/B_{\rm fs})^2}. \tag{4.179}$$

The characteristic magnetic field,

$$B_{\rm fs} \equiv \zeta_{nl}(l+\tfrac{1}{2})/\mu_B', \tag{4.180}$$

with μ_B' defined by Eq. (4.174a), is called the *fine-structure field*. It represents an *effective internal magnetic field* (as if the external field cannot be completely switched off) and is a measure for the spin-orbit splitting in magnetic field units. Its absolute value,[2] $|B_{\rm fs}|$, is the *fine-structure crossover* field - the intersection point of the low-field and high-field asymptotes of the magnetic field dependence of the energy levels. For the $2p$ level of atomic hydrogen $B_{\rm fs} \simeq 0.8$ T (see Problem 4.11). With Eq. (4.179) we have obtained an expression for the magnetic field dependence of the spin-orbit shift of atomic states with given values of l and $m_j = m_l + m_s \neq \pm(l+\frac{1}{2})$. It describes the crossover from zero field to the high magnetic field limit. In Fig. 4.16 this is illustrated for $^2P_{3/2}$ and $^2P_{1/2}$ atomic states with the magnetic field given in units of the crossover field $|B_{\rm fs}|$.

To obtain the eigenstates corresponding to the energies ε_+ and ε_- we have to determine the coefficients in Eqs. (4.177). This is done by the procedure described in Appendix H.3. For hydrogen-like atoms ($\zeta_{nl} > 0$) we have $\varepsilon_+ > \varepsilon_-$; i.e., ε_+ (ε_-) corresponds to the upper (lower) branch of the doublet. From the limit $B \to 0$ analyzed in Section 4.5 we know that ε_+ corresponds to $|j_{\max}, m_j\rangle$ and ε_- to $|j_{\min}, m_j\rangle$. The amplitudes of the coefficients, $A_+ \equiv \cos\alpha$ and $A_- \equiv \sin\alpha$, follow by substitution of the matrix elements (4.173a)-(4.173c) into Eq. (G.51)

$$A_\pm^2 = \frac{1-\tilde{m}_j^2}{\left(\tilde{m}_j + B/B_{\rm fs} \mp \sqrt{1+2\tilde{m}_j B/B_{\rm fs} + (B/B_{\rm fs})^2}\,\right)^2 + 1 - \tilde{m}_j^2}. \tag{4.181}$$

---

[1] The name refers to the work of Breit and Rabi in relation to the hyperfine structure of atomic hydrogen [22].

[2] Note that $B_{\rm fs}$ can become negative in many-electron atoms (see Section 10.6.5).

High-field limit ($B \gg |B_{\mathrm{fs}}|$)**:** In high magnetic fields we can expand the Breit-Rabi formula (4.179) in powers of B_{fs}/B. Retaining only the terms up to first order in B_{fs}/B we obtain

$$\varepsilon_{\pm}(m_j) = g_L \mu_B m_j B - \tfrac{1}{4}\zeta_{nl} \pm \tfrac{1}{2}\mu_B' B(1 + \tilde{m}_j B_{\mathrm{fs}}/B). \tag{4.182}$$

The leading terms of this expression corresponds to the *high-field asymptotes* indicated by the dashed lines in Fig. 4.16. Using a similar expansion Eq. (4.181) takes the form

$$A_-^2 = \sin^2\alpha \simeq \tfrac{1}{4}(1 - \tilde{m}_j^2)(B_{\mathrm{fs}}/B)^2 \to 0. \tag{4.183}$$

This is an example of *weak coupling (strong asymmetry)* as defined in Appendix G.3.4.

Low-field limit ($B \ll |B_{\mathrm{fs}}|$)**:** For low magnetic fields we can expand Eq. (4.179) in powers of B/B_{fs}. Retaining only the terms up to second order in B/B_{fs} we obtain

$$\varepsilon_{\pm}(m_j) = g_L \mu_B m_j B - \tfrac{1}{4}\zeta_{nl} \pm \tfrac{1}{2}\zeta_{nl}(l + \tfrac{1}{2})[1 + \tilde{m}_j B/B_{\mathrm{fs}} + \tfrac{1}{2}(1 - \tilde{m}_j^2)(B/B_{\mathrm{fs}})^2 + \cdots]. \tag{4.184}$$

The linear and quadratic contributions are referred to as *linear* and *quadratic* Zeeman effects. The linear terms correspond to the *low-field tangents* indicated by the dotted lines in Fig. 4.16. Expanding Eq. (4.181) to first order in B/B_{fs} we obtain

$$A_{\pm}^2 \simeq \tfrac{1}{2}(1 \pm \tilde{m}_j)\,[1 \pm (1 \mp \tilde{m}_j)B/B_{\mathrm{fs}} + \cdots]\,. \tag{4.185}$$

Note that this is *not* an example of the strong coupling limit (weak asymmetry) as defined in Appendix H.3. This would be the case for $m_j = 0$ but this value does not occur in hydrogen-like atoms.

Crossover field ($B = |B_{\mathrm{fs}}|$)**:** Equating Eqs. (4.182) and (4.184) for the high- and low-field tangents we obtain the following expression for the intersection point,

$$\mu_B' B(1 + \tilde{m}_j B_{\mathrm{fs}}/B) = \zeta_{nl}(l + \tfrac{1}{2})(1 + \tilde{m}_j B/B_{\mathrm{fs}}). \tag{4.186}$$

Solving for B we find for the intersection point $B = |B_{\mathrm{fs}}| = |\zeta_{nl}|(l + \frac{1}{2})/\mu_B'$. This point marks the crossover between the low-field and high-field regions. Note that the crossover field does *not* depend on m_j.

Problem 4.11. Calculate the fine-structure field B_{fs} for the $2p$ level of hydrogen.

Solution. Using Eqs. (4.180), (4.136) and (2.33) we obtain the following expression for the fine-structure field in hydrogenic atoms

$$B_{\mathrm{fs}} \simeq \alpha^2 \frac{Z^4}{n^4} \frac{hcR_M}{\mu_B} \frac{(l + {}^1\!/_2)n}{l(l + {}^1\!/_2)(l + 1)}.$$

For the $2p$ state of hydrogen ($n = 2$, $l = 1$ and $Z = 1$) this implies $\frac{1}{16}\alpha^2 hcR_M/\mu_B \simeq 0.8$ T. □

4.7.4 High-field limit - Paschen-Back effect

For magnetic fields much higher than the fine-structure field ($B \gg |B_{\mathrm{fs}}|$) the spin-orbit coupling is weak as compared to the Zeeman interaction. This causes the Zeeman coupling of **L** and **S** individually to the external field to dominate over the spin-orbit coupling between **L** and **S** - see Fig. 4.17. For increasing magnetic field, this manifests itself as a crossover from spin-orbit coupling of **L** and **S** ($B \ll |B_{\mathrm{fs}}|$) to Zeeman coupling of **L** and **S** individually to the magnetic field ($B \gg |B_{\mathrm{fs}}|$). This crossover is known as the *Paschen-Back effect.* Therefore, in the high-field limit the atomic Hamiltonian

$$\mathcal{H} = (\mathcal{H}_0 + \mathcal{H}_r + \mathcal{H}_Z) + \mathcal{H}_{LS} \tag{4.187}$$

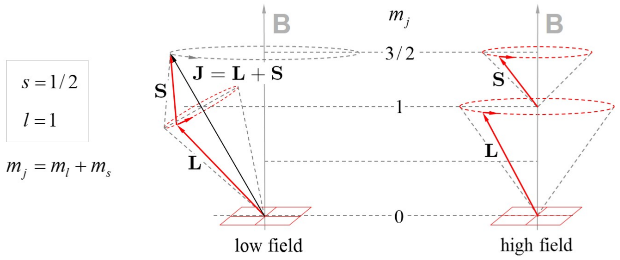

Figure 4.17: Precession of angular momenta in an externally applied magnetic field for the example $l = 1$, $s = \frac{1}{2}$. In *low* fields **L** and **S** are strongly spin-orbit coupled (by $\mathcal{H}_{LS}$) to form the total electronic angular momentum $\mathbf{J} = \mathbf{L}+\mathbf{S}$, which precesses slowly about the field direction as a result of a weak Zeeman coupling, $\mathcal{H}_Z = -\boldsymbol{\mu}_J \cdot \mathbf{B}$; this is most conveniently described in the *coupled* basis $\{|j, m_j\rangle\}$. In *high* fields **L** and **S** are predominantly Zeeman coupled to the external field, $\mathcal{H}_Z = -(\boldsymbol{\mu}_L + \boldsymbol{\mu}_S)\cdot\mathbf{B}$, and precess independently about the field direction; this is best described in the *uncoupled* basis $\{|l, m_l, s, m_s\rangle\}$. Note that $m_j = m_l + m_s$ is a good quantum number in both limits.

is best analyzed in the *uncoupled* representation $\{|nlm_lsm_s\rangle\}$, where $\mathcal{H}_Z$ is diagonal and $\mathcal{H}_{LS}$ acts as the perturbation. In this basis and for given value of n, l, s the perturbation matrix is given by

$$\mathcal{H}^{LS}_{m_l'm_s';m_lm_s} = (\zeta_{nl}/\hbar^2)\langle lm_l'sm_s'|\mathbf{L}\cdot\mathbf{S}|lm_lsm_s\rangle, \tag{4.188}$$

which can be written in the form

$$\mathcal{H}^{LS}_{m_l'm_s';m_lm_s} = (\zeta_{nl}/\hbar^2)\langle lm_l'sm_s'|L_zS_z + \tfrac{1}{2}\left(L_+S_- + L_-S_+\right)|lm_lsm_s\rangle. \tag{4.189}$$

As only the *diagonal matrix elements* of a weak perturbation *contribute to first order* in perturbation theory (see Appendix G.3.4 - weak coupling), in high fields the spin-orbit shift is given by $\Delta E^{LS}_{n;m_lm_s} = \zeta_{nl}m_lm_s$ and the *asymptotic field dependence* (dashed lines in Fig. 4.16) can be expressed as

$$\Delta E_{n;m_lm_s} = \left(g_Lm_l + g_em_s\right)\mu_BB + \zeta_{nl}m_lm_s. \tag{4.190}$$

Note that the derivation of this expression is valid for *arbitrary* values of l and s. Moreover, Eq. (4.190) may be generalized to the case of *many-electron atoms* under conditions of *Russell-Saunders coupling* using the arguments presented in Section 4.7.1 (cf. Section 10.6.4).

4.7.4.1 Hydrogen-like atoms

For hydrogen-like atoms the high-field limit is illustrated in Fig. 4.16 for the case $l = 1$, $s = \frac{1}{2}$, assuming $g_L = 1$ and $g_e = 2$. The stretched cases $m_l = 1$, $m_s = \frac{1}{2}$ and $m_l = -1$, $m_s = -\frac{1}{2}$ correspond to

$$\Delta E_{n;\pm m_l \pm m_s} = \tfrac{1}{2}\zeta_{nl} \pm 2\mu_BB \tag{4.191}$$

and coincide with the straight solid lines in Fig. 4.16. The $m_l = 0$ cases $m_s = \pm\frac{1}{2}$ correspond to

$$\Delta E_{n;\pm m_l \pm m_s} = \pm\mu_BB \tag{4.192}$$

and are represented by the inclined dashed lines in Fig. 4.16. The antiparallel cases $m_l = -1$, $m_s = \frac{1}{2}$ and $m_l = 1$, $m_s = -\frac{1}{2}$ correspond to

$$\Delta E_{n;\pm m_l \pm m_s} = -\tfrac{1}{2}\zeta_{nl} \tag{4.193}$$

and are shown as the horizontal dashed line in Fig. 4.16.

4.7.5 Low-field limit - Landé factor g_J

For magnetic fields much lower than the fine-structure field ($B \ll |B_{\mathrm{fs}}|$) the angular momenta $\mathbf{L}$ and $\mathbf{S}$ are spin-orbit coupled (by $\mathcal{H}_{LS}$) to form the total electronic angular momentum $\mathbf{J} = \mathbf{L} + \mathbf{S}$ (see Fig. 4.17). Under these conditions the atomic Hamiltonian

$$\mathcal{H} = (\mathcal{H}_0 + \mathcal{H}_r + \mathcal{H}_{LS}) + \mathcal{H}_Z \tag{4.194}$$

is best analyzed in the *coupled* representation, $\{|nlsjm_j\rangle\}$, where $\mathbf{L} \cdot \mathbf{S}$ is diagonal and $\mathcal{H}_Z$ acts as the perturbation. In this basis and for given values of n, l, s, j the perturbation matrix is given by

$$\mathcal{H}^Z_{j'm_{j'};jm_j} = \langle j'm_{j'}| g_L L_z + g_e S_z \,|jm_j\rangle \, \mu_B B/\hbar. \tag{4.195}$$

Limiting ourselves to the diagonal terms, we obtain the following expression for the energy shift (Zeeman shift)

$$\Delta E^Z_{j,m_j} = \langle jm_j| g_L L_z + g_e S_z \,|jm_j\rangle \, \mu_B B/\hbar. \tag{4.196}$$

This expression is valid to only first order in perturbation theory because $\mathcal{H}_Z$ is in *not* diagonal in the coupled representation: only the *diagonal matrix elements* of a weak perturbation *contribute to first order* (see Appendix G.3.4 - weak coupling). Interestingly, the operators L_z and S_z cannot change m_l and m_s and, therefore, have to conserve m_j. This is a consequence of the m_j *selection rule* (3.89), $m_j = m_l + m_s$. However, L_z and S_z do *not* conserve j (see Problem 4.12). Only in *low* fields the perturbation can be made sufficiently weak to neglect the off-diagonal terms; i.e., to regard both j and m_j as good quantum numbers of the atomic Hamiltonian (4.194).. Furthermore, using the arguments given in Section 4.7.1, also the analysis of the low-field limit may be generalized to the case of *many-electron atoms* under conditions of *Russell-Saunders coupling* (cf. Section 10.6.4).

Intuitively the situation is also clear: for sufficiently low fields the magnetic moment of the atom will scale with the total electronic angular momentum $\mathbf{J}$,

$$\boldsymbol{\mu}_J \equiv \gamma_J \mathbf{J} \equiv -g_J \mu_B \, (\mathbf{J}/\hbar) \qquad \text{for } B \to 0. \tag{4.197}$$

Note that γ_J and g_J are defined with opposite sign, just as we did for γ_L and γ_e. The value of g_J will turn out to be positive. In terms of $\boldsymbol{\mu}_J$ the Zeeman energy can be described by the effective Hamiltonian

$$\mathcal{H}_Z = -(\boldsymbol{\mu}_L + \boldsymbol{\mu}_s) \cdot \mathbf{B} = -\boldsymbol{\mu}_J \cdot \mathbf{B} \qquad \text{for } B \to 0. \tag{4.198}$$

This Hamiltonian yields a Zeeman shift on top of the zero-field spin-orbit shift ΔE^{LS}_{nj} (for given values of n, l, s, j):

$$\Delta E^Z_{j,m_j} = g_J \mu_B B \langle jm_j|(J_z/\hbar)|jm_j\rangle = g_J \mu_B m_j B \qquad \text{for } B \to 0. \tag{4.199}$$

This expression corresponds to the *low-field tangents* indicated by the dotted lines in Fig. 4.16. As was to be expected, also the effective Hamiltonian (4.198) is diagonal in the $\{|nlsjm_j\rangle\}$ basis if the quantization axis is chosen along the direction of the $\mathbf{B}$ field. Our task is of course to determine the value of g_J.

Problem 4.12. Show that the fine-structure levels of a one-electron atom are coupled by the Zeeman interaction.

Solution. We show this for the orbital Zeeman interaction. Since L_z conserves $m_j = m_l + m_s$, we have to show $\langle j'm|L_z|jm\rangle \neq 0$ for $j' \neq j$, where $m = m_{j'} = m_j$. First we do a Clebsch-Gordan decomposition to the uncoupled representation using the triangle inequality $l - \frac{1}{2} \leq j \leq l + \frac{1}{2}$ as well as the projection conservation rule (J.5),

$$|jm\rangle = |l(m-\tfrac{1}{2}); \tfrac{1}{2}\tfrac{1}{2}\rangle\langle l(m-\tfrac{1}{2}); \tfrac{1}{2}\tfrac{1}{2}|jm\rangle + |l(m+\tfrac{1}{2}); \tfrac{1}{2} - \tfrac{1}{2}\rangle\langle l(m+\tfrac{1}{2}); \tfrac{1}{2} - \tfrac{1}{2}|jm\rangle.$$

Using this decomposition we obtain for the matrix element

$$\begin{aligned}\langle j'm|L_z|jm\rangle = {} & (m-\tfrac{1}{2})\langle j'm|l(m-\tfrac{1}{2}); \tfrac{1}{2}\tfrac{1}{2}\rangle\langle l(m-\tfrac{1}{2}); \tfrac{1}{2}\tfrac{1}{2}|jm\rangle \\ & + (m+\tfrac{1}{2})\langle j'm|l(m+\tfrac{1}{2}); \tfrac{1}{2} - \tfrac{1}{2}\rangle\langle l(m+\tfrac{1}{2}); \tfrac{1}{2} - \tfrac{1}{2}|jm\rangle,\end{aligned}$$

which is nonzero if $j' = l \pm \frac{1}{2}$ for $j = l \mp \frac{1}{2}$, with $m = \pm j$ or $m = \mp j'$. □

4.7.5.1 Wigner-Eckart theorem

To understand the relation between Eqs. (4.196) and (4.199) we recall the vector diagram in Fig. 4.6. The slow precession of $\mathbf{J} = \mathbf{L} + \mathbf{S}$ about the direction of a weak probe field (just serving to define a quantization axis) does not affect the projections of the angular momentum operators. As L_z and S_z commute with J_z these operators are invariant under rotation about the z axis; i.e., diagonal in the $\{|nlsjm_j\rangle\}$ basis. The matrix elements of L_z and S_z can be written in the form

$$\langle nlsjm_j| L_z |nlsjm_j\rangle = \langle lsj\, \|L\|\, lsj\rangle \, \langle jm_j| J_z |jm_j\rangle \tag{4.200a}$$

$$\langle nlsjm_j| S_z |nlsjm_j\rangle = \langle lsj\, \|S\|\, lsj\rangle \, \langle jm_j| J_z |jm_j\rangle , \tag{4.200b}$$

where the proportionality constants $\langle lsj\, \|L\|\, lsj\rangle$ and $\langle lsj\, \|S\|\, lsj\rangle$ are known as *reduced matrix elements*. They deserve special attention because they turn out to be *independent of* m_j. Since $J_z = L_z + S_z$ we find by adding Eqs. (4.200a) and (4.200b) that the reduced matrix elements add up to unity,

$$\langle lsj\, \|L\|\, lsj\rangle + \langle lsj\, \|S\|\, lsj\rangle = 1 = \langle lsj\, \|J\|\, lsj\rangle. \tag{4.201}$$

The above is intuitively clear from the vector diagram in Fig. 4.6. The projections of $\mathbf{L}$ and $\mathbf{S}$ along the total angular momentum vector $\mathbf{J}$, i.e. $\mathbf{L}\cdot\mathbf{J}$ and $\mathbf{S}\cdot\mathbf{J}$, are conserved while $\mathbf{J}$ precesses about $\mathbf{B}$,

$$\langle nlsjm_j| L_z |nlsjm_j\rangle = \frac{\langle lsjm_j| (\mathbf{L}\cdot\mathbf{J})\, J_z |lsjm_j\rangle}{\langle lsjm_j| \mathbf{J}^2 |lsjm_j\rangle}. \tag{4.202}$$

Since $\mathbf{L}\cdot\mathbf{J}$ and J_z are both diagonal in the low-field basis (see Problem 4.13) we can factorize the matrix element into the form (4.200a), where the m_j-independent part is given by

$$\langle lsj\, \|L\|\, lsj\rangle = \frac{\langle lsjm_j| \mathbf{L}\cdot\mathbf{J} |lsjm_j\rangle}{\langle lsjm_j| \mathbf{J}^2 |lsjm_j\rangle} = \frac{j(j+1) + l(l+1) - s(s+1)}{2j(j+1)}. \tag{4.203}$$

An alternative derivation of this expression (not relying on the geometric argument presented here) is given in Problem 4.14. Eqs. (4.200) and similar expressions for the other vector components (including the shift operators) follow from the Wigner-Eckart theorem of group theory for the case of vector operators (cf. Appendix K.3.4). Importantly, the three components of the vector operators share the same reduced matrix element,

$$\langle nlsjm_j| L_z |nlsjm_j\rangle = \langle lsj\, \|L\|\, lsj\rangle \, \langle jm_j| J_z |jm_j\rangle \tag{4.204a}$$

$$\langle nlsj(m_j \pm 1)| L_\pm |nlsjm_j\rangle = \langle lsj\, \|L\|\, lsj\rangle \, \langle j(m_j \pm 1)| J_\pm |jm_j\rangle . \tag{4.204b}$$

These expressions embody the *vector projection rule* of coupled angular momenta.

4.7.5.2 Landé factor g_J

In search for g_J we return to Eqs. (4.196) and (4.199). With the aid of the Wigner-Eckart theorem (4.200) as well as the relation (4.201) we obtain the expression

$$\begin{aligned} g_J &= g_L \langle lsj\, \|L\|\, lsj\rangle + g_e \langle lsj\, \|S\|\, lsj\rangle \\ &= \tfrac{1}{2}(g_L + g_e) + \tfrac{1}{2}(g_L - g_e)\left[\langle lsj\, \|L\|\, lsj\rangle - \langle lsj\, \|S\|\, lsj\rangle\right]. \end{aligned} \tag{4.205}$$

Substituting the expressions for the reduced matrix elements (see above or Problem 4.14)

$$\langle lsj\, \|L\|\, lsj\rangle = \frac{j(j+1) + l(l+1) - s(s+1)}{2j(j+1)} \tag{4.206a}$$

$$\langle lsj\, \|S\|\, lsj\rangle = \frac{j(j+1) + s(s+1) - l(l+1)}{2j(j+1)} \tag{4.206b}$$

Table 4.4: Relative deviation from the free-electron g-value for hydrogen-like atoms; differences between isotopes of a given atom are at the ppb level [11, 4].

	H	Li	Na	K	Rb	Cs	units
$g_J/g_e - 1$	-17.4	$-20.9(1)$	$-23.4(1)$	$-24.3(1)$	$5.9(1)$	$98.5(1)$	ppm

we obtain for the g_J factor,

$$g_J = \tfrac{1}{2}\left(g_L + g_e\right) + \tfrac{1}{2}\left(g_L - g_e\right)\frac{l(l+1) - s(s+1)}{j(j+1)}. \tag{4.207}$$

Approximating $g_L = 1$ and $g_e = 2$ we find that g_J takes the form

$$g_J = 1 + \frac{j(j+1) + s(s+1) - l(l+1)}{2j(j+1)}. \tag{4.208}$$

This expression is called the *Landé factor*. Note that just like the expressions for the high-field limit also the derivation of the expressions for the low-field limit is valid for *arbitrary* values of l and s. For the hydrogen-like atoms we have $s = \frac{1}{2}$ and the Landé factor reduces to the compact form

$$g_J = \begin{cases} 1 \pm \dfrac{1}{2l+1} & \left(j = l \pm \tfrac{1}{2}\right) \quad \text{for } l > 0 \\ 2 & \qquad\qquad\quad\;\; \text{for } l = 0. \end{cases} \tag{4.209}$$

Note that in this important case the g_J factor is always *positive* ($g_J > 0$) and largest for the state with the largest multiplicity (highest j).

In the important case of electronic s states Eq. (4.207) reduces to $g_J = g_e$ as expected for the absence of an orbital moment. However, due to confinement of the electron inside the atom, g_J differs slightly from the free-electron g_e value. These deviations are summarized for hydrogen-like atoms in Table 4.4. For the hydrogen atom $g_J(H)/g_e - 1 = -17.4(1.0) \times 10^{-6}$, which means that in hydrogen the electron g factor is reduced by 17.4 ppm [7]. The value of g_J cannot be determined without consideration of the nuclear properties because of coupling of the electronic and nuclear magnetic moments (see Chapter 5). Therefore, precision measurement of g_J requires analysis of the atomic hyperfine structure [11].

Problem 4.13. Derive the operator identity

$$\mathbf{L} \cdot \mathbf{J} = \tfrac{1}{2}[\mathbf{J}^2 + \mathbf{L}^2 - \mathbf{S}^2].$$

Solution. Since $\mathbf{J} = \mathbf{L} + \mathbf{S}$ we find

$$\mathbf{L} \cdot \mathbf{J} = \mathbf{L}^2 + \mathbf{L} \cdot \mathbf{S} = \mathbf{L}^2 + \tfrac{1}{2}[\mathbf{J}^2 - \mathbf{L}^2 - \mathbf{S}^2] = \tfrac{1}{2}[\mathbf{J}^2 + \mathbf{L}^2 - \mathbf{S}^2]. \qquad \square$$

Problem 4.14. Derive the relation

$$\langle lsj \,\|L\|\, lsj\rangle = \frac{j(j+1) + l(l+1) - s(s+1)}{2j(j+1)}.$$

Solution. To determine $\langle lsj \,\|L\|\, lsj\rangle$ we evaluate the operator $\mathbf{S}^2 = (\mathbf{J} - \mathbf{L})^2 = \mathbf{J}^2 + \mathbf{L}^2 - 2\mathbf{J} \cdot \mathbf{L}$ (note that $\mathbf{J} \cdot \mathbf{L} = \mathbf{L} \cdot \mathbf{J}$) in the coupled representation,

$$\langle lsjm_j|\, \mathbf{S}^2 \,|lsjm_j\rangle = \langle lsjm_j|\, \mathbf{J}^2 + \mathbf{L}^2 - 2\mathbf{L} \cdot \mathbf{J} \,|lsjm_j\rangle\,.$$

Comparing the left-hand with the right-hand side we obtain

$$s(s+1) = j(j+1) + l(l+1) - 2\,\langle lsjm_j|\, \mathbf{L} \cdot \mathbf{J} \,|lsjm_j\rangle\,/\hbar^2.$$

With the aid of the inner-product rule (3.159b) and using Wigner-Eckart theorem (4.204) this relation becomes

$$\begin{aligned} s(s+1) &= j(j+1)+l(l+1)-2\langle lsjm_j|\, L_zJ_z+\tfrac{1}{2}[L_+J_-+L_-J_+]\,|lsjm_j\rangle/\hbar^2 \\ &= j(j+1)+l(l+1)-2\langle lsj\,\|L\|\,lsj\rangle\langle lsjm_j|J_z^2+\tfrac{1}{2}[J_+J_-+J_-J_+]\,|lsjm_j\rangle/\hbar^2 \\ &= j(j+1)+l(l+1)-2\langle lsj\,\|L\|\,lsj\rangle\langle lsjm_j|\mathbf{J}^2\,|lsjm_j\rangle/\hbar^2 \\ &= j(j+1)+l(l+1)-2\langle lsj\,\|L\|\,lsj\rangle j(j+1). \end{aligned}$$

Solving for $\langle lsj\,\|L\|\,lsj\rangle$ we obtain the desired relation. □

4.7.6 Example for hydrogen-like atoms

In Fig. 4.16 the low-field limit can be recognized for the case $l=1$, $s=\frac{1}{2}$, assuming $g_L=1$ and $g_e=2$. For $j=l-s=\frac{1}{2}$ we calculate the Landé result $g_J=2/3$; for $j=l+s=\frac{3}{2}$ we have $g_J=4/3$. As shown by the solid lines in Fig. 4.16, in low field ($B\to 0$) we note that

- the 4-fold degeneracy of the ${}^2P_{3/2}$ level is lifted in accordance with

  $$\Delta E_{n,j=3/2,m_j} \simeq \Delta E_{n,3/2}+\tfrac{4}{3}\mu_B m_j B, \tag{4.210}$$

  where $m_j=\pm\frac{1}{2},\pm\frac{3}{2}$. Decomposing $|j,m_j\rangle=\sum_{m_l m_s}|lm_l;sm_s\rangle\langle lm_l;sm_s|jm_j\rangle$ the corresponding eigenstates can be written as

  $$|\tfrac{3}{2},\pm\tfrac{3}{2}\rangle = |1,\pm1;\tfrac{1}{2},\pm\tfrac{1}{2}\rangle \tag{4.211}$$

  $$|\tfrac{3}{2},\pm\tfrac{1}{2}\rangle = \sqrt{2/3}|1,0;\tfrac{1}{2},\pm\tfrac{1}{2}\rangle+\sqrt{1/3}|1,\pm1;\tfrac{1}{2},\mp\tfrac{1}{2}\rangle, \tag{4.212}$$

  where the Clebsch-Gordan coefficients $\langle lm_l;sm_s|jm_j\rangle$ are taken from Appendix J.2.1 for the case of $(1\times 1/2)$ coupling. Here the phase factors are unity because this is a case of maximal j. Note that the correct amplitudes of the coefficients are also obtained using Eq. (4.185) in the limit $B\to 0$. Hence, as we now have also established the sign, the full field dependence of the coefficients is known.

- the two-fold degeneracy of the ${}^2P_{1/2}$ level is lifted like

  $$\Delta E_{n,j=1/2,m_j} \simeq \Delta E_{n,1/2}+\tfrac{2}{3}\mu_B m_j B, \tag{4.213}$$

  with $m_j=\pm\frac{1}{2}$. In this case the eigenstates are

  $$|\tfrac{1}{2},\pm\tfrac{1}{2}\rangle = \mp\sqrt{1/3}|1,0;\tfrac{1}{2},\pm\tfrac{1}{2}\rangle\pm\sqrt{2/3}|1,\pm1;\tfrac{1}{2},\mp\tfrac{1}{2}\rangle, \tag{4.214}$$

  where the Clebsch-Gordan coefficients $\langle lm_l sm_s|jm_j\rangle$ are again taken from Appendix J.2.1 for the case of $(1\times 1/2)$ coupling. Also in this case the amplitude of the coefficients are obtained using Eq. (4.185) in the limit $B\to 0$.

5

Magnetic hyperfine structure

The term *hyperfine structure* is reserved for features of the atomic structure that arise from properties of the nucleus. From Chapter 1 we recall the *effective mass* correction, which accounts for the influence of the nuclear mass on the size of the electronic orbits. Likewise, the *nuclear volume* correction corrects for the non-zero nuclear volume (see Problem 4.1). The most prominent hyperfine features result from the magnetic dipole moment and electric quadrupole moment of the nucleus. The magnetic dipole moment, μ_I, is related to the *nuclear spin*, I, and gives rise to the *magnetic* hyperfine structure. The electric quadrupole moment, Q, arises from the *nuclear shape* and contributes to the *electric* hyperfine structure.

The existence of nuclear spin was conjectured by Wolfgang Pauli in 1924 in relation to observations of hyperfine structure in optical spectra [79]. The related phenomenology was demonstrated by Back and Goudsmit in 1928 [6]. However, as hyperfine shifts and splittings can be as much as a factor 1000 smaller than those of the fine structure, spectral resolution becomes an issue for precision measurements. Therefore, it took the invention of radio-frequency spectroscopy in atomic beams by Isodor Rabi in 1939 [84] before the hyperfine structure could be fully explored. The Rabi method was turned into a modern precision method by Norman Ramsey in 1949 [88, 87]. For the alkali atoms the experimental status was reviewed in 1977 [4]. Since the invention of optical frequency combs by Theodore Hänsch [55] and John Hall [53], hyperfine structure is studied with high-resolution optical spectroscopy (see e.g. [97]).

Although the nuclear properties are determined by the constituent particles (*nucleons* - protons and neutrons) and their orbits inside the nucleus, remarkably little detailed knowledge of nuclear and high-energy physics is required to understand a lot of the atomic hyperfine structure. For atomic spectroscopy it is important to know that the forces between the nucleons *conserve parity* in almost all practical cases. In exceptional cases the weak interaction (which does not conserve parity) plays a role. In any case, we do not have to deal with many other challenging issues of the nucleus. For instance, the structure of the nucleons is highly non-trivial because the interactions between the quarks (the building blocks of the nucleons) cannot be treated perturbatively. In this respect, the name *proton spin puzzle* of quantum chromodynamics (QCD) speaks for itself [2]: why is the spin of the proton 1/2 ? The quark spins (each spin-$\frac{1}{2}$) turn out to account for only some 30% of its value, and the largest contribution is attributed to a combination of the gluon spin (spin-1) and the orbital motion of quarks and gluons.

In this chapter we introduce the magnetic hyperfine structure of *one-electron atoms*. As for the fine structure we focus on atomic systems in which a *single* electron dominates the electronic angular momentum properties. Hence, the electronic states remain *electron spin doublets* ($s = \frac{1}{2}$) of varying orbital angular momentum. However, also non-hydrogen-like features arise. Aside from the spin of the valence electron, also the *spin of the core electrons* (core polarization - see Section 10.4.2) as well as the nuclear *spin* (this chapter) and *shape* (next chapter) play a role.

In view of the above we introduce the atomic hyperfine structure in two rounds. In the present chapter we focus on the *magnetic* hyperfine structure as observed in the hydrogen atom and in the ground states of the alkali elements. In the former case the core does not have to be addressed because core electrons are simply absent, in the latter the core may affect the results quantitatively but qualitatively the hyperfine structure remains hydrogen like. Further we comment on cases in which the core cannot be neglected such as for the $l > 0$ excited states (^2P, ^2D terms) of the alkali elements. In Chapter 6 we shall focus on the *electric* hyperfine structure. As we shall find, in hydrogen ($I = \frac{1}{2}$) the electric hyperfine structure is absent because the nucleus is spherical. For $I > \frac{1}{2}$ (as is the case for many alkali atoms) the nuclei are nonspherical. This affects the hyperfine structure but is of no consequence for the electronic ground states of the alkali atoms because the electronic charge distribution is spherical (^2S terms) and the coupling to electric multipole moments averages to zero.

Thus the present chapter serves to introduce the principal features of the magnetic hyperfine structure, including the Zeeman effect. We emphasize the formal similarity with the phenomenology of the fine structure. In Chapter 6 we turn to the *electric* hyperfine structure. These two chapters cover the backbone of the non-relativistic theory for the hyperfine structure of free atoms. This being said we should be aware that interesting anomalies immediately arise once we deviate from the elementary picture of a non-relativistic one-electron atom with a homogeneously charged classical nucleus. A comprehensive introduction falls outside the scope of this introductory text but can be found in the book by Lloyd Armstrong [5].

5.1 Nuclear magnetic coupling

5.1.1 Nuclear Zeeman coupling

Any charged particle with angular momentum gives rise to a magnetic moment and the atomic nucleus is no exception to this rule. Therefore, just as we associated the electronic spin Zeeman energy to the electron spin, the nuclear spin gives rise to a nuclear spin Zeeman contribution. Writing the Hamiltonian for the magnetic energy in the generic form of a Zeeman interaction we have

$$\mathcal{H}_Z = -\boldsymbol{\mu}_I \cdot \mathbf{B}, \tag{5.1}$$

where

$$\boldsymbol{\mu}_I = \gamma_I \mathbf{I} \equiv g_I \mu_N (\mathbf{I}/\hbar) \tag{5.2}$$

is the *nuclear magnetic moment*, with $\mathbf{I}$ the nuclear spin, γ_I the *gyromagnetic ratio* of the nucleus, g_I the *nuclear g factor* and

$$\mu_N \equiv e\hbar/2m_p = (m_e/m_p)\mu_B \tag{5.3}$$

the *nuclear magneton*, $\mu_N \simeq 5\times10^{-27}$ J/T. Note that $e\hbar/2m_p$ is the gyromagnetic ratio of a classical rotating body of charge e and mass equal to the proton mass m_p. The g_I can be positive or negative, which is an important indicator that the nucleus is more than a simple rotating cloud of positive charge; aside from the rotational motion, also the intrinsic spins of the nucleons contribute to the moment. The quantum numbers I and m_I define the nuclear spin state. In analogy to the orbital case (4.66) the *magnitude* of the nuclear magnetic moment (short: *the* nuclear moment) is defined as the maximum observable nuclear moment (i.e., the value obtained for $m_I = I$),

$$\mu_I \equiv g_I \mu_N I. \tag{5.4}$$

For the nuclear spin quantum number I we shall use capitals rather than the lower-case notation used for the angular momentum quantum numbers of a single electron (s, l and j). The g factor is related to the gyromagnetic ratio of the nucleus,

$$\gamma_I \equiv g_I \mu_N/\hbar. \tag{5.5}$$

Table 5.1: Nuclear spin, nuclear moments and ground-state hyperfine constant and crossover field for selected isotopes [4] (Ca data from [12]). In the literature authors often avoid the nuclear magneton and use a different sign convention for the nuclear g factor: $g_I' = -g_I(m_e/m_p)$.

^{137}Ba	3/2	0.6249	0.937365	4.634	0.245	-		-

As we do not enter into the internal structure of the nucleus we simply treat γ_I as an empirical value. Recalling the discussion of Section 4.3.4 we infer that the torque on the nuclear spin is given by

$$d\mathbf{I}(t)/dt = \boldsymbol{\mu}_I \times \mathbf{B}. \tag{5.6}$$

This torque gives rise to precession of **I** about **B** at angular frequency

$$\boldsymbol{\omega}_I = \gamma_I \mathbf{B}. \tag{5.7}$$

For a free proton the gyromagnetic ratio is given by $\gamma_p = g_p(e/2m_p) = g_p\mu_N/\hbar$, with $\gamma_p/2\pi \simeq 4.26$ kHz/Gauss and $g_p \simeq 5.5857$ being the proton g factor. Likewise, for the deuteron $g_d \simeq 0.8574$ and we calculate with $\gamma_d = g_d\mu_N/\hbar$ for the gyromagnetic ratio $\gamma_d/2\pi \simeq 0.653\,59$ kHz/Gauss. For some selected isotopes the values are tabulated in Table 5.1. Note that the nuclear magneton is a factor $\mu_B/\mu_N = m_p/m_e \simeq 1836.2$ smaller than the Bohr magneton. Therefore, the nuclear-spin Zeeman coupling is typically three orders of magnitude weaker than the electronic-spin Zeeman coupling introduced in Section 4.3.5. As a result this coupling only weakly perturbs the atomic fine structure discussed in Chapter 4. Substituting Eq. (5.2) into the Zeeman Hamiltonian (5.1) the nuclear Zeeman term takes the form

$$\mathcal{H}_Z = -\gamma_I \mathbf{I} \cdot \mathbf{B} = -g_I \mu_N B \left(I_z/\hbar \right), \tag{5.8}$$

where the z direction is again chosen along the direction of the **B** field. This Hamiltonian expresses the coupling of **I** to the **B** field (*nuclear Zeeman coupling*).

We analyze the level splitting by the nuclear spin Zeeman coupling in the same way as we did for the electron spin Zeeman coupling using ordinary first-order perturbation theory.[1] For the nuclear spin Zeeman term this is done in the hydrogenic basis further extended by a spin sector $\{|nlm_l s m_s\rangle\} \to \{|nlm_l s m_s I m_I\rangle\}$, $\Delta E_Z = \langle nlm_l s m_s I m_I|\mathcal{H}_Z|nlm_l s m_s I m_I\rangle$. Since $\mathbf{I}^2$ and I_z commute with $\mathcal{H}_0$, $\mathbf{L}^2$, L_z, $\mathbf{S}^2$ and S_z the nuclear spin Zeeman operator acts in a $2I+1$ dimensional sector of Hilbert space and is *diagonal* in the spin basis $\{|I m_I\rangle\}$; i.e., I and m_I are good quantum numbers. The nuclear-Zeeman energy shift is given by

$$\Delta E_Z = -\gamma_I B \langle I, m_I|I_z|I, m_I\rangle = -g_I \mu_N m_I B. \tag{5.9}$$

5.1.2 Total atomic angular momentum

As long as we may neglect the interaction with the environment (i.e., in zero field) the atom represents a closed mechanical system and the *total angular momentum* is a conserved quantity. In the presence of hyperfine interaction this quantity is denoted by **F**. In hydrogen-like atoms it results from the contribution of three angular momenta,

$$\mathbf{F} = \mathbf{L} + \mathbf{S} + \mathbf{I}. \tag{5.10}$$

Since the addition of three angular momenta can be done in different ways it is an important simplifying factor that the coupling of the nuclear spin to the other angular momenta is weak, much weaker than the coupling between **L** and **S**. Therefore, we may (and shall) presume that the nuclear spin couples only to the total electronic angular momentum $\mathbf{J} = \mathbf{L} + \mathbf{S}$ rather than to **L** and **S** separately. In this way the hyperfine structure of the atom can be obtained by considering the coupling of only two angular momenta,[2]

$$\mathbf{F} = \mathbf{J} + \mathbf{I}. \tag{5.11}$$

Starting from this expression it is straightforward to show that **F** obeys commutation relations of the type (1.29),

$$[F_x, F_y] = i\hbar F_z,\ [F_y, F_z] = i\hbar F_x \text{ and } [F_z, F_x] = i\hbar F_y. \tag{5.12}$$

Therefore, **F** satisfies all properties of quantized angular momenta,

$$\mathbf{F}^2 \left|jIF, m_F\right\rangle = F(F+1)\hbar^2 \left|jIF, m_F\right\rangle \tag{5.13}$$

$$F_z \left|jIF, m_F\right\rangle = m_F \hbar \left|jIF, m_F\right\rangle, \tag{5.14}$$

with m_F restricted to the interval

$$-F \leq m_F \leq F. \tag{5.15}$$

In many cases the specification of j and I is irrelevant because their value is obvious from the context. In such cases these quantum numbers are usually omitted in the notation, writing simply $|F, m_F\rangle$ rather than $|jIF, m_F\rangle$. For given values of j and I the value of F can vary from $|j-I|$ to $j+I$ in steps of unit angular momentum in accordance with the *triangle inequality*

$$|j-I| \leq F \leq j+I. \tag{5.16}$$

---

[1] Pure nuclear spin Zeeman splitting is observed in isotopes of closed shell atoms (e.g., the inert gases). In one-electron atoms nuclear spin Zeeman coupling does not occur without hyperfine interaction (see later in this chapter).

[2] In heavy many-electron atoms the identity $\mathbf{J} = \mathbf{L} + \mathbf{S}$ is *not* satisfied (see jj coupling - Section 10.6.3). However, irrespective of the detailed coupling scheme, **J** remains well defined and Eq. (5.11) remains valid in zero field.

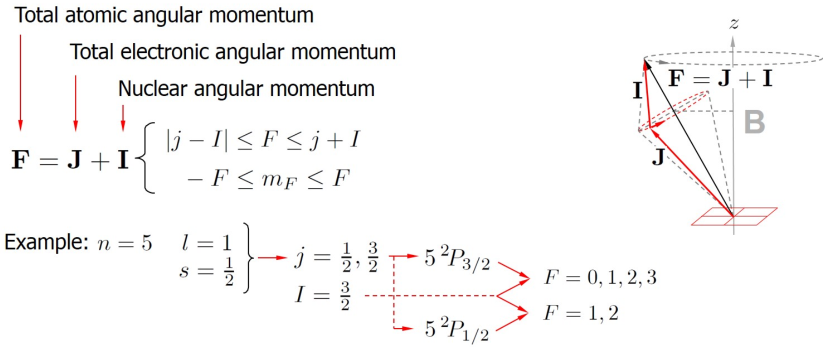

Figure 5.1: Addition of angular momenta in the presence of nuclear spin, presuming $\mathbf{L}\cdot\mathbf{S}$ coupling at the fine-structure level. The precession along the z axis occurs when the symmetry is broken by a non-zero magnetic field in this direction.

Note that F can become zero (unlike j in the case of the fine structure of hydrogen-like atoms). This happens for $j=I$. The actions of the shift operators $F_\pm$ are given by Eq. (3.24),

$$F_\pm\,|F,m_F\rangle=\sqrt{F\,(F+1)-m_F(m_F\pm 1)}\hbar\,|F,m_F\pm 1\rangle\,. \tag{5.17}$$

Since j, I and F are quantized the coupling of $\mathbf{I}$ and $\mathbf{J}$ cannot exist without their joint precession about $\mathbf{F}$ as is illustrated in Fig. 5.1. In view of this precession $\mathbf{I}$ and $\mathbf{J}$ are clearly not conserved. The conservation of $\mathbf{F}$ is lost when a nonzero magnetic field $\mathbf{B}$ breaks the symmetry. This gives rise to a precession of $\mathbf{F}$ about the field direction as is also indicated in Fig. 5.1.

The operator $\mathbf{F}$ acts in a $(2F+1)$-dimensional subspace of the full $(2j+1)\,(2I+1)$-dimensional product space defined by the so-called *uncoupled basis* $\{|jm_jIm_I\rangle\equiv|jm_j\rangle\otimes|Im_I\rangle\}$. Together the $(2F+1)$-dimensional subspaces of all possible values of F allowed by the triangular inequality provide the so-called *coupled basis* $\{|jIFm_F\rangle\}$ of the same $(2j+1)\,(2I+1)$-dimensional product space. Since F_z commutes with both J_z and I_z we know that these operators are diagonal in both bases and, since $F_z=J_z+I_z$, the magnetic quantum numbers are related by

$$m_F=m_j+m_I. \tag{5.18}$$

Note that this is the selection rule (3.89).

5.2 Magnetic hyperfine interaction

5.2.1 Introduction

The magnetic hyperfine interaction finds its origin in the coupling of the magnetic moment of the nucleus to the degrees of freedom of the electron and to the external magnetic field $\mathbf{B}$. Approximating the nucleus by a point dipole, $\boldsymbol{\mu}_I$, its contribution to the vector potential is given by

$$\mathbf{A}_I\,(\mathbf{r})=\frac{\mu_0}{4\pi}\frac{\boldsymbol{\mu}_I\times\mathbf{r}}{r^3}, \tag{5.19}$$

where $\mathbf{r}$ is the usual operator for the position of the electron relative to the nucleus (see Fig. 5.2). The corresponding magnetic field is the nuclear magnetic dipole field (see Problem 5.1),

$$\mathbf{B}_I\,(\mathbf{r})=\nabla\times\mathbf{A}_I\,(\mathbf{r})=\frac{\mu_0}{4\pi}\frac{1}{r^3}[3\,(\boldsymbol{\mu}_I\cdot\hat{\mathbf{r}})\,\hat{\mathbf{r}}-\boldsymbol{\mu}_I]+\tfrac{2}{3}\mu_0\boldsymbol{\mu}_I\delta\,(\mathbf{r})\,. \tag{5.20}$$

This field consists of two contributions: the first term is the ordinary nuclear dipole field, observable *outside* the nucleus; the second term accounts for the field *inside* the nucleus.

In the Coulomb gauge, $\nabla\cdot\mathbf{A}=0$, the atomic Hamiltonian, including hyperfine interaction, takes the form

$$\mathcal{H}=-\frac{\hbar^2}{2m_r}\Delta+\mathcal{V}(r)+\mathcal{H}_r-\frac{i\hbar e}{m_r}\mathbf{A}\cdot\boldsymbol{\nabla}+\frac{e^2}{2m_r}\mathbf{A}^2-\boldsymbol{\mu}_s\cdot(\mathbf{B}_{LS}+\mathbf{B}_I+\mathbf{B})-\boldsymbol{\mu}_I\cdot\mathbf{B}. \tag{5.21}$$

The latter two terms are related to the postulated spins of electron and nucleus. They represent the interaction of $\boldsymbol{\mu}_s$ with the spin-orbit field ($\mathbf{B}_{LS}$), the nuclear dipole field ($\mathbf{B}_I$) and the external field (spin Zeeman term), and further the interaction of $\boldsymbol{\mu}_I$ with the external field (nuclear Zeeman term). The $\mathbf{A}\cdot\boldsymbol{\nabla}$ term represents the sum of the orbital Zeeman coupling (coupling of the orbital motion of the electron to the external field $\mathbf{B}$ - see Section 4.2) and the nuclear-spin-orbit coupling (coupling of the orbital motion to the nuclear field $\mathbf{B}_I$). Separating the principal structure and fine-structure terms from the rest of the Hamiltonian, Eq. (5.21) can be expressed as the sum of 5 contributions

$$\mathcal{H}=\mathcal{H}_0+\mathcal{H}_r+\mathcal{H}_{LS}+\mathcal{H}_{\text{hfs}}+\mathcal{H}_Z, \tag{5.22}$$

where $\mathcal{H}_0$ is the Schrödinger Hamiltonian, H_r the relativistic correction term, $\mathcal{H}_{LS}$ the spin-orbit Hamiltonian (4.117),

$$\mathcal{H}_Z=-(\boldsymbol{\mu}_L+\boldsymbol{\mu}_s+\boldsymbol{\mu}_I)\cdot\mathbf{B} \tag{5.23}$$

the Zeeman Hamiltonian and

$$\mathcal{H}_{\text{hfs}}=-\frac{i\hbar e}{m_r}\mathbf{A}_I\cdot\boldsymbol{\nabla}+\frac{e^2}{2m_r}\mathbf{A}_I^2-\boldsymbol{\mu}_s\cdot\mathbf{B}_I \tag{5.24}$$

the magnetic hyperfine contribution. The $\mathbf{A}_I^2$ term may be neglected because its contribution is much smaller than the contribution of the terms linear in $\mathbf{A}_I$. A similar approximation was made in the case of the fine structure; at a distance of the Bohr radius from the nucleus the nuclear field in hydrogen is far too weak to induce any appreciable magnetic polarization, $\mathbf{B}_I\,(a_0)\simeq 10^{-2}$ T.

Problem 5.1. The magnetic field of a point dipole is given by

$$\mathbf{B}_I=\frac{\mu_0}{4\pi}\frac{1}{r^3}[3\,(\boldsymbol{\mu}_I\cdot\hat{\mathbf{r}})\,\hat{\mathbf{r}}-\boldsymbol{\mu}_I]+\tfrac{2}{3}\mu_0\boldsymbol{\mu}_I\delta(\mathbf{r}).$$

Derive this expression starting from the expression for the vector potential of the dipole field outside a homogeneous magnetized sphere, $\mathbf{A}_I=(\mu_0/4\pi)\,(\boldsymbol{\mu}_I\times\mathbf{r})\,/r^3$, and the vector potential $\mathbf{A}=\frac{1}{2}(\mathbf{B}\times\mathbf{r})$ of a homogeneous field inside the sphere (see Fig.5.2).

Solution. (*a*) Using Eq. (N.9) the magnetic field $\mathbf{B}_I=\boldsymbol{\nabla}\times\mathbf{A}_I$ of the nuclear magnetic moment outside the nucleus can be written as

$$(4\pi/\mu_0)\,\mathbf{B}_I=\boldsymbol{\nabla}\times(\boldsymbol{\mu}_I\times\mathbf{r})\,/r^3=-(\boldsymbol{\mu}_I\cdot\boldsymbol{\nabla})\mathbf{r}/r^3+\boldsymbol{\mu}_I(\boldsymbol{\nabla}\cdot\mathbf{r}/r^3).$$

This can be reformulated in the form

$$(4\pi/\mu_0)\,\mathbf{B}_I=-r^{-3}(\boldsymbol{\mu}_I\cdot\boldsymbol{\nabla})\mathbf{r}-\mathbf{r}\left(\boldsymbol{\mu}_I\cdot\boldsymbol{\nabla}r^{-3}\right)+r^{-3}\boldsymbol{\mu}_I(\boldsymbol{\nabla}\cdot\mathbf{r})+\boldsymbol{\mu}_I\left(\mathbf{r}\cdot\boldsymbol{\nabla}r^{-3}\right).$$

Using Eqs. (N.13), (N.11) and (N.18) we obtain after collecting terms the first two terms of the expression for the dipole field.
(*b*) At the surface of a homogeneously magnetized sphere of radius R the vector potential becomes

$$\mathbf{A}|_{r=R}=\tfrac{1}{2}(\mathbf{B}\times\mathbf{r})|_{r=R}=(\mu_0/4\pi)\,(\boldsymbol{\mu}_I\times\mathbf{r})\,/r^3|_{r=R},$$

which implies $\mathbf{B}=(\mu_0/2\pi)\,\mu_0\boldsymbol{\mu}_I/R^3$. Integrating the field over the volume of the sphere we obtain

$$\int_0^{(4/3)\pi R^3}\mathbf{B}(\mathbf{r})d\mathbf{r}=\tfrac{2}{3}\mu_0\boldsymbol{\mu}_I\,.$$

The same result is obtained for a point dipole by choosing $\mathbf{B}=\frac{2}{3}\mu_0\boldsymbol{\mu}_I\delta(\mathbf{r})$. □

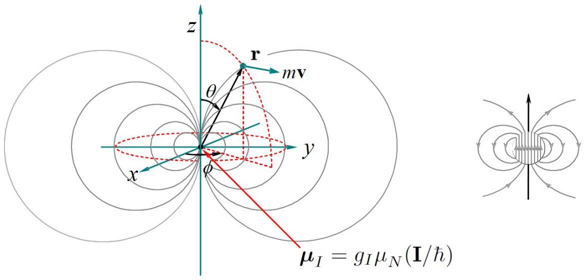

Figure 5.2: *Left*: Electron moving in the magnetic field of the nuclear magnetic dipole. *Right*: Not only the dipole field outside the nucleus but also the field inside the nucleus contributes to the hyperfine interaction. The latter contribution is estimated in the text by treating the nucleus as a homogeneously magnetized sphere of vanishing size (point dipole).

5.2.2 Three contributions to the magnetic hyperfine interaction in zero field

Substituting Eq. (5.19) into the Hamiltonian (5.24) we find that the magnetic hyperfine interaction can be written as the sum of three terms,

$$\mathcal{H}_{\mathrm{hfs}} = \mathcal{H}_{IL} + \mathcal{H}_{dd} + \mathcal{H}_{\mathrm{Fermi}}\,, \tag{5.25}$$

which are sufficient to calculate the level shifts in hydrogen-like atoms.

- the first term follows from $\mathcal{H}_{IL} = -(i\hbar e/m_r)\mathbf{A}_I \cdot \boldsymbol{\nabla}$ and represents the *nuclear-spin-orbit interaction* of the moving electron with the magnetic field of the nucleus. Substituting Eq. (5.19) and using Eqs. (N.1), (4.54), (4.81) and (5.2) this term takes the form [1]

  $$\mathcal{H}_{IL} = 2\frac{g_L}{g_e}\frac{\mu_0}{4\pi}\frac{\gamma_I|\gamma_e|}{r^3}\mathbf{I}\cdot\mathbf{L} \simeq \frac{\mu_0}{4\pi}\frac{\gamma_I|\gamma_e|}{r^3}\mathbf{I}\cdot\mathbf{L}, \tag{5.26}$$

  where we recalled that $2g_L/g_e \simeq 1$.

- the second and third term both follow from $-\boldsymbol{\mu}_s \cdot \mathbf{B}_I(\mathbf{r})$. Substituting Eq. (5.20) and using Eqs. (4.80) and (5.2) we obtain the *magnetic dipole-dipole interaction*

  $$\mathcal{H}_{dd} = \frac{\mu_0}{4\pi}\frac{\gamma_I|\gamma_e|}{r^3}[3\,(\mathbf{I}\cdot\hat{\mathbf{r}})\,(\mathbf{S}\cdot\hat{\mathbf{r}}) - \mathbf{I}\cdot\mathbf{S}] \tag{5.27a}$$

- as well as the *Fermi contact interaction*

  $$\mathcal{H}_{\mathrm{Fermi}} = \tfrac{2}{3}\mu_0\gamma_I|\gamma_e|\delta\,(\mathbf{r})\,\mathbf{I}\cdot\mathbf{S}. \tag{5.28}$$

5.2.3 Magnetic dipole-dipole interaction using spherical tensor operators

Note that the operators $\mathcal{H}_{dd}$ and $\mathcal{H}_{\mathrm{Fermi}}$ are symmetric in the role of the nuclear spin and the electron spin. In other words, we can equally well can say that the electron spin probes the magnetic field of the nucleus or that the nucleus probes the magnetic field of the electron spin. In view of the importance of the interaction between two magnetic dipoles we derive - as an intermezzo - an expression for this interaction in which the central symmetry of the atom is optimally exploited. For two magnetic dipoles, denoted by $\boldsymbol{\mu}_I = \gamma_I\mathbf{I}$ and $\boldsymbol{\mu}_S = \gamma_S\mathbf{S}$, the dipole-dipole interaction takes the following well-known form

$$\mathcal{H}_{dd} = \frac{\mu_0}{4\pi}\frac{1}{r^3}\,[3\,(\boldsymbol{\mu}_I\cdot\hat{\mathbf{r}})\,(\boldsymbol{\mu}_S\cdot\hat{\mathbf{r}}) - \boldsymbol{\mu}_I\cdot\boldsymbol{\mu}_S]\,. \tag{5.29}$$

---

[1] Note that $-i\hbar\,(\boldsymbol{\mu}_I \times \mathbf{r})\cdot\boldsymbol{\nabla} = -i\hbar\boldsymbol{\mu}_I\cdot(\mathbf{r}\times\boldsymbol{\nabla}) = \boldsymbol{\mu}_I\cdot\mathbf{L}$.

The difficulty in evaluating this operator is related to the inner products of the dipoles with the radial direction operator. These inner products complicate the separation of the position dependence from the dependence on angular momentum. For a system of central symmetry this separation is best achieved by decomposition of $\mathcal{H}_{dd}$ in terms of the standard components T_2^m of a rank 2 spherical tensor (see Problem 5.2),

$$\mathcal{H}_{dd} = \frac{\mu_0}{4\pi}\frac{\gamma_S\gamma_I}{r^3}\sqrt{\frac{4\pi}{5}}\sum_{m=-2}^{2}(-1)^m Y_2^{-m}(\hat{\mathbf{r}})T_2^m. \tag{5.30}$$

The operators T_2^m can be expressed in terms of the standard components $I_{\pm1}, I_0$ and $S_{\pm1}, S_0$ of the constituent rank 1 tensors (the vector operators $\mathbf{I}$ and $\mathbf{S}$). Actually, in order to facilitate evaluation of the matrix elements of $\mathcal{H}_{dd}$ in the $\{|sm_s, Im_I\rangle\}$ representation, we do not use the standard components $I_{\pm1}, I_0$ and $S_{\pm1}, S_0$ but rather I_z and S_z and the shift operators $I_\pm$ and $S_\pm$,

$$T_2^0 = 2I_zS_z - \tfrac{1}{2}\left(I_-S_+ + I_+S_-\right), \tag{5.31a}$$

$$T_2^{\pm1} = \mp\left(I_\pm S_z + I_zS_\pm\right)\sqrt{3/2}, \tag{5.31b}$$

$$T_2^{\pm2} = I_\pm S_\pm\sqrt{3/2}. \tag{5.31c}$$

Note that the T_2^m satisfy the commutation relations (K.3), as required for spherical tensor operators. The inclusion of the phase factor $(-1)^m$ in Eq. (5.30) assures that the T_2^m transform like the Y_2^m, hence satisfy the Condon and Shortley phase convention.

Problem 5.2. Verify the tensor decomposition (5.30).

Solution. We first we express the inner products $\mathbf{I}\cdot\hat{\mathbf{r}}$ and $\mathbf{S}\cdot\hat{\mathbf{r}}$ in spherical coordinates (θ and ϕ):

$$\mathbf{I}\cdot\hat{\mathbf{r}} = I_z\cos\theta + I_x\sin\theta\cos\phi + I_y\sin\theta\sin\phi = I_z\cos\theta + \tfrac{1}{2}I_-\sin\theta e^{i\phi} + \tfrac{1}{2}I_+\sin\theta e^{-i\phi}.$$

Replacing $\mathbf{I}$ by $\mathbf{S}$ we obtain $\mathbf{S}\cdot\hat{\mathbf{r}}$. For the product of these inner products we find

$$\begin{aligned}(\mathbf{I}\cdot\hat{\mathbf{r}})\,(\mathbf{S}\cdot\hat{\mathbf{r}}) = I_zS_z\cos^2\theta &+ \tfrac{1}{4}(I_-S_+ + I_+S_-)\sin^2\theta \\ &+ \tfrac{1}{2}(I_zS_- + I_-S_z)\sin\theta\cos\theta\, e^{i\phi} + \tfrac{1}{2}(I_zS_+ + I_+S_z)\sin\theta\cos\theta\, e^{-i\phi} \\ &+ \tfrac{1}{4}I_-S_-\sin^2\theta e^{2i\phi} + \tfrac{1}{4}I_+S_+\sin^2\theta e^{-2i\phi}.\end{aligned}$$

Recalling the inner product rule (3.159b) we have $\mathbf{I}\cdot\mathbf{S} = I_zS_z + \frac{1}{2}\left(I_+S_- + I_-S_+\right)$ and recognizing the spherical harmonics $Y_2^{\pm1}(\hat{\mathbf{r}})$ and $Y_2^{\pm1}(\hat{\mathbf{r}})$ we obtain

$$\begin{aligned}3\,(\mathbf{I}\cdot\hat{\mathbf{r}})\,(\mathbf{S}\cdot\hat{\mathbf{r}}) - \mathbf{I}\cdot\mathbf{S} = I_zS_z(3\cos^2\theta - 1) &+ \tfrac{1}{4}\left(I_+S_- + I_-S_+\right)(3\sin^2\theta - 2) \\ &+ \sqrt{4\pi/5}\left[-\left(I_zS_- + I_-S_z\right)Y_2^1(\hat{\mathbf{r}}) + \left(I_zS_+ + I_+S_z\right)Y_2^{-1}(\hat{\mathbf{r}})\right]\sqrt{3/2} \\ &+ \sqrt{4\pi/5}\left[I_-S_-Y_2^2(\hat{\mathbf{r}}) + I_+S_+Y_2^{-2}(\hat{\mathbf{r}})\right]\sqrt{3/2}.\end{aligned}$$

At this point we identify the $(-1)^qT_2^q$ with the prefactors of $Y_2^{-q}(\hat{\mathbf{r}})$ for $q = \pm1, \pm2$. Since $2 - 3\sin^2\theta = 3\cos^2\theta - 1 = 2\sqrt{4\pi/5}\,Y_2^0(\hat{\mathbf{r}})$ we finally identify T_2^0 with the prefactor of $Y_2^0(\hat{\mathbf{r}})$. □

5.3 Hyperfine interaction in zero field

5.3.1 Introduction - effective Hamiltonian

In the previous section we identified three mechanisms through which the angular momentum of the electron can couple to that of the nucleus. Before continuing with the derivation of the associated coupling coefficients and hyperfine shifts we summarize the main results to be obtained later in this chapter. We shall establish that the three contributions of the *magnetic* hyperfine interaction add up to a *single* effective Hamiltonian,

$$\mathcal{H}_{\mathrm{hfs}} = (\mathcal{A}_{\mathrm{hfs}}/\hbar^2)\,\mathbf{I}\cdot\mathbf{J}, \tag{5.32}$$

where $\mathcal{A}_{\mathrm{hfs}}$ is called the *hyperfine coupling constant.* Note that this Hamiltonian is of the same general form as the spin-orbit Hamiltonian. Within the framework of first-order perturbation theory $\mathcal{H}_{\mathrm{hfs}}$ acts in the $(2j+1)(2I+1)$-degenerate subspace of the fine-structure level $n\,^{2s+1}L_j$. Within this approximation j, I, F and m_F are good quantum numbers, with $-F \le m_F \le F$ (note that $\mathbf{J}^2$, $\mathbf{I}^2$, $\mathbf{F}^2$ and F_z commute with $\mathcal{H}_{\mathrm{hfs}}$). For the electronic ground state the approximation is excellent because the hyperfine splitting is small as compared to the splitting of the principal structure. For the electronically excited states the approximation is only good as long as the fine-structure splitting is sufficiently large. For the time being we distinguish two cases:

- *Hydrogen-like atoms:* For zero orbital angular momentum ($l = 0$) only the *Fermi contact interaction* contributes. In this case we have $\mathbf{J} = \mathbf{S}$ and one uses the lower case notation for the coupling constant, $\mathcal{A}_{\mathrm{hfs}} \to a_{\mathrm{hfs}}$. In this notation Eq. (5.32) takes the form

  $$\mathcal{H}_{\mathrm{hfs}} = (a_{\mathrm{hfs}}/\hbar^2)\,\mathbf{I}\cdot\mathbf{S}, \tag{5.33}$$

  where the coupling constant for the $n\,^{2s+1}L_j$ fine-structure level is given by

  $$a_{\mathrm{hfs}}\left(n\,^{2s+1}L_j\right) = \frac{\mu_0}{4\pi}\frac{2}{3}\gamma_I|\gamma_e|\frac{\hbar^2}{a^3}\tilde{R}^2_{ns}(0) \qquad (l=0)\,. \tag{5.34}$$

- *Hydrogenic atoms:* For $l > 0$ the Fermi contact interaction does not contribute and the form (5.32) follows from the addition of $\mathcal{H}_{IL}$ and $\mathcal{H}_{dd}$. In this case the coupling constant is written in the upper case notation. For the $n\,^{2s+1}L_j$ fine-structure level it is given by

  $$\mathcal{A}_{\mathrm{hfs}}\left(n\,^{2s+1}L_j\right) = \frac{\mu_0}{4\pi}\gamma_I|\gamma_e|\frac{\hbar^2}{a^3}\langle nl||\rho^{-3}||nl\rangle\frac{l(l+1)}{j(j+1)} \qquad (l>0)\,, \tag{5.35}$$

  where $\rho = r/a$ is the reduced distance to the nucleus, $a = (m_e/m_r)a_0$ being the atomic unit of length and m_r the reduced mass of the electron.

Note that $\mathcal{H}_{\mathrm{hfs}}$ is an *effective* Hamiltonian because the radial dependence of the hyperfine interaction is averaged over the orbital wavefunction, thus neglecting the coupling to other manifolds with different principal quantum number. Therefore, it is valid only to first-order in perturbation theory. For reasons of compactness of notation in most cases we do not specify the fine-structure Term but simply write $\mathcal{A}_{\mathrm{hfs}}$ (for $l > 0$) or a_{hfs} (for $l = 0$) for the coupling constant. Importantly, the expressions for $\mathcal{A}_{\mathrm{hfs}}$ and a_{hfs} are both proportional to γ_I. As all other quantities in the definition of the coupling constant are positive the hyperfine shift is *positive* for atoms with *positive* nuclear gyromagnetic ratio and *negative* for atoms where this ratio is *negative.*[1] For selected isotopes the observed ground state coupling constants a_{hfs} are listed in Table 5.1.

To finish this introduction we compare the hyperfine coupling with fine-structure coupling in hydrogenic atoms. Rewriting Eq. (4.135) with the aid of Eq. (4.119) the fine-structure coupling takes the form

$$\zeta_{nl} = \frac{\mu_0}{4\pi}2\gamma_L^2\frac{\hbar^2}{a^3}Z\,\langle nl||\rho^{-3}||nl\rangle. \tag{5.36}$$

---

[1] In many-electron atoms $\mathcal{A}_{\mathrm{hfs}}$ can become negative for positive g_I (see Fig. 5.3). This arises as a result of polarization of the electron core (see Section 10.4.2). Core polarization also affects the value of the ground state hyperfine splitting of alkali atoms but is not strong enough to affect its sign. Hence, the *ground state* hyperfine splitting of the alkali atoms is hydrogen like. For this reason these ground states are discussed in the context of the present chapter.

Comparing this expression with Eq. (5.35) we find for the ratio of the coupling constants

$$\frac{\mathcal{A}_{\mathrm{hfs}}\left(n\,^{2s+1}L_j\right)}{\zeta_{nl}} \simeq \frac{\gamma_I}{|\gamma_L|}\frac{l(l+1)}{j(j+1)}\frac{1}{Z} \qquad (l>0)\,. \tag{5.37}$$

Here we approximated $\gamma_e \simeq 2\gamma_L$. Since $\gamma_I/|\gamma_L| \simeq g_I m_e/m_p$ we find that the hyperfine coupling constant is typically a factor 1000 smaller than the corresponding constant for the fine structure.

5.3.2 Zero-field hyperfine shift in hydrogen-like atoms - the case $l = 0$

We start the derivation of *magnetic* hyperfine shifts with hydrogen-like atoms of zero orbital angular momentum (s states) in the absence of external fields. This case is of considerable importance because all hydrogen-like atoms have $l = 0$ ground states. Note that in the absence of orbital angular momentum also the spin-orbit coupling is absent, which means that only the electronic and nuclear spins contribute to the total angular momentum,

$$\mathbf{F} = \mathbf{S} + \mathbf{I}. \tag{5.38}$$

As the Schrödinger Hamiltonian, $\mathcal{H}_0$, commutes with $\mathbf{I}\cdot\mathbf{S}$ the orbital wavefunctions separate from the spin part, suggesting the basis $\{|nlm_l; sIFm_F\rangle\}$ to calculate the perturbation. Interestingly, as we shall see, to obtain Eq. (5.34) the Fermi contact term (5.28) suffices: $\Delta E_{\mathrm{hfs}} = \Delta E_{\mathrm{Fermi}}$. Factoring out the orbital matrix element $\langle nlm_l|\delta(\mathbf{r})|nlm_l\rangle = \langle n00|\delta(\mathbf{r})|n00\rangle$ and recalling the relation $\delta(r) = 4\pi\delta(\mathbf{r})r^2$, we obtain to first order in perturbation theory

$$\Delta E_{\mathrm{hfs}}(n\,^{2s+1}S_{1/2}) = (a_{\mathrm{hfs}}/\hbar^2)\langle sIFm_F|\mathbf{I}\cdot\mathbf{S}|sIFm_F\rangle, \tag{5.39}$$

where the hyperfine coupling constant is given by

$$\begin{aligned} a_{\mathrm{hfs}}(n\,^{2s+1}S_{1/2}) &= \tfrac{2}{3}\mu_0\gamma_I|\gamma_e|\hbar^2\langle n00|\delta(\mathbf{r})|n00\rangle \\ &= \frac{\mu_0\gamma_I|\gamma_e|\hbar^2}{a^3}\frac{2}{3}\int \delta(\boldsymbol{\rho})\,\tilde{R}^2_{ns}(\rho)\left|Y^0_0(\hat{\boldsymbol{\rho}})\right|^2 d\boldsymbol{\rho} \\ &= \frac{\mu_0}{4\pi}\frac{\gamma_I|\gamma_e|\hbar^2}{a^3}\frac{2}{3}\tilde{R}^2_{ns}(0) \qquad\qquad (l=0) \end{aligned} \tag{5.40}$$

with $\rho = r/a$ being the radial distance in atomic units $a = (m_e/m_r)a_0$ (see Section 2.1). This completes the derivation of Eq. (5.34). A special feature of the delta function is that it does not couple states with different principal quantum number. Hence, with regard to contact interactions n is a good quantum number.

5.3.2.1 Fermi contact suffices for $l = 0$

What about the other terms of the hyperfine Hamiltonian? They turn out to vanish. We shall demonstrate that for s states neither $\mathcal{H}_{IL}$ nor $\mathcal{H}_{dd}$ contribute to the hyperfine shift. For this purpose we choose the basis $\{|nlm_l; sIFm_F\rangle\}$ in which $\mathbf{L}$ is decoupled from $\mathbf{F} = \mathbf{S} + \mathbf{I}$. Note that this choice of basis is both possible and logical for subspaces in which orbital angular momentum is absent; i.e., for $l = m_l = 0$. In this basis the absence of an energy shift is straightforward for the nuclear-spin-orbit interaction $\mathcal{H}_{IL}$,

$$\Delta E_{IL}(n\,^{2s+1}L_j) = 2\frac{g_L}{g_e}\frac{\mu_0}{4\pi}\gamma_I|\gamma_e|\langle n00; sIFm_F|\frac{\mathbf{I}\cdot\mathbf{L}}{r^3}|n00; sIFm_F\rangle = 0, \tag{5.41}$$

because all components of $\mathbf{L}$ yield zero when acting on a state of zero orbital angular momentum.

A bit more effort is required to show that the magnetic dipole-dipole operator ($\mathcal{H}_{dd}$) does not contribute to the $l = 0$ hyperfine shift. We shall find that its contribution averages to zero for *spherical* orbitals. For this purpose we consider the first-order shift in the $\{|n00; sIFm_F\rangle\}$ representation,

$$\Delta E_{dd}(n\,{}^{2s+1}L_j) = \frac{\mu_0}{4\pi}\gamma_I|\gamma_e|\langle n00; sIFm_F|\frac{1}{r^3}\left[3\left(\mathbf{I}\cdot\hat{\mathbf{r}}\right)\left(\mathbf{S}\cdot\hat{\mathbf{r}}\right) - \mathbf{I}\cdot\mathbf{S}\right]|n00; sIFm_F\rangle. \tag{5.42}$$

To separate the position dependence from the spin dependence we express the $\mathcal{H}_{dd}$ in terms of second-order spherical harmonics - see Eq. (5.30)

$$\mathcal{H}_{dd} = \frac{\mu_0}{4\pi}\frac{\gamma_e\gamma_I}{r^3}\sum_{m=-2}^{2} T_2^m Y_2^{-m}(\hat{\mathbf{r}}), \tag{5.43}$$

where the tensor components T_2^m are defined by Eqs. (5.31). Thus we obtain

$$\Delta E_{dd}(n\,{}^{2s+1}L_j) = \frac{\mu_0}{4\pi}\gamma_I\gamma_e\sum_{m=-2}^{2}\langle n00|Y_2^{-m}(\hat{\mathbf{r}})/r^3|n00\rangle\langle sIFm_F|T_2^m|sIFm_F\rangle. \tag{5.44}$$

Note that because the T_2^m are independent of $\mathbf{r}$ we could factor out the $\mathbf{r}$ dependent matrix element

$$\langle n00|Y_2^m(\hat{\mathbf{r}})/r^3|n00\rangle = \int\frac{\left[R_{ns}(r)\right]^2}{r^3}Y_2^m(\hat{\mathbf{r}})|Y_0^0(\hat{\mathbf{r}})|^2 d\mathbf{r}. \tag{5.45}$$

This integral vanishes as follows by evaluating the angular part. Rather than using direct integration, which is straightforward, we demonstrate this with the aid of the general formula (L.58),

$$\int Y_2^m(\hat{\mathbf{r}})|Y_0^0(\hat{\mathbf{r}})|^2 d\hat{\mathbf{r}} = \sqrt{\frac{5}{4\pi}}\begin{pmatrix}0&2&0\\0&0&0\end{pmatrix}\begin{pmatrix}0&2&0\\0&m&0\end{pmatrix} = 0. \tag{5.46}$$

Here the $3j$ symbols are zero because the triangle inequality is violated. Hence, there is no need for any further integration, all matrix elements of $\mathcal{H}_{dd}$ vanish in the $\{|n00; sIFm_F\rangle\}$ representation. Note that this holds not only for the diagonal matrix elements but also for the off-diagonal matrix elements of the T_2^m. Actually, along the same lines of reasoning also the coupling to s states with different principal quantum number vanishes. This shows that also in second order a dipole-dipole contribution to the hyperfine shift of s levels is absent. Although we set out to show that $\Delta E_{dd} = 0$ to first order in perturbation theory we found that this equation holds quite rigorously. Only when the spherical shape of the s orbitals is lost (e.g., in an external electric field) the dipole-dipole shift no longer vanishes.

5.3.3 Zero-field hyperfine shift in hydrogen-like atoms - the case $l > 0$

For electrons of non-zero orbital angular momentum the Fermi contact contribution is absent because any radial wavefunction with $l > 0$ is zero at the origin: $R_{nl}(0) = 0$ for $l > 0$. Unfortunately, this does not mean that we can forget about the contact interaction for all valence electrons in non-spherical orbital states. As it turns out, in many-electron atoms, polarization of the electron core by the valence electrons give rise to an induced Fermi contact interaction which can be so strong that it affects even the sign of $\mathcal{A}_{\mathrm{hfs}}$, in particular for alkali atoms in electronically excited states. The phenomenon of core polarization is discussed in Section 10.4.2. In hydrogen, core electrons are absent and the simple rule holds: for electrons with nonzero orbital angular momentum the contact interaction vanishes and $\mathcal{H}_{IL}$ and $\mathcal{H}_{dd}$ fully determine the hyperfine shift. For this reason, the results to be obtained in the current section apply to the hydrogenic case.

So let us focus on the contributions of $\mathcal{H}_{IL}$ and $\mathcal{H}_{dd}$ to the hyperfine shift. Rather than considering these contributions independently we calculate their sum,

$$\mathcal{H}_{IL}+\mathcal{H}_{dd}=\frac{\mu_0}{4\pi}\frac{\gamma_I|\gamma_e|}{r^3}[3\,(\mathbf{I}\cdot\hat{\mathbf{r}})\,(\mathbf{S}\cdot\hat{\mathbf{r}})+\mathbf{I}\cdot(\mathbf{L}-\mathbf{S})]. \tag{5.47}$$

Actually, we approximated $2g_L/g_e\simeq 1$, which is a good approximation since $(g_e-2)\,m_e/M\simeq 10^{-6}$. The shift follows with

$$\Delta E_{\mathrm{hfs}}(n\,^{2s+1}L_j)=\frac{\mu_0}{4\pi}\gamma_I|\gamma_e|\langle nlsjIFm_F|\frac{1}{r^3}[3\,(\mathbf{I}\cdot\hat{\mathbf{r}})\,(\mathbf{S}\cdot\hat{\mathbf{r}})+\mathbf{I}\cdot(\mathbf{L}-\mathbf{S})]|nlsjIFm_F\rangle. \tag{5.48}$$

To calculate the matrix elements we rewrite the equation in the form

$$\Delta E_{\mathrm{hfs}}(n\,^{2s+1}L_j)=\gamma_I\langle nlsjIFm_F|\mathbf{I}\cdot\mathbf{B}_J|nlsjIFm_F\rangle, \tag{5.49}$$

where

$$\mathbf{B}_J=\frac{\mu_0}{4\pi}\frac{|\gamma_e|}{r^3}[3\hat{\mathbf{r}}\,(\mathbf{S}\cdot\hat{\mathbf{r}})+(\mathbf{L}-\mathbf{S})] \tag{5.50}$$

may be interpreted as the effective magnetic field generated by the electron at the position of the nucleus. Since $\mathbf{B}_J$ is a vector operator acting in the space spanned by the spin-orbit basis $\{|nlsjm_j\rangle\}$, we can apply the Wigner-Eckart theorem to its components,

$$\langle nlsjm_j|B_{J_z}\,|nlsjm_j\rangle=\langle nlsj||B_J||nlsj\rangle\langle jm_j|J_z\,|jm_j\rangle \tag{5.51a}$$

$$\langle nlsj(m_j\pm1)|B_{J_\pm}\,|nlsjm_j\rangle=\langle nlsj||B_J||nlsj\rangle\langle j(m_j\pm1)|J_\pm\,|jm_j\rangle\,. \tag{5.51b}$$

Here we have written both the diagonal and the off-diagonal matrix elements of $\mathbf{B}_J$ to emphasize that the same reduced matrix element applies to both cases (reduced matrix elements do not depend on magnetic quantum numbers). This property gives us the freedom to determine $\langle nlsj||B_J||nlsj\rangle$ by considering only *diagonal* matrix elements (irrespective of the operator being diagonal or not). To determine $\langle nlsj||B_J||nlsj\rangle$ we choose to use the diagonal matrix elements of the operator $\mathbf{J}\cdot\mathbf{B}_J$,

$$\langle nlsjm_j|\mathbf{J}\cdot\mathbf{B}_J\,|nlsjm_j\rangle=\langle nlsj||B_J||nlsj\rangle\langle jm_j|\mathbf{J}^2\,|jm_j\rangle\,. \tag{5.52}$$

As shown in Problem 5.3 the evaluation of the matrix elements yields for hydrogen-like atoms ($s=\frac{1}{2}$)

$$\langle nlsj||B_J||nlsj\rangle=\frac{\mu_0}{4\pi}|\gamma_e|\langle nl||r^{-3}||nl\rangle\frac{l(l+1)}{j(j+1)}. \tag{5.53}$$

The expression for the hyperfine shift is obtained by returning to Eq. (5.48). We temporarily decompose the matrix elements for the hyperfine shift in the $\{|Im_Ijm_j\rangle\}$ basis. This enables us to apply Eqs. (5.51),

$$\begin{aligned}\Delta E_{\mathrm{hfs}}&=\gamma_I\sum_{m_I'm_j',m_Im_j}\langle Fm_F|jm_j'Im_I'\rangle\langle nlsjm_j'Im_I'|\mathbf{I}\cdot\mathbf{B}_J|nlsjm_jIm_I\rangle\langle jm_jIm_I|Fm_F\rangle\\&=\gamma_I\langle nlsj||B_J||nlsj\rangle\sum_{m_I'm_j',m_Im_j}\langle Fm_F|jm_j'Im_I'\rangle\langle jm_j'Im_I'|\mathbf{I}\cdot\mathbf{J}|jm_jIm_I\rangle\langle jm_jIm_I|Fm_F\rangle\\&=\gamma_I\langle nlsj||B_J||nlsj\rangle\langle nlsjIFm_F|\mathbf{I}\cdot\mathbf{J}|nlsjIFm_F\rangle.\end{aligned} \tag{5.54}$$

Substituting the reduced matrix element (5.53) we obtain

$$\Delta E_{\mathrm{hfs}}(n\,^{2s+1}L_j)=(\mathcal{A}_{\mathrm{hfs}}/\hbar^2)\langle jIFm_F|\mathbf{I}\cdot\mathbf{J}|jIFm_F\rangle, \tag{5.55}$$

where the coupling constant is given by

$$\mathcal{A}_{\rm hfs}(n\,^{2s+1}L_j) = \frac{\mu_0}{4\pi}\gamma_I|\gamma_e|\hbar^2\langle nl||r^{-3}||nl\rangle\frac{l(l+1)}{j(j+1)}. \tag{5.56}$$

Writing the radial matrix element in dimensionless form using $\rho = r/a$, with $a = (m_e/m_r)a_0$ being the atomic unit of length, we see that Eq. (5.56) coincides exactly with the expression for the hyperfine coupling constant announced in Eq. (5.35). Since $\mathbf{I}\cdot\mathbf{J}$ is diagonal in the $\{|jIFm_F\rangle\}$ basis the perturbation theory has been reduced to ordinary perturbation theory. This makes the analysis of the hyperfine structure into a straightforward exercise (as we demonstrate later in this chapter). This being said it should be remembered that the result is based on the assumption that the hyperfine coupling is much weaker than the spin-orbit interaction. If this is not satisfied the primary coupling of **L** and **S** into **J** cannot be justified. Furthermore, since the radius operator does *not* commute with the Schrödinger Hamiltonian we should be aware that states of different principal quantum number contribute in second order.

Problem 5.3. Show that for $s = \frac{1}{2}$ the reduced matrix element of the electronic field at the nucleus is given by

$$\langle nlsj||B_J||nlsj\rangle = \frac{\mu_0}{4\pi}|\gamma_e|\langle nl||r^{-3}||nl\rangle\frac{l(l+1)}{j(j+1)}.$$

Solution. Starting from Eq. (5.52) we have

$$\begin{aligned}\langle nlsj||B_J||nlsj\rangle &= \frac{\langle nlsjm_j|\mathbf{J}\cdot\mathbf{B}_J\,|nlsjm_j\rangle}{\langle jm_j|\mathbf{J}^2\,|jm_j\rangle}\\ &= \frac{\mu_0}{4\pi}\frac{|\gamma_e|}{j(j+1)\hbar^2}\langle nlsjm_j|\frac{1}{r^3}\{3\,(\mathbf{J}\cdot\hat{\mathbf{r}})\,(\mathbf{S}\cdot\hat{\mathbf{r}}) + \mathbf{J}\cdot(\mathbf{L}-\mathbf{S})\}|nlsjm_j\rangle.\end{aligned}$$

Noting that $\mathbf{J}\cdot\hat{\mathbf{r}} = \mathbf{S}\cdot\hat{\mathbf{r}}$ because $\mathbf{L}\cdot\hat{\mathbf{r}} = (\mathbf{r}\times\mathbf{p})\cdot\hat{\mathbf{r}} = 0$ we obtain, using the tensor decomposition (5.30) and retaining only the terms conserving m_j,

$$\begin{aligned}\langle nlsj||B_J||nlsj\rangle &= \frac{\mu_0}{4\pi}\frac{|\gamma_e|}{j(j+1)\hbar^2}\langle nlsjm_j|\frac{1}{r^3}\{[3\,(\mathbf{S}\cdot\hat{\mathbf{r}})^2 - \mathbf{S}^2] + \mathbf{L}^2\}|nlsjm_j\rangle\\ &= \frac{\mu_0}{4\pi}\frac{|\gamma_e|}{j(j+1)\hbar^2}\langle nlsjm_j|\frac{1}{r^3}\left\{\left[4S_z^2 - (S_-S_+ + S_+S_-)\right]Y_2^0(\hat{\mathbf{r}}) + \mathbf{L}^2\right\}|nlsjm_j\rangle\\ &= \frac{\mu_0}{4\pi}\frac{|\gamma_e|}{j(j+1)\hbar^2}\langle nlsjm_j|\frac{1}{r^3}\left\{(6S_z^2 - 2\mathbf{S}^2)Y_2^0(\hat{\mathbf{r}}) + \mathbf{L}^2\right\}|nlsjm_j\rangle.\end{aligned}$$

Decomposing the states $|nlsjm_j\rangle$ to the uncoupled basis $\{|lm_lsm_s\rangle\}$ we find, using $s = \frac{1}{2}$, that the electron-spin contribution vanishes

$$\langle lsjm_j|6S_z^2 - 2\mathbf{S}^2|lsjm_j\rangle = \sum_{m_lm_s}\langle lm_lsm_s|6S_z^2 - 2\mathbf{S}^2|lm_lsm_s\rangle\langle lm_lsm_s|lsjm_j\rangle^2 = 0.$$

Hence, factoring out the angular-independent part we obtain

$$\langle nlsj||B_J||nlsj\rangle = \frac{\mu_0}{4\pi}\frac{|\gamma_e|}{j(j+1)\hbar^2}\langle nl||r^{-3}||nl\rangle\langle lsjm_j|\mathbf{L}^2|lsjm_j\rangle,$$

which results in the requested expression when substituting $\langle lsjm_j|\mathbf{L}^2|lsjm_j\rangle = l(l+1)\hbar^2$. □

5.3.4 Magnetic hyperfine structure of hydrogen-like atoms

At this point we formulate the effective spin Hamiltonian for hydrogen-like atoms including magnetic hyperfine interaction (5.32),

$$\mathcal{H} = \mathcal{H}_0 + \mathcal{H}_r + (\zeta_{nl}/\hbar^2)\,\mathbf{L}\cdot\mathbf{S} + (\mathcal{A}_{\rm hfs}/\hbar^2)\,\mathbf{I}\cdot\mathbf{J}. \tag{5.57}$$

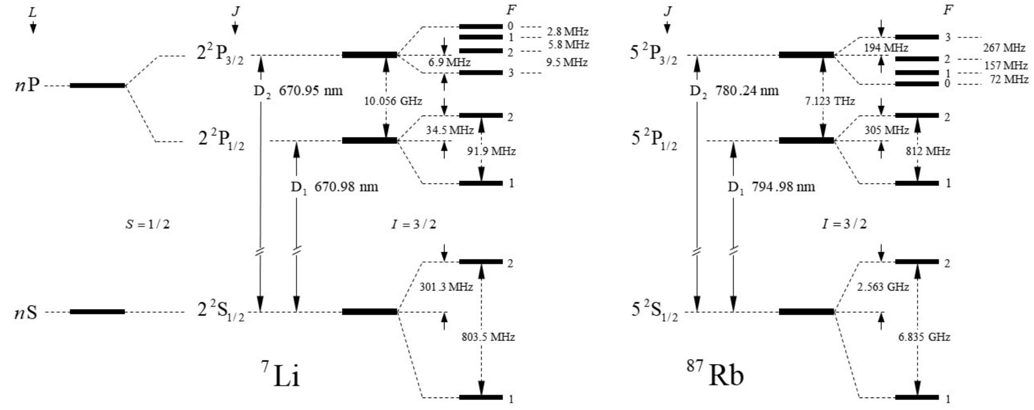

Figure 5.3: Zero-field hyperfine splittings of the lowest electronic states of ^{7}Li [11, 23] and ^{87}Rb [15, 124, 8]. As both species have the same nuclear spin $\left(I = \frac{3}{2}\right)$ the level diagrams are similar. Note that ^{87}Rb behaves like hydrogen whereas ^{7}Li does not (inversion of the hyperfine structure of the $^2P_{3/2}$ level; cf. Section 10.4.2).

This Hamiltonian suffices to calculate magnetic hyperfine shifts for hydrogen-like atoms of given n, l and j. For hydrogenic atoms the constants ζ_{nl} and $\mathcal{A}_{\rm hfs}$ can be calculated from first principles. For alkali-like atoms in their electronic ground state ζ_{nl} and $\mathcal{A}_{\rm hfs}$ can be regarded as empirical. For the excited states of alkali-like atoms they become non-hydrogen-like because the $\mathcal{A}_{\rm hfs}$ coefficients can become negative (cf. Section 10.4.2). As examples we show in Fig. 5.3 the hyperfine splitting of $n\,^2S_{1/2}$, $n\,^2P_{1/2}$ and $n\,^2P_{3/2}$ terms of ^{7}Li and ^{87}Rb.

To calculate the hyperfine splitting we use perturbation theory for degenerate levels. After splitting off the perturbation $\mathcal{H}' = \mathcal{H}_{\rm hfs}$ we calculate the energy shifts relative to the fine-structure levels $n\,^{2s+1}L_j$, characterized by n, l, s and j. As long as the hyperfine shifts remain small compared to the fine-structure splitting the quantum numbers n, l and j may be considered as "good quantum numbers to first-order in perturbation theory of a degenerate level" - see Eq. (H.56). The mathematical justification for this is that the second-order contribution to the energy shift (H.63) is negligibly small because the energy denominator of Eq. (H.63) is large. Physically, the quantum number j remains a good quantum number because the fine-structure coupling is much stronger than the hyperfine couplings. The fine-structure Hamiltonian (4.124) commutes with both $\mathbf{J}^2$ and $\mathbf{I}^2$ and because these operators also commute with $\mathbf{I}\cdot\mathbf{J}$ we know that j and I are good quantum number of the full Hamiltonian (5.57). Furthermore, as $\mathbf{F} = \mathbf{J} + \mathbf{I}$ and $\mathbf{F}^2 = \mathbf{J}^2 + \mathbf{I}^2 + 2\mathbf{I}\cdot\mathbf{J}$ we find that $\mathbf{F}^2$ and $F_z = J_z + I_z$ commute with both the fine-structure and the hyperfine Hamiltonian. Therefore, also F and m_F are good quantum numbers and $\mathcal{H}_{\rm hfs}$ is diagonal in the joint basis $\{|n(ls)jIFm_F\rangle\}$ of $\mathbf{L}\cdot\mathbf{S}$, $\mathbf{F}^2$ and F_z; i.e., for given values of n, l and j the quantum numbers F and m_F are good quantum numbers (s and I are always good quantum numbers in atomic physics because these represent intrinsic properties of the electron and the nucleus, respectively). The level shift caused by the hyperfine interaction depends on F and is then given by

$$\Delta E_F^{IJ}(n\,^{2s+1}L_j) = \left(\mathcal{A}_{\rm hfs}/\hbar^2\right)\langle jIFm_F|\mathbf{I}\cdot\mathbf{J}|jIFm_F\rangle, \tag{5.58}$$

where $\mathcal{A}_{\rm hfs}$ is the *hyperfine coupling constant* for given quantum numbers n, l and j.

5.3.5 Shift rules for the magnetic hyperfine coupling in zero field

Using the operator identity

$$\mathbf{I}\cdot\mathbf{J} = \tfrac{1}{2}(\mathbf{F}^2 - \mathbf{I}^2 - \mathbf{J}^2) \tag{5.59}$$

the *hyperfine shift* of the manifold with quantum number F takes the form

$$\Delta E_F^{IJ}(n\,^{2s+1}L_j) = \tfrac{1}{2}\mathcal{A}_{\rm hfs}\,[F(F+1) - j(j+1) - I(I+1)]\,. \tag{5.60}$$

Importantly, for negative $\mathcal{A}_{\rm hfs}$ the multiplet structure is *inverted.* As the form of Eq. (5.60) is identical to that of Eq. (4.126) derived for the fine-structure splitting this leads again to three shift rules of the type introduced in Section 4.5.2:

- the shift of the *stretched state* is given by

  $$\Delta E^{IJ}_{F_{\rm max}}(n\,^{2s+1}L_j) = \mathcal{A}_{\rm hfs}\, jI. \tag{5.61}$$

  Recall that the stretched state corresponds to the F manifold with the largest multiplicity, $F = F_{\rm max} = j + I$.

- the relative shift of two adjacent F manifolds follows an *interval rule* of the *Landé type*:

  $$\Delta W_F = \Delta E^{IJ}_F(n\,^{2s+1}L_j) - \Delta E^{IJ}_{F-1}(n\,^{2s+1}L_j) = \mathcal{A}_{\rm hfs} F_>, \tag{5.62}$$

  where $F_>$ is the quantum number of the manifold with the highest multiplicity of *adjacent pair*s, $F_> = max(F, F-1)$.

- the hyperfine manifolds satisfy the *center-of-gravity rule*:

  $$\frac{1}{(2I+1)\,(2j+1)} \sum_{F=|j-I|}^{j+I} (2F+1)\,\Delta E^{IJ}_F(n\,^{2s+1}L_j) = 0, \tag{5.63}$$

  where $(2I+1)\,(2j+1)$ is the degeneracy of the unperturbed $n\,^{2s+1}L_j$ level.

5.3.6 Magnetic hyperfine structure of hydrogenic atoms in zero field

For *hydrogenic* atoms the orbital parts in Eqs. (5.35) and (5.34) can be expressed analytically; using Eqs. (2.37) and (2.49c) we obtain

$$a_{\rm hfs} = \frac{\mu_0}{4\pi}\frac{8}{3}\frac{\gamma_I|\gamma_e|\hbar^2}{[(1+m_e/m_p)a_0]^3}\frac{Z^3}{n^3} \qquad (l=0) \tag{5.64a}$$

$$\mathcal{A}_{\rm hfs} = \frac{\mu_0}{4\pi}\frac{\gamma_I|\gamma_e|\hbar^2}{[(1+m_e/m_p)a_0]^3}\frac{Z^3}{n^3}\frac{1}{j(j+1)(l+{}^1\!/_2)} \qquad (l>0). \tag{5.64b}$$

For all *hydrogen-like* atoms in s levels the hyperfine states are *spin doublets* $\left(j=\frac{1}{2}\right)$. In such systems coupling of the nuclear spin $\mathbf{I}$ to the total electronic angular momentum $\mathbf{J}$ can result in only two values of total angular momentum: $F = I + \frac{1}{2}$ (parallel coupling) and $F' = I - \frac{1}{2}$ (anti-parallel coupling). For these two cases we have

$$\Delta E^{IJ}_F(n\,^{2s+1}L_{1/2}) = \begin{cases} +\frac{1}{2}a_{\rm hfs}I & \left(F = I+\frac{1}{2}\right) \\ -\frac{1}{2}a_{\rm hfs}(I+1) & \left(F = I-\frac{1}{2}\right) \end{cases}\Bigg\}\ \text{for } F>0 \\ \quad 0 \qquad\qquad\qquad\qquad\qquad \text{for } F=0. \tag{5.65}$$

For $\gamma_I > 0$ ($\gamma_I < 0$) the state with the highest multiplicity has the highest (lowest) energy.

5.3.6.1 Hydrogen in its electronic ground state $1\,^2S_{1/2}$

The electronic ground state of atomic hydrogen is the $1\,^2S_{1/2}$ state. With nuclear spin $I = \frac{1}{2}$ the hyperfine levels correspond to $F = 0, 1$. Starting from Eq. (5.64) the hyperfine splitting may be rewritten in terms of fundamental constants,

$$\Delta\nu_{\rm hfs} = a_{\rm hfs}/h = \tfrac{4}{3}g_p(1+a_e)\alpha^4\frac{m_e}{m_p}\frac{m_ec^2/h}{(1+m_e/m_p)^3}, \tag{5.66}$$

where $a_e = (g_e - 2)/2 = 1.159\,652\,180\,91(26) \times 10^{-3}$ is the electron anomaly (see Section 4.3.6), $g_p = 5.585\,694\,702(17)$ the proton g factor, $\alpha = 7.297\,352\,5664(17) \times 10^{-3}$ the fine-structure constant, $m_e = 9.109\,383\,56(11) \times 10^{-31}$ kg the electron rest mass $m_e/m_p = 5.446\,170\,213\,52(52) \times 10^{-4}$ the electron-proton mass ratio and $c = 299\,792\,458$ m s^{-1} the defined value for the speed of light in vacuum. With the quoted values for the fundamental constants we calculate $\Delta\nu_{\mathrm{hfs}} \simeq 1.420\,49$ GHz. The experimental value is [118]

$$\Delta\nu_{\mathrm{hfs}} = 1\,420\,405\,751.770(3)\ \mathrm{Hz}. \tag{5.67}$$

Remarkably, the simple theory presented here already gives agreement at the level $1 : 10^4$. With the most advanced theories one, possibly two additional digits can be accounted for. When not accounting for the electron anomaly agreement is worse, about $1 : 10^3$. Historically, this discrepancy gave rise to the suggestion of the existence of the electron anomaly and its relevance in relation to quantum electrodynamics [21]. The experimental precision became possible with the development of the *hydrogen maser*, the first example of an *atomic clock* [89]. The *precision* of the hydrogen maser is better than the actual *accuracy*, which is limited by collisions of the hydrogen atoms in the clock. Beware that the hyperfine structure of *deuterium* (nuclear spin $I = 1$) is complicated by the presence of a nuclear electric quadrupole moment (see Chapter 6).

Hyperfine transitions in ground state hydrogen are also well-known from radio astronomy as they give rise to electromagnetic radiation at 1.420 GHz, (wavelength 21 cm). This wavelength is not absorbed in the earth atmosphere. The 21 cm radiation of cosmic origin is famous because it was used to reveal, for the first time, the spiral structure of our galaxy [117].

5.3.7 Transition dipole moments in the presence of hyperfine coupling

In the presence of hyperfine coupling m_j is no longer a good quantum number and this has consequences for the calculation of the transition-dipole moment of the electric-dipole operator. The eigenstates of the Hamiltonian are given by the basis $|nlsjIFM\rangle$ and the transition dipole is of the form

$$\mathbf{D}_{eg} = D_{eg}\hat{\mathbf{u}}_q^*, \tag{5.68}$$

where $e = |n'l's'j'I'F'M'\rangle$, $g = |nlsjIFM\rangle$ and

$$D_{eg} = -ea\,\langle n'l's'j'I'F'M'|\,\sqrt{4\pi/3}\rho Y_1^q(\hat{\mathbf{r}})\,|nlsjIFM\rangle \tag{5.69}$$

is the *transition dipole moment*, with $q = M' - M$. Starting again with the Wigner-Eckart theorem we have

$$D_{eg} = -ea(-1)^{F'-M'}\langle n'l's'j'I'F'||\sqrt{4\pi/3}\rho Y_1(\hat{\mathbf{r}})||nlsjIF\rangle \begin{pmatrix} F' & 1 & F \\ -M' & q & M \end{pmatrix}. \tag{5.70}$$

In this case the reduced matrix element $\langle n'l's'j'I'F'||\sqrt{4\pi/3}\rho Y_1(\hat{\mathbf{r}})||nlsjIF\rangle$ can be further reduced. Therefore, we turn to the reduction formula (K.62),

$$\begin{aligned}\langle n'l's'j'I'F'||\sqrt{4\pi/3}\rho Y_1(\hat{\mathbf{r}})||nlsjIF\rangle &= (-1)^{F+j'+I+1}\delta_{I,I'}\times \\ &\times \langle n'l's'j'||\sqrt{4\pi/3}\rho Y_1(\hat{\mathbf{r}})||nlsj\rangle\sqrt{(2F+1)(2F'+1)}\begin{Bmatrix} j' & F' & I \\ F & j & 1 \end{Bmatrix}.\end{aligned} \tag{5.71}$$

Substituting Eq. (4.156) this becomes

$$\begin{aligned}\langle n'l's'j'I'F'||\sqrt{4\pi/3}\rho Y_1(\hat{\mathbf{r}})||nlsjIF\rangle &= (-1)^{F+j'+I+j+s+\max(l,l')}\mathcal{R}_{n'l',nl}\delta_{l',l\pm1}\delta_{s,s'}\delta_{I,I'} \\ &\times \sqrt{\max(l,l')(2j+1)(2j'+1)(2F+1)(2F'+1)}\begin{Bmatrix} l' & j' & s \\ j & l & 1 \end{Bmatrix}\begin{Bmatrix} j' & F' & I \\ F & j & 1 \end{Bmatrix}.\end{aligned} \tag{5.72}$$

Writing the transition dipole moment in the form

$$D_{eg} = -ea\mathcal{R}_{n'l',nl}\mathcal{A}^{l'ls}_{j'IF'M',jIFM}\delta_{l',l\pm1}\delta_{s,s'}\delta_{I,I'}, \tag{5.73}$$

we find for the angular contribution (after reordering the $3j$ symbol)

$$\begin{aligned}\mathcal{A}^{l'ls}_{j'IF'M',jIFM} &= (-1)^{-M'+j'+j+I+s+1+\max(l,l')} \\ &\times \sqrt{\max(l,l')\,(2j+1)\,(2j'+1)\,(2F+1)\,(2F'+1)} \begin{Bmatrix} l' & j' & s \\ j & l & 1 \end{Bmatrix} \begin{Bmatrix} j' & F' & I \\ F & j & 1 \end{Bmatrix} \begin{pmatrix} F & 1 & F' \\ M & q & -M' \end{pmatrix}. \end{aligned} \tag{5.74}$$

The *selection rules* for hyperfine transitions (determined by the $3j$ symbol) are:

$$\Delta M = 0, \pm1 \quad \text{for } \pi, \sigma^{\pm} - \text{transitions} \tag{5.75a}$$

$$\Delta F = 0, \pm1 \quad (\text{excluding } F = 0 \leftrightarrow F' = 0) \tag{5.75b}$$

These selection rules come on top of those of the fine structure

$$\Delta j = 0, \pm1 \quad (\text{excluding } j = 0 \leftrightarrow j' = 0) \tag{5.76a}$$

$$\Delta l = \pm1 \qquad \Delta s = 0 \qquad \Delta I = 0. \tag{5.76b}$$

In addition also the triangular inequalities $\Delta(l,s,j)$, $\Delta(l'sj')$, $\Delta(I,j,F)$ and $\Delta(I,j',F')$ must be satisfied. Note that the cases $F = F' = 0$ and $j = j' = 0$ are excluded because the triangular inequalities $\Delta(F,F',1)$ and $\Delta(j,j',1)$ cannot be satisfied.

5.3.7.1 Example: sp transitions in hydrogen-like atoms ($s = 1/2$) with $I = 3/2$

The result for the angular contributions to the strength of $p \to s$ transitions between two fine-structure levels ($j' \to j$) and in the presence of hyperfine coupling ($F' = 4,3,2,1,0 \to F = 2,1$) depends, for given I, F', on F and $M' \equiv M_{F'}$. Summing over the magnetic quantum numbers of the $F = 1,2$ levels (which are the only two s levels) we obtain

$$\sum_{F=1}^{2}\sum_{M=-F}^{F} \mathcal{A}^2_{\frac{3}{2}IF'M',\frac{1}{2}IFM} = \tfrac{1}{3}. \tag{5.77}$$

Note that (for given I) this sum is *independent* of F' and M'; i.e., the sum is same for all values of the magnetic quantum number of the p level. This is illustrated in Fig. 5.4. The sum rule can be understood from the physical point of view by considering electric-dipole transitions. Since the electric-dipole operator does not couple to spin degrees of freedom (it acts in a different sector of Hilbert space), the spins cannot affect the total electric dipole transition rate. It only distributes the rate over the available final states in the form of σ_+, σ_- and π contributions. For transitions from the $F' = 2$ level 50 % passes through the $F' = 2 \to F = 2$ channel and 50 % passes through the $F' = 2 \to F = 1$ channel. Likewise, for transitions from the $F' = 1$ level 1/6 passes through the $F' = 1 \to F = 2$ channel and 5/6 passes through the $F' = 1 \to F = 1$ channel.

5.4 Hyperfine structure in an applied magnetic field

Adding to the Hamiltonian (5.57) the Zeeman Hamiltonian (5.23) we obtain the effective Hamiltonian for the hyperfine-structure of hydrogen-like atoms in an externally applied magnetic field,

$$\mathcal{H} = \mathcal{H}_0 + \mathcal{H}_r + (\zeta_{nl}/\hbar^2)\,\mathbf{L}\cdot\mathbf{S} + (\mathcal{A}_{\text{hfs}}/\hbar^2)\,\mathbf{I}\cdot\mathbf{J} - (\boldsymbol{\mu}_L + \boldsymbol{\mu}_s + \boldsymbol{\mu}_I)\cdot\mathbf{B}, \tag{5.78}$$

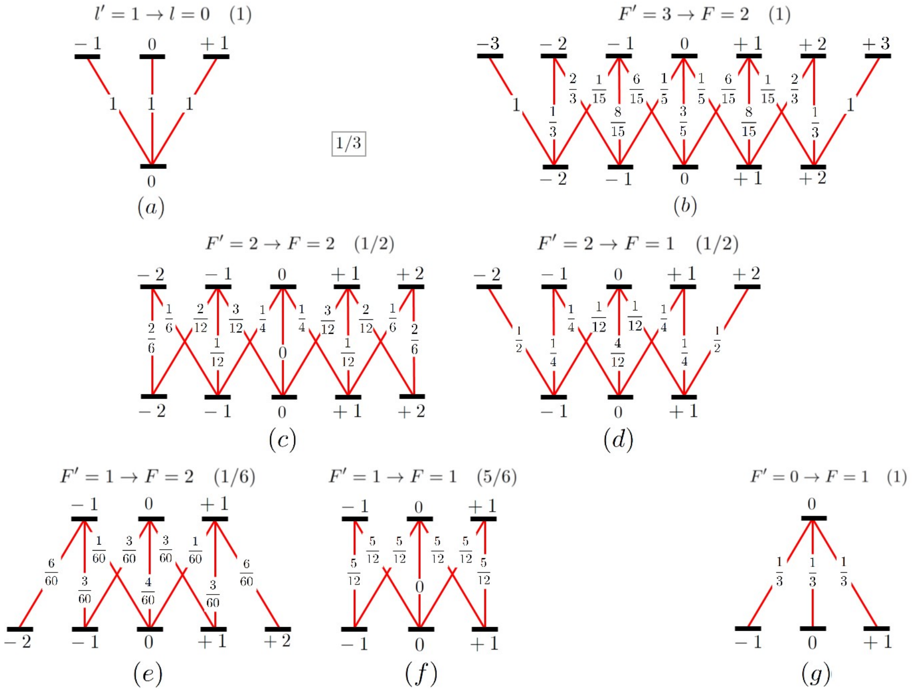

Figure 5.4: The angular contributions to the transition strength between two angular momentum levels (l' and l) is independent of the presence (or absence) of hyperfine structure. This is illustrated for $p \to s$ transitions in hydrogen-like atoms with both fine structure and hyperfine structure (the example of ^{87}Rb): (a) in principal structure (see also Figs. 2.4 and 4.15); (b) from $F' = 3$ level; (c) and (d) from $F' = 2$ level; (e) and (f) from $F' = 1$ level and (g) from $F' = 0$ level. Note that the sum of the probabilities starting from any of the $M_{F'}$ levels, always yields the same value (unity, not counting the common prefactor 1/3).

which can be written in the form

$$\mathcal{H} = \mathcal{H}_{\mathrm{fs}} + (\mathcal{A}_{\mathrm{hfs}}/\hbar^2)\,\mathbf{I}\cdot\mathbf{J} + [g_J(e/2m_e)\mathbf{J} - g_I(e/2m_p)\mathbf{I}]\cdot\mathbf{B}\ , \tag{5.79}$$

where $\mathcal{H}_{\mathrm{fs}}$ represents the zero field fine-structure Hamiltonian (see Section 4.5.1),

$$\mathcal{H}_{\mathrm{fs}} = \mathcal{H}_0 + \mathcal{H}_r + (\zeta_{nl}/\hbar^2)\,\mathbf{L}\cdot\mathbf{S}. \tag{5.80}$$

Eq. (5.79) is a suitable Hamiltonian for use in "first-order in perturbation theory of a degenerate level" as long as n, l and j are good quantum numbers; i.e., for magnetic fields much smaller than the fine-structure crossover field ($B \ll |B_{\mathrm{fs}}|$). Choosing the quantization axis (z axis) along the magnetic field direction Eq. (5.79) can be written in the form

$$\mathcal{H} = \mathcal{H}_{\mathrm{fs}} + (\mathcal{A}_{\mathrm{hfs}}/\hbar^2)\,\mathbf{I}\cdot\mathbf{J} + (g_J\mu_B J_z - g_I\mu_N I_z)B/\hbar. \tag{5.81}$$

In analogy with Eq. (4.164) we write the Hamiltonian in the form $\mathcal{H} = \mathcal{H}_{\mathrm{fs}} + \mathcal{H}'$, where

$$\mathcal{H}' = \mathcal{H}_{\mathrm{hfs}} + \mathcal{H}_Z, \tag{5.82}$$

is the perturbation to be considered, with

$$\mathcal{H}_{\mathrm{hfs}} = (\mathcal{A}_{\mathrm{hfs}}/\hbar^2)\,\mathbf{I}\cdot\mathbf{J} \quad \text{and} \quad \mathcal{H}_Z = (g_J\mu_B J_z - g_I\mu_N I_z)B/\hbar \tag{5.83}$$

representing the hyperfine coupling and the (electronic plus nuclear) Zeeman terms, respectively. Although both $\mathbf{I}\cdot\mathbf{J}$ and $\mathcal{H}_Z$ commute separately with $\mathcal{H}_{\mathrm{fs}}$, mutually they do *not* commute. Physically, there is competition between the mutual coupling of **J** and **I** and the coupling of **J** and **I** individually with the external **B** field. In low fields the hyperfine coupling is dominant, whereas in the high field limit it may be neglected (better: gives a field-independent contribution). This is called the *Back-Goudsmit effect* [6], the exact analogue of the *Paschen-Back effect* [78] in the atomic fine structure in which **L** and **S** decouple (see also [79]). As the fine-structure coupling is stronger than the hyperfine coupling, the Paschen-Back decoupling typically takes place at higher fields than the hyperfine decoupling. In intermediate fields the perturbation $\mathcal{H}'$ is neither diagonal in the $\{|nlsjIFm_F\rangle\}$ (*coupled*) representation nor in the $\{|nlsjm_jIm_I\rangle\}$ (*uncoupled*) representation and we have to solve a secular equation of the type (I.24) just as in the case of the atomic fine structure (Section 4.7).

5.4.1 Matrix elements in the uncoupled basis

To solve the secular equation in the *uncoupled* representation we use the inner product rule (3.159b) to write the perturbation in the form

$$\mathcal{H}' = (a_{\mathrm{hfs}}/\hbar^2)\left[I_zJ_z + \tfrac{1}{2}\left(I_+J_- + I_-J_+\right)\right] + (g_J\mu_BJ_z - g_I\mu_NI_z)B/\hbar. \tag{5.84}$$

Note that this Hamiltonian conserves the total angular momentum along the z axis; i.e., $m_j + m_I = m_F$ is a good quantum number (F_z commutes with the Hamiltonian) for all values of the magnetic field. The diagonal matrix elements are for a given value of m_F

$$\begin{aligned}\langle nIm_Ijm_j|\mathcal{H}'|nIm_Ijm_j\rangle &= \langle nI\left(m_F - m_j\right)jm_j|\mathcal{H}'|nI\left(m_F - m_j\right)jm_j\rangle \\ &= a_{\mathrm{hfs}}\left(m_F - m_j\right)m_j - g_I\mu_Nm_FB + \left(g_J\mu_B + g_I\mu_N\right)m_jB \\ &\equiv \langle m_Fm_j|\mathcal{H}'\,|m_Fm_j\rangle \equiv \mathcal{H}'_{m_Fm_jm_j},\end{aligned} \tag{5.85}$$

with $m_e/m_p = \mu_N/\mu_B$ being the electron-proton mass ratio. Note that in these matrix elements the states $\{|nlsjm_jIm_I\rangle\}$ share fixed values for the quantum numbers n, l, s, j and I; only the values of m_j and m_I vary. Using the relation $m_I = m_F - m_j$ we gave preference to specification of m_F and m_j rather than m_j and m_I. Turning to the shorthand notation $|nlsjm_jIm_I\rangle \to |m_Fm_j\rangle$ the matrix elements take the form $(m_Fm_j'|\mathcal{H}'|m_Fm_j\rangle$. Since m_F is conserved by $\mathcal{H}'$ the notation can be condensed to $\mathcal{H}'_{m_Fm_jm_j}$. The terms $\frac{1}{2}\left(a_{\mathrm{hfs}}/\hbar^2\right)\left(I_+J_- + I_-J_+\right)$ give rise to off-diagonal elements and are calculated using the shift operators (1.59) and the conservation of m_F,

$$\begin{aligned}\langle nIm_I'jm_j'|\mathcal{H}'|nIm_Ijm_j\rangle &= \langle nI\left(m_F - m_j \pm 1\right)j\left(m_j \mp 1\right)|\mathcal{H}'|nI\left(m_F - m_j\right)jm_j\rangle \\ &= \tfrac{1}{2}a_{\mathrm{hfs}}\sqrt{I\left(I+1\right) - \left(m_F - m_j\right)\left(m_F - m_j \pm 1\right)}\sqrt{j\left(j+1\right) - m_j(m_j \mp 1)} \\ &\equiv \langle(m\left(m_j \mp 1\right)|\mathcal{H}'|m_Fm_j\rangle \equiv \mathcal{H}'_{m_F(m_j\mp1)m_j}.\end{aligned} \tag{5.86}$$

Hence, the perturbation couples states differing in m_j such that $\Delta m_j = \pm 1$ while $m_I + m_j = m_F$ remains conserved. For the coupled basis $\{|nIjFm_F\rangle\}$ this implies that the perturbation couples states differing in F such that $\Delta F = \pm 1$ while m_F remains conserved. In the description of the field dependence preference will be given to expressing coupled states in terms of uncoupled states, rather than the other way around, because in the uncoupled representation the expressions for the limiting cases of low and high field remain intuitively transparent. In the coupled representation the latter is only the case for the low-field limit.

5.4.2 Hydrogen-like atoms with $j = 1/2$

For hydrogen-like atoms in states with $j = \frac{1}{2}$ and $F = I \pm \frac{1}{2}$ the solution of the secular equation can be obtained analytically for arbitrary magnetic field. This case applies to the electronic ground states of hydrogen ($1\,^2S_{1/2}$) and all the alkali atoms ($n\,^2S_{1/2}$ with $n = 2 - 7$). As we are dealing with s orbitals the orbital magnetic moment is zero and g_J coincides with the free-electron g value,

$g_J = g_e$. The ${}^2S_{1/2}$ states behave like the *spin doublets* discussed in Section 4.7.3. The hyperfine shifts in zero field were obtained in Section 5.3.4,

$$\Delta E^{I1/2}_{I\pm 1/2}(n\,{}^2S_{1/2}) = \begin{cases} +\tfrac{1}{2}a_{\mathrm{hfs}}I & \text{for } F = I + \tfrac{1}{2} \\ -\tfrac{1}{2}a_{\mathrm{hfs}}\,(I+1) & \text{for } F = I - \tfrac{1}{2}. \end{cases} \quad \text{for } F > 0. \tag{5.87}$$

However, unlike the spin doublets discussed in Section 4.7.3 the state with the lowest multiplicity is *not necessarily* the state with the lowest energy but this depends on the sign of a_{hfs} and therefore on the sign of the nuclear gyromagnetic ratio γ_I. For $\gamma_I > 0$ ($\gamma_I < 0$) the state of lowest multiplicity has the lowest (highest) energy, as illustrated in Fig. 5.5. In the absence of nuclear spin ($I = 0$) this shift is absent. For $I > 0$ the perturbation matrix takes the form

$$\mathcal{H}' = \begin{pmatrix} \mathcal{H}'_{M\uparrow\uparrow} & 0 & 0 & \cdots & 0 & 0 & 0 \\ 0 & \mathcal{H}'_{(M-1)\uparrow\uparrow} & \mathcal{H}'_{(M-1)\uparrow\downarrow} & \cdots & 0 & 0 & 0 \\ 0 & \mathcal{H}'_{(M-1)\downarrow\uparrow} & \mathcal{H}'_{(M-1)\downarrow\downarrow} & \cdots & 0 & 0 & 0 \\ \vdots & \vdots & \vdots & & \vdots & \vdots & \vdots \\ 0 & 0 & 0 & \cdots & \mathcal{H}'_{(-M+1)\uparrow\uparrow} & \mathcal{H}'_{(-M+1)\uparrow\downarrow} & 0 \\ 0 & 0 & 0 & \cdots & \mathcal{H}'_{(-M+1)\downarrow\uparrow} & \mathcal{H}'_{(-M+1)\downarrow\downarrow} & 0 \\ 0 & 0 & 0 & \cdots & 0 & 0 & \mathcal{H}'_{-M\downarrow\downarrow} \end{pmatrix}, \tag{5.88}$$

where $M \equiv I + \frac{1}{2}$ and $\uparrow$ is the short hand notation for $m_j = \frac{1}{2}$ (and $\downarrow$ for $m_j = -\frac{1}{2}$). The quantum number m_F varies within the range $-M \leq m_F \leq M$. Note that the matrix is a $d \times d$ matrix, where $d = (2I+1)(2j+1)$ is the dimension of the angular momentum subspace in which $\mathbf{I}$ and $\mathbf{J}$ operate. The secular equation is of the asymmetric type (cf. Appendix H.3) and factorizes into a product of two (1×1) and $I + 1$ (2×2) determinants, each characterized by its value of $m_F = m_j + m_I$. With the aid of Eqs. (5.85) and (5.86) the matrix elements are found to be

$$\mathcal{H}'_{m_F\uparrow\uparrow} = +\tfrac{1}{2}a_{\mathrm{hfs}}\left(m_F - \tfrac{1}{2}\right) - g_I\mu_N m_F B + \tfrac{1}{2}\mu_+ B \tag{5.89a}$$

$$\mathcal{H}'_{m_F\downarrow\downarrow} = -\tfrac{1}{2}a_{\mathrm{hfs}}\left(m_F + \tfrac{1}{2}\right) - g_I\mu_N m_F B - \tfrac{1}{2}\mu_+ B \tag{5.89b}$$

$$\mathcal{H}'_{m_F\downarrow\uparrow} = +\tfrac{1}{2}a_{\mathrm{hfs}}(I + \tfrac{1}{2})(1 - \tilde{m}_F^2)^{1/2} = \mathcal{H}'_{m_F\uparrow\downarrow}, \tag{5.89c}$$

where

$$\mu_\pm \equiv g_J\mu_B \pm g_I\mu_N \tag{5.90a}$$

$$\tilde{m}_F \equiv m_F/(I + \tfrac{1}{2}) \quad \text{with} \quad -1 \leq \tilde{m}_F \leq 1. \tag{5.90b}$$

Note that the symbol μ_- is not relevant in the present context. It is included in the definition (5.90a) for future convenience.

5.4.2.1 Pure states

For $m_F = \pm(I + \frac{1}{2})$ the coupling term vanishes, $\mathcal{H}'_{m_F\downarrow\uparrow} = 0$. These cases correspond to the *stretched states*,

$$|F_{\max}, \pm(I + \tfrac{1}{2})\rangle = \left|s, \pm\tfrac{1}{2}; I, \pm I\right\rangle. \tag{5.91}$$

The corresponding energies are

$$\varepsilon_\pm = \tfrac{1}{2}a_{\mathrm{hfs}}I \mp g_I\mu_N(I + \tfrac{1}{2})B \pm \tfrac{1}{2}\mu_+ B \qquad \text{for } m_F = \pm(I + \tfrac{1}{2}). \tag{5.92}$$

Note that the last term dominates the field dependence.

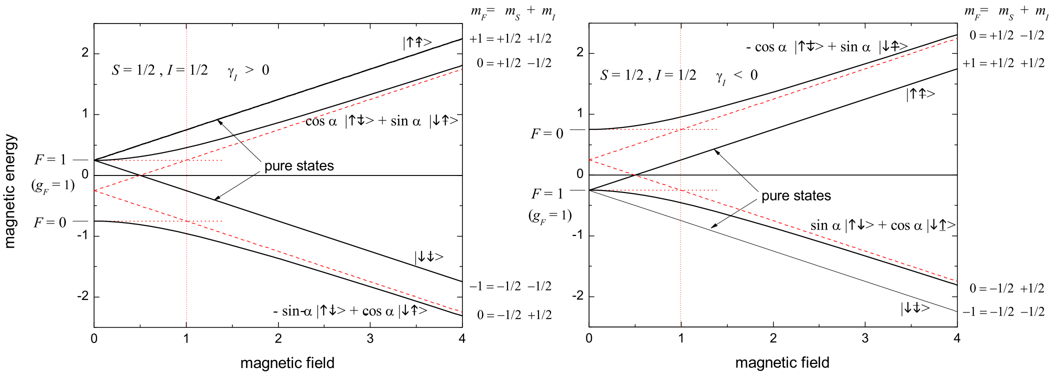

Figure 5.5: Magnetic energy versus magnetic field in units of the hyperfine field $|B_{\rm hfs}|$. Left: positive hyperfine shift. Right: negative hyperfine shift. We adopt the convention $\sin\alpha \to 0$ for $B \gg |B_{\rm hfs}|$. The dashed (dotted) lines correspond to the high-field (low-field) tangents of the energy curves.

5.4.2.2 Mixed states

The other states ($-1 < \tilde{m}_F < 1$) are *mixed states* because they involve linear combinations of the uncoupled basis states. Depending on the sign of γ_I we write this linear combination in the form (see Fig. 5.5)

$$\gamma_I > 0 \qquad \begin{cases} |F_{\rm max}, m_F\rangle = +\cos\alpha |\uparrow, I, \left(m_F - \tfrac{1}{2}\right)\rangle + \sin\alpha |\downarrow, I, \left(m_F + \tfrac{1}{2}\right)\rangle \\ |F_{\rm min}\,, m_F\rangle = -\sin\alpha |\uparrow, I, \left(m_F - \tfrac{1}{2}\right)\rangle + \cos\alpha |\downarrow, I, \left(m_F + \tfrac{1}{2}\right)\rangle \end{cases} \tag{5.93a}$$

$$\gamma_I < 0 \qquad \begin{cases} |F_{\rm min}\,, m_F\rangle = -\cos\alpha |\uparrow, I, \left(m_F - \tfrac{1}{2}\right)\rangle + \sin\alpha |\downarrow, I, \left(m_F + \tfrac{1}{2}\right)\rangle \\ |F_{\rm max}, m_F\rangle = +\sin\alpha |\uparrow, I, \left(m_F - \tfrac{1}{2}\right)\rangle + \cos\alpha |\downarrow, I, \left(m_F + \tfrac{1}{2}\right)\rangle. \end{cases} \tag{5.93b}$$

In both cases the states $|F_{\rm max}, m_F\rangle$ and $|F_{\rm min}, m_F\rangle$ are seen to form an orthonormal pair. The difference in notation between the two cases is introduced solely to improve the readability of the expressions (5.93a) and (5.93b); it implies that $\sin\alpha \simeq \alpha \to 0$ in the limit of high magnetic fields, irrespective of the value of γ_I. This notation offers the convenience of indicating which uncoupled state can be neglected in high magnetic fields. From the limit $B \to 0$ we know that for $\gamma_I > 0$ the *upper* branch of the spin doublets must correspond to the $F_{\rm max}$ manifold; likewise, for $\gamma_I < 0$ the *lower* branch of the spin doublets must correspond to the $F_{\rm min}$. In the $B \to 0$ limit the Zeeman energy vanishes and F becomes a good quantum number $\left(F_{\rm max} \to F = I + \tfrac{1}{2},\ F_{\rm min} \to F = I - \tfrac{1}{2}\right)$ and the Eqs. (5.93a) and (5.93b) take the form of a Clebsch-Gordan decomposition - compare with Eq. (J.45). The phase factors are chosen in accordance with the *Condon and Shortley phase convention*, where the phase factors are unity for the branch of maximal F and $m_F = F$ (parallel coupling).

The energies of the mixed states are given by solutions of the secular equation for given value of m_F,

$$W_\pm = \tfrac{1}{2}\left(\mathcal{H}'_{m_F\uparrow\uparrow} + \mathcal{H}'_{m_F\downarrow\downarrow}\right) \pm \tfrac{1}{2}\sqrt{(\mathcal{H}'_{m_F\uparrow\uparrow} - \mathcal{H}'_{m_F\downarrow\downarrow})^2 + 4|\mathcal{H}'_{m_F\downarrow\uparrow}|^2}. \tag{5.94}$$

This equation can be expressed in the form of the *Breit-Rabi formula* [22],

$$\varepsilon_\pm(m_F) = -g_I\mu_N m_F B - \tfrac{1}{4}a_{\rm hfs} \pm \tfrac{1}{2}|a_{\rm hfs}|(I + \tfrac{1}{2})\sqrt{1 + 2\tilde{m}_F B/B_{\rm hfs} + (B/B_{\rm hfs})^2}. \tag{5.95}$$

Since $|\tilde{m}_F| < 1$, the discriminant is always positive. The modulus $|a_{\rm hfs}|$ assures that ε_+ always represents the largest of the two roots ($\varepsilon_+ \geq \varepsilon_-$); i.e., corresponds the upper branch of the hyperfine doublet. Eq. (5.95) expresses the magnetic field dependence of the hyperfine shift for hydrogen-like atoms with $j=\frac{1}{2}$ and for given values of F and $m_F = m_I + m_j \neq \pm(I+\frac{1}{2})$. The characteristic field

$$B_{\rm hfs} = a_{\rm hfs}(I+\tfrac{1}{2})/\mu_+ \tag{5.96}$$

is called the *hyperfine field* with μ_+ defined by Eq. (5.90a); $B_{\rm hfs}$ is an effective *internal magnetic field* which can be positive or negative depending on the sign of $a_{\rm hfs}$. Its absolute value, $|B_{\rm hfs}|$, is the *hyperfine crossover field* and corresponds to the intersection point of the low-field and high-field asymptotic expressions for the hyperfine energy. For the ground state of atomic hydrogen the crossover field is $B_{\rm hfs} \simeq 50.7$ mT, much smaller than the fine-structure crossover field estimated in Section 4.7.3. Thus, in many cases of practical interest the high-field limit is reached for the hyperfine coupling when the atom is still in the low-field limit for the fine structure ($|B_{\rm hfs}| \ll |B_{\rm fs}|$). If this comfortable separation of energy scales is absent one has to diagonalize the combined secular equations for the fine structure and the hyperfine structure, which is already a task for which computers are best suited. Actually, some will say: why bother about analytic solutions at all when computer diagonalizations are swift and flawless even in complicated cases! In this respect it is good to be aware that the proper assignment of the basis vectors and a consistent phase convention remains an issue for which analytic understanding remains indispensable.

To obtain the eigenstates corresponding to the energies ε_+ and ε_- we have to determine the coefficients in Eqs. (5.93). This is done by the procedure described in Appendix H.3. The amplitudes of the coefficients, $A_+ \equiv \cos\alpha$ and $A_- \equiv \sin\alpha$, follow by substitution of the matrix elements (5.89a)-(5.89c) into Eq. (G.51),

$$\left.\begin{array}{l}\gamma_I > 0 : A_\pm^2 \\ \gamma_I < 0 : A_\mp^2\end{array}\right\} = \frac{1-\tilde{m}_F^2}{\left(\tilde{m}_F + B/B_{\rm hfs} \mp \sqrt{1+2\tilde{m}_F B/B_{\rm hfs} + (B/B_{\rm hfs})^2}\right)^2 + 1 - \tilde{m}_F^2}. \tag{5.97}$$

Clock states ($m_F=0$)**:** A special class of mixed hyperfine states are *clock states*, states with $m_F=0$. Near zero field these states are insensitive for small variations in magnetic field which explains their importance for precision time and frequency measurements. For $m_F=0$ the Breit-Rabi formula takes the form

$$\varepsilon_\pm(0) = -\tfrac{1}{4}a_{\rm hfs} \pm \tfrac{1}{2}|a_{\rm hfs}|(I+\tfrac{1}{2})\sqrt{1+(B/B_{\rm hfs})^2}. \tag{5.98}$$

The amplitudes are given by

$$A_\pm^2 = \left(B/B_{\rm hfs} \mp \sqrt{1+(B/B_{\rm hfs})^2}\right)^{-2}. \tag{5.99}$$

High-field limit ($B \gg |B_{\rm hfs}|$)**:** In high magnetic fields we can expand the Breit-Rabi formula (5.95) in powers of $B_{\rm hfs}/B$. Retaining only the terms up to first order in $B_{\rm hfs}/B$ we obtain

$$\varepsilon_\pm(m_F) = -g_I\mu_N m_F B - \tfrac{1}{4}a_{\rm hfs} \pm \tfrac{1}{2}\mu_+ B(1+\tilde{m}_F B_{\rm hfs}/B). \tag{5.100}$$

This expression corresponds to the *high-field asymptotes* indicated by the dashed lines in Fig. 5.5. Using a similar expansion Eq. (5.97) takes the form

$$A_-^2 = \sin^2\alpha \simeq \tfrac{1}{4}(1-\tilde{m}_F^2)(B/B_{\rm hfs})^2 \to 0. \tag{5.101}$$

This is an example of *weak coupling (strong asymmetry)* as defined in Appendix G.3.4.

Low-field limit ($B \ll |B_{\rm hfs}|$)**:** For low magnetic fields we can expand Eq. (5.95) in powers of $B/B_{\rm hfs}$. Retaining the terms up to second order in $B/B_{\rm hfs}$ we obtain

$$\begin{aligned}\varepsilon_\pm(m_F) = -g_I\mu_N m_F B &- \tfrac{1}{4}a_{\rm hfs} \\ &\pm \tfrac{1}{2}|a_{\rm hfs}|(I+\tfrac{1}{2})[1+\tilde{m}_F B/B_{\rm hfs} + \tfrac{1}{2}(1-\tilde{m}_F^2)(B/B_{\rm hfs})^2 + \cdots].\end{aligned} \tag{5.102}$$

The linear and quadratic contributions are referred to as *linear* and *quadratic* Zeeman effects. The linear terms correspond to the *low-field tangents* indicated by the dotted lines in Fig. 5.5. Note that the quadratic shift is strongest for small $|m_F|$, in particular for $m_F = 0$. The quadratic shift is always positive for the upper (+) and negative for the lower (−) manifold as is evident from Fig. 5.5. Restricting ourselves to the leading terms we distinguish two cases:

a.) $0 < |m_F| < I + \frac{1}{2}$: In this case the linear terms are dominant,

$$\varepsilon_\pm(m_F) = -g_I \mu_N m_F B - \tfrac{1}{4} a_{\rm hfs} \pm \tfrac{1}{2} |a_{\rm hfs}| (I + \tfrac{1}{2})(1 + \tilde{m}_F B/B_{\rm hfs}) + \cdots . \tag{5.103}$$

This expression corresponds to the low-field tangents indicated by the dotted lines in Fig. 5.9. Expanding Eq. (5.97) to first order in $B/B_{\rm hfs}$we find

$$A_\pm^2 \simeq \tfrac{1}{2}(1 \pm \tilde{m}_F)\,[1 \pm (B/B_{\rm hfs})(1 \mp \tilde{m}_F) + \cdots] . \tag{5.104}$$

b.) $m_F = 0$: Clock states correspond to the case of *strong coupling (weak asymmetry)* as defined in Appendix H.3. The Breit-Rabi formula takes a quadratic field dependence

$$\varepsilon_\pm(0) = -\tfrac{1}{4} a_{\rm hfs} \pm \tfrac{1}{2} |a_{\rm hfs}| (I + \tfrac{1}{2}) \pm \tfrac{1}{4} |a_{\rm hfs}| (I + \tfrac{1}{2})(B/B_{\rm hfs})^2 + \cdots . \tag{5.105}$$

The absence of a linear field dependence in the limit $B \to 0$ makes these levels insensitive to small magnetic fields, which explains their importance for application in *atomic clocks.* Expanding Eq. (5.99) in powers of $B/B_{\rm hfs}$ we note that the linear term is absent and the amplitudes of the coefficients can be approximated by

$$A_\pm^2 \simeq \tfrac{1}{2}\left[1 \pm (B/B_{\rm hfs})^2 + \cdots\right] . \tag{5.106}$$

Crossover field ($B = |B_{\rm hfs}|$)**:** Equating the expressions (5.100) and (5.103) for the high- and low-field tangents we obtain an expression for the intersection point,

$$\mu_+ B(1 + \tilde{m}_F B_{\rm hfs}/B) = |a_{\rm hfs}|(I + \tfrac{1}{2})(1 + \tilde{m}_F B/B_{\rm hfs}). \tag{5.107}$$

Solving for B we find for the intersection point $B = |B_{\rm hfs}| = |a_{\rm hfs}|(I + \frac{1}{2})/\mu_+$. This point marks the crossover between the low-field and high-field regions.

5.4.3 High-field limit

For magnetic fields much higher than the hyperfine field but much lower than the fine-structure field ($|B_{\rm hfs}| \ll B \ll |B_{\rm fs}|$) the hyperfine coupling is weak compared to the Zeeman interaction whereas the fine-structure coupling is still strong. For increasing magnetic field, this manifests itself as a crossover from the hyperfine coupling between **J** and **I** ($B \ll |B_{\rm hfs}|$) to Zeeman coupling of **J** and **I** individually to the magnetic field ($B \gg |B_{\rm hfs}|$) - see Fig. 5.7. This crossover is known as the *Back-Goudsmit effect* and is similar to the *Paschen-Back effect* in the fine structure. Therefore, in the high-field limit the atomic Hamiltonian

$$\mathcal{H} = (\mathcal{H}_{\rm fs} + \mathcal{H}_Z) + \mathcal{H}_{IJ} \tag{5.108}$$

is best analyzed in the *uncoupled* hyperfine representation $\{|nlsjm_jIm_I\rangle\}$ in which $\mathcal{H}_Z$ is diagonal and $\mathcal{H}_{IJ}$ is the perturbation. In this basis and for given values of n, l, s, j the perturbation matrix is given by

$$\mathcal{H}^{IJ}_{m_j' m_I'; m_j m_I} = (a_{\rm hfs}/\hbar^2)\langle jm_j' Im_I'|\mathbf{I}\cdot\mathbf{J}|jm_jIm_I\rangle, \tag{5.109}$$

which can be written in the form

$$\mathcal{H}^{IJ}_{m_j' m_I'; m_j m_I} = (a_{\rm hfs}/\hbar^2)\langle jm_j' Im_I'|I_zJ_z + \tfrac{1}{2}\left(I_+J_- + I_-J_+\right)|jm_jIm_I\rangle. \tag{5.110}$$

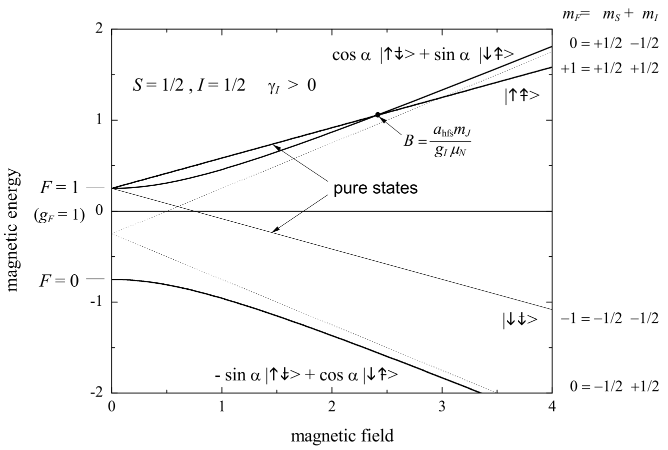

Figure 5.6: Crossing of the nuclear Zeeman levels at at $B \simeq 16.7$ T in hydrogen. This happens when the nuclear Zeeman shift equals the hyperfine spitting. Note that the figure is *not* to scale (the nuclear moment was chosen to be *artificially large* to show both the hyperfine splitting and the crossing in one plot).

As only the *diagonal matrix elements* of a weak perturbation *contribute to first order* in perturbation theory (see Appendix G.3.4 - weak coupling), in high fields the hyperfine shift is given by $\Delta E^{IJ}_{m_j m_I}\left(n\,{}^{2s+1}L_j\right) = a_{\text{hfs}} m_I m_j$ and the *asymptotic field dependence* (dashed lines in Fig. 5.5) can be expressed as

$$\Delta E_{m_j m_I}\left(n\,{}^{2s+1}L_j\right) = a_{\text{hfs}} m_I m_j + (g_J \mu_B m_j - g_I \mu_N m_I) B. \tag{5.111}$$

Note that this expression is valid for arbitrary values of j and I.

5.4.3.1 Very-high-field limit $(B > a_{\text{hfs}} m_j / g_I \mu_N)$

The levels in the hyperfine manifold with the largest multiplicity will cross when the nuclear Zeeman shift becomes larger than the zero-field hyperfine splitting (see Fig. 5.6). This happens for $g_I \mu_N B > a_{\text{hfs}} m_j > 0$ (presuming j to be a good quantum number). Beyond the crossing the ordering of the nuclear sublevels is the same in the lower and upper manifold, as is to be expected in sufficiently high field. Interestingly, at $B = a_{\text{hfs}} m_j / g_I \mu_N$ the overall hyperfine shift is independent of m_I, $\Delta E_{m_j m_I}\left(n\,{}^{2s+1}L_j\right) = g_J \mu_B m_j B$. This means that all m_I levels of a manifold with $m_j > 0$ coincide, which is an example of *accidental degeneracy*. For the ground states of atomic hydrogen, deuterium and tritium this happens in the manifolds with $m_s = \frac{1}{2}$ at $B \simeq 16.7$ T.

5.4.4 Low-field limit - linear Zeeman shift and hyperfine g factor (g_F)

For magnetic fields much lower than the hyperfine field $(B \ll |B_{\text{hfs}}|)$ the angular momenta $\mathbf{J}$ and $\mathbf{I}$ are strongly hyperfine coupled (by $\mathcal{H}_{IJ}$) to form the total electronic angular momentum $\mathbf{F} = \mathbf{J} + \mathbf{I}$ (see Fig. 5.7). Under these conditions the atomic Hamiltonian

$$\mathcal{H} = (\mathcal{H}_{\text{fs}} + \mathcal{H}_{IJ}) + \mathcal{H}_Z \tag{5.112}$$

is best analyzed in the *coupled* representation $\{|nlsjIFm_F\rangle\}$, where $\mathbf{L} \cdot \mathbf{S}$ and $\mathbf{J} \cdot \mathbf{I}$ are diagonal and $\mathcal{H}_Z$ is the perturbation. In this basis and for given values of n, l, s, j, I, F the perturbation matrix is given by

$$\mathcal{H}^Z_{F'm_{F'};Fm_F} = \langle F'm_{F'}| g_J \mu_B J_z - g_I \mu_N I_z \,|Fm_F\rangle\, B/\hbar. \tag{5.113}$$

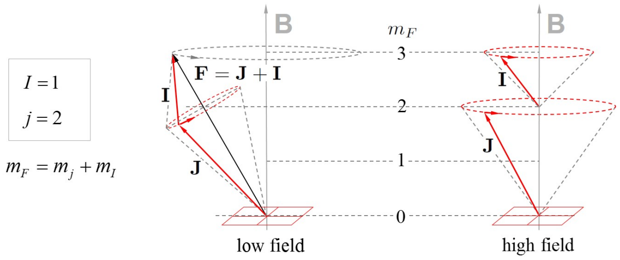

Figure 5.7: Precession of angular momenta in an externally applied magnetic field for the example $j = 2$, $I = 1$. In *low* fields $\mathbf{J}$ and $\mathbf{I}$ are hyperfine coupled to form the total atomic angular momentum $\mathbf{F} = \mathbf{J} + \mathbf{I}$, which precesses slowly about the field direction as a result of a weak Zeeman coupling, $\mathcal{H}_Z$, to the magnetic field; this is most conveniently described in the *coupled* basis $\{|F, m_F\rangle\}$. In *high* fields $\mathbf{J}$ and $\mathbf{I}$ are predominantly Zeeman coupled to the external field and precess mostly independently about the field direction; this is best described in the *uncoupled* basis $\{|j, m_j, I, m_I\rangle\}$. Note that $m_F = m_j + m_I$ is a good quantum number in both limits.

Expressing the nuclear magneton into the Bohr magneton, $\mu_N \equiv (m_e/m_p)\mu_B$, and limiting ourselves to the diagonal terms, we obtain the following expression for the energy shift (Zeeman shift)

$$\Delta E^Z_{F,m_F}\left(n\,^{2s+1}L_j\right) = \langle jIFm_F| g_J J_z - g_I I_z (m_e/m_p)\,|jIFm_F\rangle\,\mu_B B/\hbar, \tag{5.114}$$

This expression is valid to only first order in perturbation theory because $\mathcal{H}_Z$ is in *not* diagonal in the coupled representation: only the *diagonal matrix elements* of a weak perturbation *contribute to first order* (see Appendix G.3.4 - weak coupling). As the operators J_z and I_z cannot change m_j and m_I, the quantum number m_F has to be conserved. This is a consequence of the m_F *selection rule* (3.89), $m_F = m_j + m_I$. However, J_z and I_z do *not* conserve F (compare Problem 4.12). Only in *low* fields the perturbation can be made sufficiently weak to neglect the off-diagonal terms and treat both F and m_F as good quantum numbers of the atomic Hamiltonian (4.194).

The physics in low field is completely analogous to the low-field limit of the fine-structure: in sufficiently low fields the magnetic moment of the atom will scale proportionally to the total atomic angular momentum $\mathbf{F}$,

$$\boldsymbol{\mu}_F \equiv \gamma_F \mathbf{F} \equiv -g_F \mu_B\,(\mathbf{F}/\hbar) \qquad \text{for } B \to 0 \text{ and } F > 0. \tag{5.115}$$

Note that γ_F and g_F are defined with opposite sign, just as we did for γ_L, γ_e and γ_J; as will be shown the sign of g_F can be positive or negative depending on F. We only have to address the case $F > 0$ because for $F = 0$ the magnetic moment must be absent. Hence, the Zeeman energy can be described by the effective Hamiltonian $\mathcal{H}_Z = -\boldsymbol{\mu}_F \cdot \mathbf{B}$. This Hamiltonian yields a Zeeman shift on top of the fine- and hyperfine structure shifts determined by the quantum numbers n, l, s, j, I, F :

$$\Delta E^Z_{F,m_F} = g_F \mu_B B \langle Fm_F|(F_z/\hbar)\,|Fm_F\rangle = g_F \mu_B m_F B \qquad \text{for } B \to 0\ . \tag{5.116}$$

This expression corresponds to the *low-field tangents* indicated by the dotted lines in Fig. 5.5. Note that the effective Hamiltonian is diagonal in the $\{|nlsjIFm_F\rangle\}$ basis.

In search for g_F we compare Eqs. (5.114) and (5.116) and obtain for $F > 0$

$$g_F = g_J \langle jIF||J||jIF\rangle - g_I (m_e/m_p) \langle jIF||I||jIF\rangle. \tag{5.117}$$

To arrive at this result we applied the Wigner-Eckart theorem. As J_z, I_z and F_z are diagonal in the $\{|nlsjIFm_F\rangle\}$ basis, the matrix elements of J_z and I_z become for $F > 0$

$$\langle nlsjIFm_F|\,J_z\,|nlsjIFm_F\rangle = \langle jIF\,\|J\|\,jIF\rangle\,\langle Fm_F|\,F_z\,|Fm_F\rangle \tag{5.118a}$$

$$\langle nlsjIFm_F|\,I_z|nlsjIFm_F\rangle = \langle jIF\,\|I\|\,jIF\rangle\,\langle Fm_F|\,F_z\,|Fm_F\rangle\,, \tag{5.118b}$$

where the proportionality constants $\langle jIF\,\|J\|\,jIF\rangle$ and $\langle jIF\,\|I\|\,jIF\rangle$ are *reduced matrix elements* and *independent of* m_F. Note that since $F_z = J_z + I_z$ we find by adding Eqs. (5.118a) and (5.118b) that the reduced matrix elements add up to unity,

$$\langle jIF||J||jIF\rangle + \langle jIF||I||jIF\rangle = 1 = \langle lsj\,\|F\|\,lsj\rangle \quad \text{(for } F > 0\text{)}. \tag{5.119}$$

With the aid of this expression we obtain for $F > 0$

$$g_F = \begin{cases} -g_I(m_e/m_p) + [g_J + g_I(m_e/m_p)]\langle jIF||J||jIF\rangle \simeq g_J\langle jIF||J||jIF\rangle & \text{for } j \neq 0 \\ -g_I(m_e/m_p) & \text{for } j = 0. \end{cases} \tag{5.120}$$

Note that the derivation is valid for arbitrary values of $\mathbf{J}$ and $\mathbf{I}$. For hydrogen-like atoms the condition $j \neq 0$ is always satisfied. The projections of $\mathbf{I}$ and $\mathbf{J}$ along the total angular momentum vector $\mathbf{F}$, *i.e.* $\mathbf{I}\cdot\mathbf{F}$ and $\mathbf{J}\cdot\mathbf{F}$, are conserved while $\mathbf{F}$ precesses about $\mathbf{B}$,

$$\langle nlsjIFm_F|\,J_z\,|nlsjIFm_F\rangle = \frac{\langle jIFm_F|\,(\mathbf{J}\cdot\mathbf{F})\,F_z\,|jIFm_F\rangle}{\langle jIFm_F|\,\mathbf{F}^2\,|jIFm_F\rangle}. \tag{5.121}$$

Since $\mathbf{J}\cdot\mathbf{F}$ is diagonal in the low-field basis,

$$\mathbf{J}\cdot\mathbf{F} = \mathbf{J}^2 + \mathbf{J}\cdot\mathbf{I} = \mathbf{J}^2 + \tfrac{1}{2}[\mathbf{F}^2 - \mathbf{J}^2 - \mathbf{I}^2] = \tfrac{1}{2}[\mathbf{F}^2 + \mathbf{J}^2 - \mathbf{I}^2],$$

we find by comparison with Eq. (5.118a)

$$\langle jIF||J||jIF\rangle = \frac{\langle jIFm_F|\,\mathbf{J}\cdot\mathbf{F}\,|jIFm_F\rangle}{\langle jIFm_F|\,\mathbf{F}^2\,|jIFm_F\rangle} = \frac{F(F+1) + j(j+1) - I(I+1)}{2F(F+1)} \quad \text{for } F > 0. \tag{5.122}$$

which is independent of m_F, as it should for a reduced matrix element. The same result can be obtained with the algebraic procedure demonstrated in Problem 4.14.

For the important special case $j = \frac{1}{2}$ the expression (5.120) reduces to the form

$$g_F \simeq \pm g_J \frac{1}{2I+1} \qquad (F = I \pm \tfrac{1}{2};\ j = \tfrac{1}{2};\ F > 0). \tag{5.123}$$

For $F = 0$ also $m_F = 0$ and g_F has no meaning. Note that g_F is always *negative* for the state with the *smallest* multiplicity $\left(F = I - \frac{1}{2} > 0\right)$, *i.e.* for electronic and nuclear spins coupled in opposite directions. This is intuitively clear because for $I \geq 1$ the nuclear spin dominates the angular momentum of the $j = \frac{1}{2}$ atom whereas the electron determines the magnetic moment. Hence the atoms behave like a classically spinning ball of positive charge. For similar reasons, g_F is always *positive* for the state with the *highest* multiplicity $\left(F = I + \frac{1}{2}\right)$. The sign of the nuclear gyromagnetic ratio is irrelevant in this context because the contribution of the nuclear magnetic moment is negligibly small anyhow.

5.4.5 Low-field limit - quadratic Zeeman shift

In the expansion (5.102) we obtained the expression for the *quadratic Zeeman shift* for the special case $j = \frac{1}{2}$.[1] For arbitrary value of j the quadratic shift can be calculated with the aid of second-order perturbation theory,

$$\Delta E^{(2)Z}_{F,m_F}\left(n\,^{2s+1}L_j\right) = \sum_{F'} \frac{|\langle IjF'm_F|g_J\mu_B J_z - g_I\mu_N I_z|IjFm_F\rangle B/\hbar|^2}{E_{F,m_F} - E_{F',m_F}}. \tag{5.124}$$

---

[1] This quadratic shift is not to be confused with the diamagnetic contribution, which is much weaker but quadratic in B at the level of the Hamiltonian.

Note that this contribution indeed scales like B^2. As J_z and I_z conserve m_F the Zeeman operator couples states of different $F' \in \{|I-j|, \cdots, I+j\}$ for given value of m_F.

We demonstrate the procedure for the special case $j = \frac{1}{2}$, in which only two hyperfine levels are coupled and the result is already known from Eq. (5.102). The energy splitting may be approximated by its zero-field value; i.e., by the interval rule (5.62), $\Delta W_F = a_{\mathrm{hfs}} F = a_{\mathrm{hfs}}(I + \frac{1}{2})$; note that the energy splitting also has a field dependence but as this leads to a cubic shift it is not included here. The quadratic shifts of the upper ($F = I + \frac{1}{2}$) and lower ($F = I - \frac{1}{2}$) hyperfine levels (of given m_F) only differ in the sign, with the quadratic shifts of the upper manifold all positive and those of the lower manifold all negative. For the upper/lower manifold the quadratic shift becomes

$$\Delta E^{(2)Z}_{F,m_F}\left(n\,{}^{2s+1}L_j\right) = \pm \frac{|\langle IjF'm_F|g_J\mu_B J_z - g_I\mu_N I_z|IjFm_F\rangle B/\hbar|^2}{a_{\mathrm{hfs}}(I+\frac{1}{2})}. \tag{5.125}$$

where $F' = I + \frac{1}{2}$ refers to the upper and $F = I - \frac{1}{2}$ to the lower manifold. Adding and subtracting $g_I\mu_N J_z$ and using the orthogonality relation $\langle IjF'm_F|IjFm_F\rangle = 0$ as well as the definitions (5.90a) and (5.90b) the Eq. (5.125) can be reduced to

$$\Delta E^{(2)Z}_{F,m_F}\left(n\,{}^{2s+1}L_j\right) = \pm a_{\mathrm{hfs}}(I+\tfrac{1}{2})\,(B/B_{\mathrm{hfs}})^2\,|\langle IjF'm_F|J_z/\hbar|IjFm_F\rangle|^2. \tag{5.126}$$

The matrix element follows by Clebsch-Gordan decomposition

$$\langle IjF'm_F|J_z/\hbar|IjFm_F\rangle = \sum_{m_j,m_I} m_j \langle F'm_F|Im_Ijm_j\rangle\langle Im_Ijm_j|Fm_F\rangle. \tag{5.127}$$

Noting that $m_I = m_F - m_j$ and turning to $3j$ symbols (using the property that $2I+1+F+F'$ and $2I - 2m_F$ are always even) we find

$$\langle IjF'm_F|J_z/\hbar|IjFm_F\rangle = \sum_{m_j=\pm 1/2} m_j\sqrt{2(I+1)2I}\begin{pmatrix} I & I+\frac{1}{2} & \frac{1}{2} \\ (m_F-m_j) & -m_F & m_j \end{pmatrix}\begin{pmatrix} I & I-\frac{1}{2} & \frac{1}{2} \\ (m_F-m_j) & -m_F & m_j \end{pmatrix}. \tag{5.128}$$

Using Eqs. (J.17) this becomes

$$\langle IjF'm_F|J_z/\hbar|IjFm_F\rangle = \sum_{m_j=\pm 1/2} (-1)^{m_j-\frac{3}{2}}\frac{1}{2}\sqrt{\frac{I+1\pm(m_F-m_j)}{(2I+1)}}\sqrt{\frac{I\mp(m_F-m_j)}{(2I+1)}}. \tag{5.129}$$

Both the $m_j = -\frac{1}{2}$ and the $m_j = \frac{1}{2}$ contribution yield the same result and adding these we obtain

$$\langle IjF'm_F|J_z/\hbar|IjFm_F\rangle = \tfrac{1}{2}\sqrt{1-\tilde{m}_F^2}. \tag{5.130}$$

Substituting this expression into Eq. (5.126) we arrive at

$$\Delta E^{(2)Z}_{F,m_F}\left(n\,{}^{2s+1}L_j\right) = \pm\tfrac{1}{4}a_{\mathrm{hfs}}(I+\tfrac{1}{2})\,(B/B_{\mathrm{hfs}})^2\,(1-\tilde{m}_F^2). \tag{5.131}$$

Note that we indeed regained the quadratic term of Eq. (5.102). Since $\tilde{m}_F^2 \leq 1$ we re-established that the quadratic Zeeman shift is *largest* for the state of *smallest* $|m_F|$. This is important in particular for phenomena which are insensitive for the linear Zeeman effect (see e.g. [60]).

5.5 Ground state hyperfine structure of hydrogen-like atoms

5.5.1 Hydrogen (^{1}H) in the electronic ground state $^2S_{1/2}$ ($I = 1/2$)

The electronic ground state of atomic hydrogen is the $1\,{}^2S_{1/2}$ state. In Fig. 5.8 the low-field limit can be recognized for the case of the ground state of atomic hydrogen ($j = s = I = \frac{1}{2}$; $l = 0$).

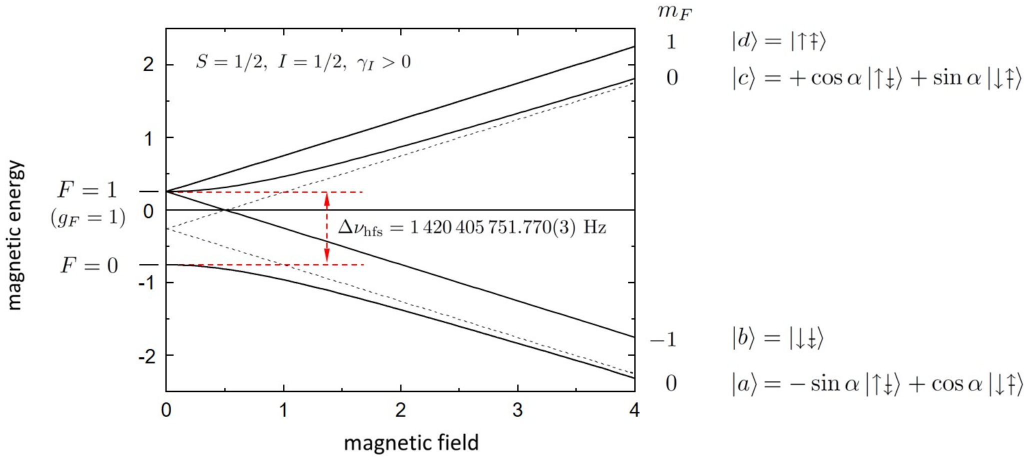

Figure 5.8: Breit-Rabi diagram for the hyperfine structure of atomic hydrogen in its ground state $1^2S_{1/2}$. Indicated is the clock transition ($\lambda=21\,\text{cm}$) on which the hydrogen maser is based and famous for its astrophysical importance. The dotted lines correspond to the high-field asymptotes - see Eq. (5.111). The magnetic field is given in units of the hyperfine splitting $a_{\rm hfs}/\mu_+=507$ Gauss. Note that the upper (lower) branches correspond in high fields with electron spin up (down). The zero-field hyperfine splitting is calculated to an accuracy of $1:10^4$ in Section 5.3.6. The limiting behavior is: a) $B\to\infty:\sin\alpha\to0$; b) $B\to0:\cos^2\alpha\to{}^1\!/_2$. The upper two levels cross at $B\approx16.7$ T.

Because $l=0$ there is no orbital magnetic moment and $g_J=g_e\simeq2$. For $F=I+s=1$ we observe the splitting into a triplet and using Eq. (5.120) we calculate for the effective g factor $g_F\simeq1$. For the stretched spin state $m_F=1$ the Zeeman shift is given by $\Delta E^{\rm Z}_{F,m_F}\simeq\mu_BB$, which is exactly what we expect because neglecting the nuclear spin we are left with the contribution of the electron spin, $\Delta E^{\rm Z}_{s,m_s}=g_e\mu_Bm_sB\simeq\mu_BB$.

Accurate expressions for the field dependence of the hyperfine levels are obtained with Eqs. (5.92) and (5.105). For nuclear spin $I=\frac12$, electronic spin $s=\frac12$ and $\gamma_I>0$ we obtain (see Fig. 5.8)

$$\varepsilon_\pm(m_F)=\begin{cases}+\frac14a_{\rm hfs}\pm\frac12\mu_-B & m_F=\pm1\\ -\frac14a_{\rm hfs}\pm\frac12a_{\rm hfs}\sqrt{1+(B/B_{\rm hfs})^2} & m_F=0\,,\end{cases}\tag{5.132}$$

The hyperfine field is $B_{\rm hfs}=a_{\rm hfs}/\mu_+\simeq507$ Gauss. For $m_F=0$ the coupled eigenstates are[1]

$$|F_{\rm max},0\rangle=+\cos\alpha|\uparrow⤈\rangle+\sin\alpha\,|\downarrow⤉\rangle,\tag{5.133a}$$

$$|F_{\rm min}\,,0\rangle=-\sin\alpha\,|\uparrow⤈\rangle+\cos\alpha|\downarrow⤉\rangle.\tag{5.133b}$$

The phase factors determining the sign of the coefficients are chosen in accordance with the phase convention for the $(I=\frac12\times S=\frac12)$ Clebsch-Gordan decomposition of Appendix J.2.1. The field dependence of the coefficients is given by Eq. (5.99), which reduces for small magnetic fields to

$$A_\pm^2\simeq\tfrac12\left[1\pm(B/B_{\rm hfs})^2+\cdots\right]\qquad(B\ll|B_{\rm hfs}|).\tag{5.134}$$

Using this procedure we find for the coupled states $|a\rangle$, $|b\rangle$, $|c\rangle$ and $|d\rangle$ (in order of increasing energy)

$$\begin{aligned}|d\rangle&=|\uparrow⤉\rangle\\|c\rangle&=+\cos\alpha|\uparrow⤈\rangle+\sin\alpha|\downarrow⤉\rangle\\|b\rangle&=|\downarrow⤈\rangle\\|a\rangle&=-\sin\alpha|\uparrow⤈\rangle+\cos\alpha|\downarrow⤉\rangle.\end{aligned}\tag{5.135}$$

---

[1] In this notation $|\uparrow\rangle=|s,+\frac12\rangle$ and $|\downarrow\rangle=|s,-\frac12\rangle$ refer to the electron spin and $|⤉\rangle=|I,+\frac12\rangle$ and $|⤈\rangle=|I,-\frac12\rangle$, to the proton spin.

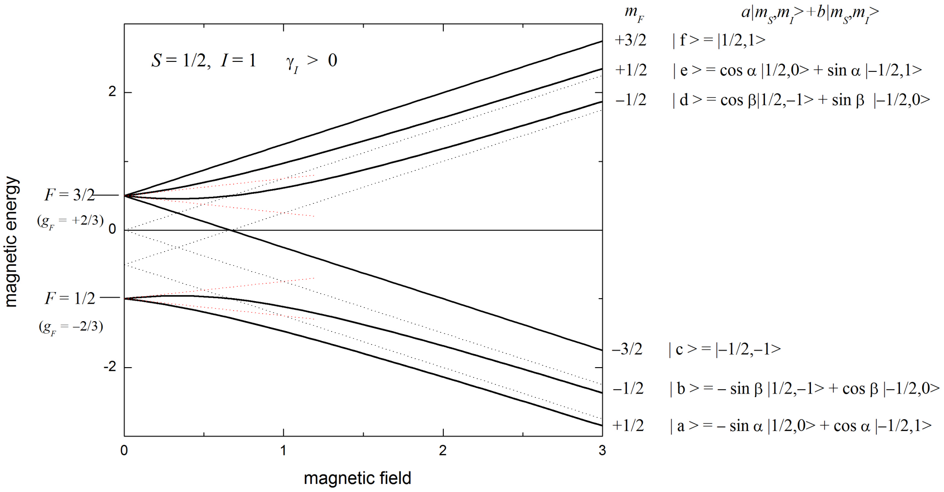

Figure 5.9: Hyperfine structure of the ${}^2S_{1/2}$ electronic ground states of deuterium (D) and ^{6}Li. The magnetic field is given in units of the hyperfine splitting, 175 Gauss for D and 81.4 Gauss for ^{6}Li. The dotted lines correspond to the high-field asymptotes - see Eq. (5.111). Note that the lower manifold ($F = \frac{1}{2}$) is inverted because its g-factor is negative ($g_F = -2/3$). The limiting behavior is: a) $B \to \infty : \sin\alpha, \sin\beta \to 0$; b) $B \to 0 : \cos^2\alpha, \cos^2\beta \to 2/3,\ 1/3$.

For $B \to 0 : \alpha = \pi/4$, *i.e.* $\sin^2\alpha = \cos^2\alpha = 1/2$ and $|a\rangle = |0,0\rangle$, $|b\rangle = |1,-1\rangle$, $|c\rangle = |1,0\rangle$ and $|d\rangle = |1,+1\rangle$. For $B \to \infty : \alpha \to 0$, *i.e.* $\sin\alpha \simeq \alpha \simeq 0$ and $\cos\alpha \simeq 1$.

5.5.2 Deuterium (^{2}H) and ^{6}Li in the electronic ground state ${}^2S_{1/2}$ $(I = 1)$

The heavy hydrogen isotope deuterium (^{2}H) has one electron. Like hydrogen the ground state configuration is $1s$ and the spin-orbit type is $1\,{}^2S_{1/2}$. The ^{6}Li atom in its electronic ground state has configuration $1s^2 2s$ and is of the spin-orbit type $2\,{}^2S_{1/2}$. With orbital angular momentum $L = 0$, electronic spin $s = \frac{1}{2}$ and nuclear spin $I = 1$ the quantum number for the total angular momentum can have the values $F = I \pm \frac{1}{2} = \frac{3}{2},\ \frac{1}{2}$. Both elements have a positive gyromagnetic ratio. Hence, the Fermi contact interaction is positive ($a_{\text{hfs}} > 0$) and the hyperfine structure regular; i.e., the manifold with the highest multiplicity $\left(F = \frac{3}{2}\right)$ has the highest energy. Since $\gamma_I > 0$ the energies of the states are given by

$$\varepsilon_\pm(m_F) = \begin{cases} -g_I\mu_N m_F B - \frac{1}{4}a_{\text{hfs}} + \frac{3}{4}a_{\text{hfs}}(1 \pm B/B_{\text{hfs}}) & m_F = \pm\frac{3}{2} \\ -g_I\mu_N m_F B - \frac{1}{4}a_{\text{hfs}} \pm \frac{3}{4}a_{\text{hfs}}\sqrt{1 + \frac{4}{3}m_F B/B_{\text{hfs}} + (B/B_{\text{hfs}})^2} & m_F = \pm\frac{1}{2}\,. \end{cases} \tag{5.136}$$

The hyperfine crossover field $B_{\text{hfs}} = (I + \frac{1}{2})a_{\text{hfs}}/\mu_+ \simeq 175$ Gauss in the case of deuterium and 81.4 Gauss in the case of ^{6}Li (see Table 5.1). The Breit-Rabi diagram for this case is shown in Fig. 5.9. The upper manifold is regular $\left(g_F = \frac{2}{3}\right)$. The lower manifold ($F = \frac{1}{2}$) is inverted because its g factor is negative $\left(g_F = -\frac{2}{3}\right)$. The phase factors determining the sign of the coefficients are in accordance with the $(1 \times 1/2)$ Clebsch-Gordan decomposition of Appendix J.2.1. Because $m_F = m_I + m_s$ is a good quantum number the eigenstates can be expressed for any field in the form

$$|F_{\max}, m_F\rangle = +\cos\alpha|\uparrow; 1, \left(m_F - \tfrac{1}{2}\right)\rangle + \sin\alpha|\downarrow; 1, \left(m_F + \tfrac{1}{2}\right)\rangle \tag{5.137a}$$

$$|F_{\min}, m_F\rangle = -\sin\alpha|\uparrow; 1, \left(m_F - \tfrac{1}{2}\right)\rangle + \cos\alpha|\downarrow; 1, \left(m_F + \tfrac{1}{2}\right)\rangle. \tag{5.137b}$$

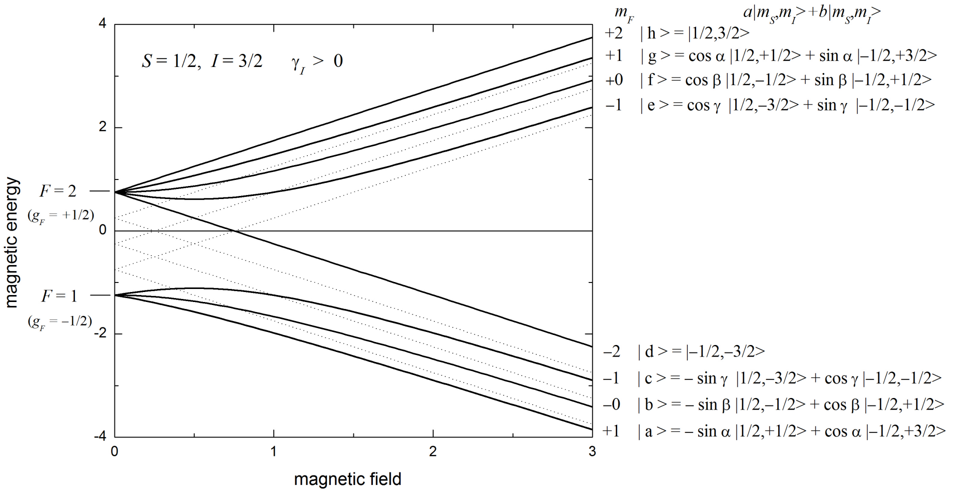

Figure 5.10: Hyperfine structure of ${}^2S_{1/2}$ electronic ground states with $I = \frac{3}{2}$. The magnetic field is given in units of the hyperfine splitting, 287 G for ^{7}Li, 633 G for ^{23}Na, 165 G for ^{39}K, 90 G for ^{41}K and 2.44 kG for ^{87}Rb. The dotted lines correspond to the high-field asymptotes - see Eq. (5.111). Note that the lower manifold ($F = 1$) is inverted because its g-factor is negative, $g_F = -\frac{1}{2}$. The limiting behavior is: a) $B \to \infty : \sin\alpha, \sin\beta, \sin\gamma \to 0$; b) $B \to 0 : \cos^2\alpha, \cos^2\beta, \cos^2\gamma \to 3/4, 2/4, 1/4$.

Here we use the notation of Eq. (5.93a). The field dependence of the coefficients is given by Eq. (5.97), which reduces for small magnetic fields to

$$A_\pm^2 \simeq \frac{1}{2}\left(1 \pm \tfrac{2}{3}m_F\right)\left[1 \pm B/B_{\rm hfs}\left(1 \mp \tfrac{2}{3}m_F\right) + \cdots\right] \quad (B \ll |B_{\rm hfs}|)\,. \tag{5.138}$$

5.5.3 The alkali atoms ^{7}Li, ^{23}Na, ^{39}K, ^{41}K and ^{87}Rb in the electronic ground state ${}^2S_{1/2}$ ($I = 3/2$)

The electronic ground state configuration of these alkali atoms is [He]2s for ^{7}Li, [Ne]3s for ^{23}Na, [Ar]4s for ^{39}K and ^{41}K, and [Kr]5s for ^{87}Rb. In all cases the term type is ${}^2S_{1/2}$. With orbital angular momentum $L = 0$, electronic spin $s = \frac{1}{2}$ and nuclear spin $I = \frac{3}{2}$ the quantum number for the total angular momentum can have the values $F = I \pm \frac{1}{2} = 2, 1$. All elements mentioned have a positive gyromagnetic ratio. Hence, the Fermi contact interaction is positive ($a_{\rm hfs} > 0$) and the hyperfine structure regular; i.e., the manifold with the highest multiplicity ($F = 2$) has the highest energy. For nuclear spin $I = \frac{3}{2}$, electronic spin $s = \frac{1}{2}$ and $\gamma_I > 0$ the energies of the coupled states are given by

$$\varepsilon_\pm(m_F) = \begin{cases} -g_I\mu_N m_F B - \frac{1}{4}a_{\rm hfs} + a_{\rm hfs}(1 \pm B/B_{\rm hfs}), & m_F = \pm 2 \\ -g_I\mu_N m_F B - \frac{1}{4}a_{\rm hfs} \pm a_{\rm hfs}\sqrt{1 + m_F B/B_{\rm hfs} + (B/B_{\rm hfs})^2}, & m_F = \pm 1 \\ -g_I\mu_N m_F B - \frac{1}{4}a_{\rm hfs} \pm a_{\rm hfs}\sqrt{1 + (B/B_{\rm hfs})^2}, & m_F = 0\,. \end{cases} \tag{5.139}$$

The hyperfine crossover field $B_{\rm hfs} = (I + \frac{1}{2})a_{\rm hfs}/\mu_+ \simeq 287$ G in the case of ^{7}Li, 633 G in the case of ^{23}Na, 165 G in the case of ^{39}K, 90 G in the case of ^{41}K and 2.44 kG in the case of ^{87}Rb (see Table 5.1). The Breit-Rabi diagram for this case is shown in Fig. 5.10. The upper manifold ($F = 2$) is regular $\left(g_F = \frac{1}{2}\right)$. The lower manifold ($F = 1$) is inverted because its g factor is negative $\left(g_F = -\frac{1}{2}\right)$. The phase factors determining the sign of the coefficients are in accordance with the

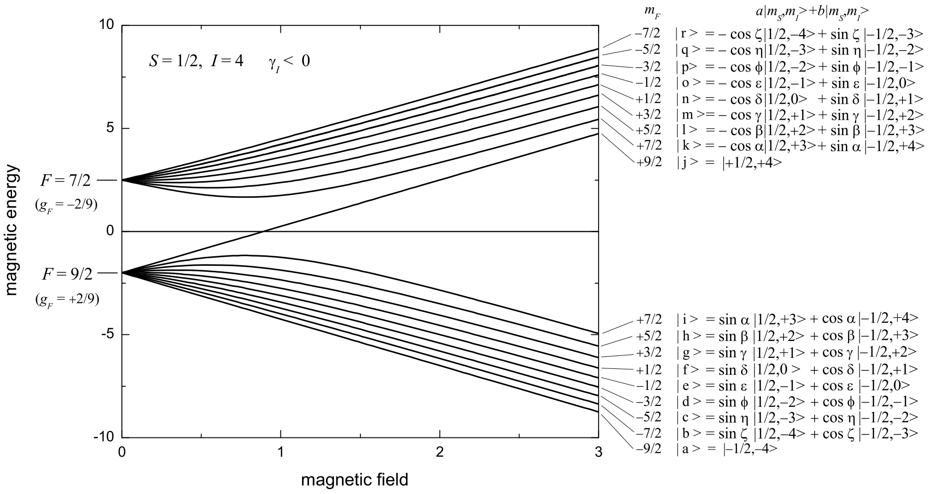

Figure 5.11: Example of an inverted hyperfine structure: the electronic ground state ${}^2S_{1/2}$ of ^{40}K ($I = 4, \gamma_N < 0$). The magnetic field is given in units of the hyperfine splitting, 459 G for ^{40}K. Note that the manifold with the smallest multiplicity ($F = \frac{7}{2}$) is also inverted because its g-factor is negative, $g_F = -2/9$. The limiting behavior is: a) $B \to \infty : \sin\alpha, \cdots, \sin\zeta \to 0$; b) $B \to 0 : \cos\alpha, \cdots, \cos\zeta \to 8/9, \cdots, 1/9$.

(3/2 × 1/2) Clebsch-Gordan decomposition of Appendix J.2.1. Because $m_F = m_I + m_s$ is a good quantum number the eigenstates can be expressed for any field in the form

$$|F_{\max}, m_F\rangle = +\cos\alpha_+ |\uparrow; \tfrac{3}{2}, \left(m_F - \tfrac{1}{2}\right)\rangle + \sin\alpha_+ |\downarrow; \tfrac{3}{2}, \left(m_F + \tfrac{1}{2}\right)\rangle \tag{5.140a}$$

$$|F_{\min}, m_F\rangle = -\sin\alpha_+ |\uparrow; \tfrac{3}{2}, \left(m_F - \tfrac{1}{2}\right)\rangle + \cos\alpha_+ |\downarrow; \tfrac{3}{2}, \left(m_F + \tfrac{1}{2}\right)\rangle. \tag{5.140b}$$

Here we use the notation of Eq. (5.93a). For $0 < |m_F| < 2$ the field dependence of the coefficients is given by Eq. (5.97), which reduces for small magnetic fields to

$$A_\pm^2 \simeq \tfrac{1}{2}\left(1 \pm \tfrac{1}{2} m_F\right)\left[1 \pm B/B_{\mathrm{hfs}}\left(1 \mp \tfrac{1}{2} m_F\right) + \cdots\right] \qquad (B \ll |B_{\mathrm{hfs}}|). \tag{5.141}$$

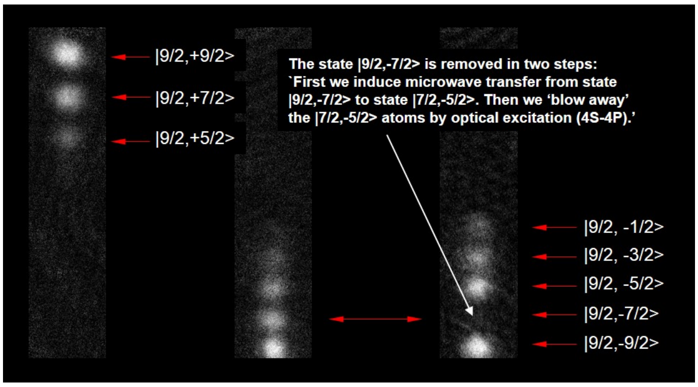
For $m_F = 0$ the coefficients are given by Eq. (5.99) and become in low field

$$A_\pm^2 \simeq \tfrac{1}{2}\left[1 \pm (B/B_{\mathrm{hfs}})^2 + \cdots\right] \qquad (B \ll |B_{\mathrm{hfs}}|). \tag{5.142}$$

5.5.4 Potassium-40 in the electronic ground state ${}^2S_{1/2}\,(I = 4)$ - negative hyperfine shift

The final example to be discussed in this section on the hyperfine interaction in hydrogen-like systems is the electronic ground state of ^{40}K. This case is special because the ^{40}K nucleus has a *negative* gyromagnetic ratio, which implies that also the Fermi contact interaction is negative ($a_{\mathrm{hfs}} < 0$). Like the other atomic isotopes of potassium the electronic ground-state configuration is [Ar]4s with term type ${}^2S_{1/2}$. With orbital angular momentum $L = 0$, electronic spin $s = \frac{1}{2}$ and nuclear spin $I = 4$ the quantum number for the total angular momentum can have the values $F = I \pm \frac{1}{2} = \frac{9}{2}, \frac{7}{2}$. The manifold with the lowest multiplicity $\left(F = \frac{7}{2}\right)$ has the highest energy because the hyperfine shift is *negative* ($a_{\mathrm{hfs}} < 0$). This is called an inverted hyperfine structure. For nuclear spin $I = 4$, electronic spin $s = \frac{1}{2}$ and $\gamma_I < 0$ the energies are given by

$$\varepsilon_\pm(m_F) = \begin{cases} -g_I \mu_N m_F B - \frac{1}{4} a_{\mathrm{hfs}} + \frac{9}{4} a_{\mathrm{hfs}} (1 \pm B/\left|B_{\mathrm{hfs}}\right|), & m_F = \pm\frac{9}{2} \\ -g_I \mu_N m_F B - \frac{1}{4} a_{\mathrm{hfs}} \pm \frac{9}{4} \left|a_{\mathrm{hfs}}\right| \sqrt{1 + \frac{4}{9} m_F B/B_{\mathrm{hfs}} + (B/B_{\mathrm{hfs}})^2} & |m_F| = \frac{1}{2}, \cdots \frac{7}{2}. \end{cases} \tag{5.143}$$



The state |9/2,-7/2> is removed in two steps: `First we induce microwave transfer from state |9/2,-7/2> to state |7/2,-5/2>. Then we 'blow away' the |7/2,-5/2> atoms by optical excitation (4S-4P).'

Figure 5.12: Stern-Gerlach imaging of the hyperfine states of ^{40}K. From left to right the atoms are first transferred (using radio waves) from the upper half to the lower half of the lower hyperfine manifold ($F = \frac{9}{2}$ - see Fig. 5.11). Subsequently, the atoms are removed from the $|\frac{9}{2}, -\frac{7}{2}\rangle$ state in two steps: first they are transferred from the state $|\frac{9}{2}, -\frac{7}{2}\rangle$ to the state $|\frac{7}{2}, -\frac{5}{2}\rangle$ of the upper hyperfine manifold from which they are "blown away" with resonant light on the $4S \rightarrow 4P$ transition.

The hyperfine crossover field $B_{\rm hfs} = (I + \frac{1}{2})a_{\rm hfs}/\mu_+ \simeq -459$ G (see Table 5.1). The Breit-Rabi diagram for this case is shown in Fig. 5.11. An example of a corresponding Stern-Gerlach image is shown in Fig. 5.12.

The upper manifold ($F = \frac{7}{2}$) is inverted because its g factor is negative $\left(g_F = -\frac{2}{9}\right)$. The lower manifold ($F = \frac{9}{2}$) is regular $\left(g_F = \frac{2}{9}\right)$. The phase factors determining the sign of the coefficients are in accordance with the $(4 \times 1/2)$ Clebsch-Gordan decomposition of Appendix J.2.1. Because $m_F = m_I + m_s$ is a good quantum number the eigenstates can be expressed for any field in the form

$$|F_{\rm min}\,, m_F\rangle = -\cos\alpha|\uparrow; 4, \left(m_F - \tfrac{1}{2}\right)\rangle + \sin\alpha\,|\downarrow; 4, \left(m_F + \tfrac{1}{2}\right)\rangle \tag{5.144a}$$

$$|F_{\rm max}, m_F\rangle = +\sin\alpha\,|\uparrow; 4, \left(m_F - \tfrac{1}{2}\right)\rangle + \cos\alpha|\downarrow; 4, \left(m_F + \tfrac{1}{2}\right)\rangle. \tag{5.144b}$$

Here we use the notation of Eq. (5.93b). The field dependence of the coefficients is given by Eq. (5.97), which reduces for small magnetic fields to

$$A_\pm^2 \simeq \tfrac{1}{2}\left(1 \pm \tfrac{2}{9}m_F\right)\left[1 \pm B/B_{\rm hfs}\left(1 \mp \tfrac{2}{9}m_F\right) + \cdots\right] \qquad (B \ll |B_{\rm hfs}|)\,. \tag{5.145}$$

6

Electric hyperfine structure

Up to this point we treated the atomic nucleus as a simple electric point charge. This picture has its limitations because the nucleus has internal structure and a finite size. The electrostatic interaction of the electrons with the nucleus not only depends on the nuclear *charge* but also on its size and *structure*. The resulting deviations from the ideal Coulomb field give rise to the *electric* hyperfine structure of the atom.

In the semi-classical picture the nuclear structure manifests itself in the finite nuclear size and deviations from the spherical shape. From the quantum mechanical point of view the nuclear structure arises from the distribution and internal structure of the nucleons. As we shall find, in hydrogen ($I=\frac{1}{2}$) the electric hyperfine structure is absent because the nucleus is spherical. As we shall find the nuclei are nonspherical for $I>\frac{1}{2}$. This is the case for many alkali atoms but is of no consequence for the electronic *ground* states because the electronic charge distribution is spherical (^2S terms) and the coupling to electric multipole moments averages to zero.

6.1 Electrostatic interaction of an electron with a classical nucleus

In this section we restrict ourselves to the semi-classical picture in which the nuclear structure manifests itself only in the nuclear *size* and *shape*. To discuss the role of the nuclear structure we introduce the *unit-normalized* nuclear charge-density distribution $n(\mathbf{r}')$, with $\int n(\mathbf{r}')d\mathbf{r}'=1$, where $\mathbf{r}'$ is the position inside the nucleus defined with respect to the nuclear center of mass. In terms of $n(\mathbf{r}')$ the *electrostatic potential* at position $\mathbf{r}$ (also relative to the nuclear center) is given by (cf. Appendix E.3)

$$\varphi(\mathbf{r})=\frac{Ze}{4\pi\varepsilon_0}\int\frac{n(\mathbf{r}')}{|\mathbf{r}-\mathbf{r}'|}d\mathbf{r}'. \tag{6.1}$$

The corresponding *potential energy* of an electron at position $\mathbf{r}$ in the electric field of the nucleus becomes

$$\mathcal{V}(\mathbf{r})=-\frac{Ze^2}{4\pi\varepsilon_0}\int\frac{n(\mathbf{r}')}{|\mathbf{r}-\mathbf{r}'|}d\mathbf{r}'. \tag{6.2}$$

To evaluate integrals of the type appearing in Eqs. (6.1) and (6.2), we apply the cosine rule to express the relative distance $|\mathbf{r}-\mathbf{r}'|$ in terms of the radial distances r and r' with respect to the nuclear center of mass,

$$\frac{1}{|\mathbf{r}-\mathbf{r}'|}=\frac{1}{\sqrt{r'^2+r^2-2r'r\cos\vartheta}}. \tag{6.3}$$

Here ϑ is the angle enclosed by the directions $\hat{\mathbf{r}}$ and $\hat{\mathbf{r}}'$ as illustrated in Fig. 6.1. We first expand Eq. (6.3) in powers of the ratio $(r_</r_>)$, where $r_<=\min\{r,r'\}$ is the lesser and $r_>=\max\{r,r'\}$

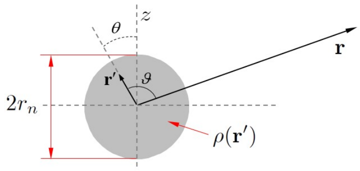


Figure 6.1: Nuclear charge-density distribution $\rho(\mathbf{r}') = Ze\,n(\mathbf{r}')$ with definition of the electron position $\mathbf{r}$ and nucleon position $\mathbf{r}'$ relative to the nuclear center. Note that ϑ is the angle enclosed by $\mathbf{r}$ and $\mathbf{r}'$, whereas θ is the angle of $\mathbf{r}'$ with respect to the z axis.

the greater of r and r'

$$\frac{1}{|\mathbf{r}-\mathbf{r}'|} = \frac{1}{r_>}\sum_{k=0}^{\infty}\left(\frac{r_<}{r_>}\right)^k P_k(\cos\vartheta). \tag{6.4}$$

The expansion is called the *multipole* expansion, with the subsequent terms referred to as the *monopole* ($k=0$), *dipole* ($k=1$), *quadrupole* ($k=2$), in general $2k$-*pole* contribution to the expansion. The expansion coefficients $P_k(u)$ are Legendre polynomials of degree k (cf. Appendix L.9). Only the monopole contribution is centrally symmetric. As only s electrons substantially penetrate the nucleus, only for s orbitals we meet conditions in which $r < r'$. For all other orbitals the penetration is negligible we may assume $r' \lll r$; i.e., $r_> = r$ and $r_< = r'$. In view of the orthogonality of the Legendre polynomials the s orbitals only sample the $k=0$ term and the expansion can be written in the form

$$\frac{1}{|\mathbf{r}-\mathbf{r}'|} = \frac{1}{r_>} + \frac{r'}{r^2}P_1(\cos\vartheta) + \frac{r'^2}{r^3}P_2(\cos\vartheta) + \cdots . \tag{6.5}$$

The relative angle ϑ can be expressed in terms of the absolute directions $\hat{\mathbf{r}}$ and $\hat{\mathbf{r}}'$ using the spherical harmonic *addition theorem* (L.56),

$$P_k(\cos\vartheta) = \frac{4\pi}{2k+1}\sum_{q=-k}^{k}(-1)^q Y_k^{-q}(\hat{\mathbf{r}})Y_k^q(\hat{\mathbf{r}}') \tag{6.6}$$

$$= \sum_{q=-k}^{k} Q_k^q(\hat{\mathbf{r}}')F_k^q(\hat{\mathbf{r}}) \equiv \mathbf{Q}^{(k)}\cdot\mathbf{F}^{(k)}, \tag{6.7}$$

where $Q_k^q(\hat{\mathbf{r}}')$ and $F_k^q(\hat{\mathbf{r}})$ are the standard components of the rank-k spherical tensors $\mathbf{Q}^{(k)}$ and $\mathbf{F}^{(k)}$, respectively, with $\mathbf{Q}^{(k)}$ representing the k-pole moment and $\mathbf{F}^{(k)}$ the field to which the moment couples. Using the multipole expansion the *potential energy* of an electron in the electric field of the nucleus can be written as the sum of a pure Coulomb contribution (point charge Ze at the nuclear center of mass) plus a series of correction terms,

$$\mathcal{V}(\mathbf{r}) = -\frac{Ze^2}{4\pi\varepsilon_0}\frac{1}{r} + \mathcal{H}_{\mathrm{NV}} + \mathcal{H}_{\mathrm{ED}} + \mathcal{H}_{\mathrm{EQ}} + \cdots . \tag{6.8}$$

The subsequent terms are

- the *electric-monopole* contribution

$$\mathcal{H}_{\mathrm{C}} = -\frac{Ze^2}{4\pi\varepsilon_0}\frac{1}{r}. \tag{6.9}$$

This operator provides the (unscreened) Coulomb interaction between a point-like nucleus and an electron at position $\mathbf{r}$. To elucidate the systematics of the multipole expansion we start by separating the $\mathbf{r}$ and $\mathbf{r}'$ dependence by using the addition theorem (6.6),

$$\mathcal{H}_{\mathrm{C}} = -\frac{e}{4\pi\varepsilon_0}\frac{1}{r}\sqrt{4\pi}Y_0^0(\hat{\mathbf{r}})M_0 = Q_0^0 F_0^0 \tag{6.10}$$

where the standard component

$$M_0 \equiv Q_0^0 = \int \rho(\mathbf{r})d\mathbf{r} = Ze \tag{6.11}$$

is the *nuclear electric-monopole moment*, with

$$\rho(\mathbf{r}) = Ze\, n(\mathbf{r}) \tag{6.12}$$

the *nuclear charge-density distribution.* For a given electronic state $|nlm\rangle$ the field is the scalar potential field of the electrons at the position of the nucleus,

$$E_{nlsjm} = \langle nlsjm|F_0^0|nlsjm\rangle = -\frac{e}{4\pi\varepsilon_0}\left\langle\frac{1}{r}\right\rangle_{nl}. \tag{6.13}$$

- the *nuclear volume correction*,

$$\mathcal{H}_{\mathrm{NV}} = -\frac{Ze^2}{4\pi\varepsilon_0}\int^{r_n}\frac{n(\mathbf{r}')}{r_>}d\mathbf{r}' + \frac{Ze^2}{4\pi\varepsilon_0}\frac{1}{r}, \tag{6.14}$$

with $r_> = r$ for $r' \leq r$ and $r_> = r'$ for $r' > r$. This correction accounts for the deviation from the pure $1/r$ field inside the nucleus. To estimate its importance we use the same approach as used in Section 4.1.2 for estimating the Darwin correction. We replace the nucleus by a homogeneously charged sphere of radius r_n and charge density $\varrho_0 = 3Ze/4\pi r_n^3$. Then, the integral evaluates to (see Problem 4.1)

$$\mathcal{H}_{\mathrm{NV}} = -\frac{Ze^2}{4\pi\varepsilon_0}\frac{1}{2r_n}\left[3 - \left(\frac{r}{r_n}\right)^2 - 2\frac{r_n}{r}\right]_{r<r_n}. \tag{6.15}$$

In calculating the correction for a given electronic orbital, $\Delta E_{\mathrm{NV}} = \langle nlm|\mathcal{H}_{\mathrm{NV}}|nlm\rangle$, we note that $r_n \ll a_0$. Therefore, he radial wavefunction can be replaced by its value in the origin and the correction becomes

$$\Delta E_{\mathrm{NV}} \simeq -\frac{Ze^2}{4\pi\varepsilon_0}\frac{1}{2r_n}R_{nl}^2(0)\int_0^{r_n}\left(3 - \frac{r^2}{r_n^2} - 2\frac{r_n}{r}\right)r^2dr = \frac{1}{4\pi\varepsilon_0}\frac{Z}{10}\frac{e^2r_n^2}{a^3}\tilde{R}_{nl}^2(0). \tag{6.16}$$

- the *electric-dipole interaction*,

$$\mathcal{H}_{\mathrm{ED}} = -\frac{Ze^2}{4\pi\varepsilon_0}\frac{1}{r^2}\int r'P_1(\cos\vartheta)n(\mathbf{r}')d\mathbf{r}'. \tag{6.17}$$

This integral *averages to zero* because the electric-dipole moment (EDM) vanishes.[1] To demonstrate this we separate the $\mathbf{r}$ and $\mathbf{r}'$ dependence using the addition theorem (6.6),

$$\mathcal{H}_{\mathrm{ED}} = -\frac{e}{4\pi\varepsilon_0}\frac{1}{r^2}\sqrt{\frac{4\pi}{3}}\sum_{q=-1}^{1}(-1)^q Y_1^{-q}(\hat{\mathbf{r}})Q_1^q, \tag{6.18}$$

---

[1] More generally all *odd-k* electric-multipole moments vanish for similar reasons.

where

$$Q_1^q \equiv \int r\sqrt{4\pi/3}\,Y_1^q(\hat{\mathbf{r}})\rho(\mathbf{r})d\mathbf{r} \tag{6.19}$$

stands for the standard components of the *nuclear electric-dipole tensor.* Since the parity of $Y_1^q(\hat{\mathbf{r}})$ is odd, see Eq. (L.53), the Q_1^q, with $-1 \leq q \leq 1$, average to zero unless the parity of the nuclear charge-density distribution is also odd. The latter means that the center of charge is shifted with respect to the center of mass, which is incompatible with the electromagnetic and strong forces among the nucleons.[1] The weak interaction is not parity conserving but too weak to give rise to a measurable permanent nuclear electric-dipole moment.

A good measure for the strength of the electric-dipole tensor is the *electric-dipole moment*,

$$D \equiv Q_1^0 = \int r\cos\theta\,\rho(\mathbf{r})d\mathbf{r}, \tag{6.20}$$

where θ (not to be confused with ϑ) is the polar angle with respect to the direction of axial symmetry. Since the parity of $r\cos\theta$ is odd, the dipole moment averages to zero unless the parity of the nuclear charge distribution is also odd.

- the *electric quadrupole interaction*,

$$\mathcal{H}_{\mathrm{EQ}} = -\frac{Ze^2}{4\pi\varepsilon_0}\frac{1}{r^3}\int r'^2 P_2(\cos\vartheta)n(\mathbf{r}')d\mathbf{r}'. \tag{6.21}$$

Using the addition theorem (6.6) this expression can be rewritten in the form

$$\mathcal{H}_{\mathrm{EQ}} = -\frac{e}{4\pi\varepsilon_0}\frac{1}{r^3}\sqrt{\frac{4\pi}{5}}\sum_{q=-2}^{2}(-1)^q Y_2^{-q}(\hat{\mathbf{r}})Q_2^q, \tag{6.22}$$

where the Q_2^q represent the spherical components of a rank 2 tensor, the *nuclear quadrupole tensor.* For a (unit-normalized) *classical* charge distribution $n(\mathbf{r})$ the component Q_2^q is of form

$$Q_2^q \equiv \int r^2\sqrt{4\pi/5}Y_2^q(\hat{\mathbf{r}})\rho(\mathbf{r})d\mathbf{r}, \tag{6.23}$$

with $\rho(\mathbf{r})$ being the the nuclear charge-density distribution (6.12). The *quadrupole moment* of such a classical distribution $\rho(\mathbf{r})$ is defined as

$$Q \equiv \int r^2(3\cos^2\theta - 1)\rho(\mathbf{r})d\mathbf{r}, \tag{6.24}$$

where the angle θ (not to be confused with ϑ) is the polar angle with respect to the direction of axial symmetry. Comparing Eqs. (6.23) and (6.24) we find

$$Q_2^0 = \tfrac{1}{2}Q. \tag{6.25}$$

In Fig. 6.2*a* we show three examples of classical bodies, two with and one without a quadrupolar deformation. In all three cases the symmetry axis is chosen along the z direction. The quadrupole moment is positive for shapes elongated along the axial direction; i.e., for cigar-like (prolate) shapes. It is negative for axially compressed spheres; i.e., for pancake-like (oblate) shapes. Spherical bodies have no (i.e., zero) quadrupole moment.

$$\Delta E = -\frac{e}{4\pi\varepsilon_0}\frac{1}{r^3}\sum_{q=-2}^{2}(-1)^q\sqrt{4\pi/5}\,Y_2^{-q}(\hat{\mathbf{r}})Q_2^q = \sum_{q=-2}^{2}Q_2^qF_2^q$$

---

[1] Here we pass by on the possibility that the nucleons carry an EDM. Thus far these have not been observed but EDM searches are important in search for physics beyond the standard model [38, 40, 116].

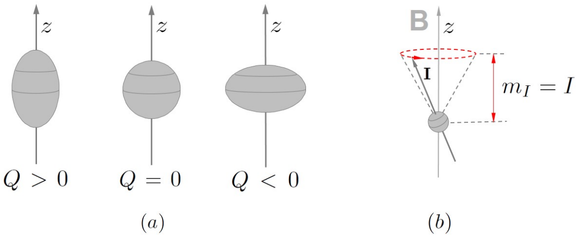

Figure 6.2: Nuclei with spins $I > 1/2$ can have an electric quadrupole moment: a.) sketch of a classical charge distribution spinning along the direction of axial symmetry. The quadrupole moment Q can be determined by measuring the aspect ratio of the principal axes. Spherical nuclei have no quadrupole moment ($Q = 0$). The quadrupole moment is defined as positive ($Q > 0$) for shapes elongated along the axial direction (prolate); it is negative ($Q < 0$) for pancake-like (oblate) deformations. b.) Quantum mechanically nuclei have angular momentum in their ground state (the nuclear spin I) and it is impossible to fully align the spin along the quantization axis. To measure the quadrupole moment we have to polarize the nucleus in the state of maximum spin projection $m_I = I$ and determine the expectation value of the quadrupole operator.

where

$$F_2^q = -\frac{e}{4\pi\varepsilon_0}\frac{1}{r^3}(-1)^q\sqrt{4\pi/5}\,Y_2^{-q}(\hat{\mathbf{r}})$$

$$\langle nlsjm|F_2^q|nlsjm\rangle = -\frac{e}{4\pi\varepsilon_0}(-1)^{j+m+q}\langle r^{-3}\rangle_{nl}\langle lsj||\sqrt{4\pi/5}\,Y_2(\hat{\mathbf{r}})||lsj\rangle\begin{pmatrix} j & 2 & j \\ m & q & -m \end{pmatrix} \tag{6.26}$$

This immediately shows that $\langle nlsjm|F_2^q|nlsjm\rangle = 0$

$$\begin{pmatrix} j & 2 & j \\ m & q & -m \end{pmatrix} = 0$$

if $q \neq 0$ and for $2j < 2$

6.1.1 Nuclear quadrupole moment in quantum mechanics

The quantization of the Coulomb interaction was straightforward, we simply had to replace the dynamical variable r by the operator $\underline{r}$. This enabled us to obtain the nuclear volume correction (6.16) without using any information about the internal structure of the nucleus. The quantization of electric quadrupole interaction is more demanding in this respect because the quadrupole moment cannot be observed without at least orienting the nucleus and for this we need information about the nuclear state. Fortunately, in atomic physics we are dealing with nuclei in their ground state and to understand the electronic structure all we need to know is the state of the nuclear spin $\mathbf{I}$. Without control over the spin we cannot orient the nucleus and the observable quadrupole moment is zero. The nuclear spin represents the *total* angular momentum of the nucleus. Therefore, without addressing the nuclear structure it will be impossible to trace down the origin of this spin. Interestingly, this lack of information does not prevent us from establishing the nuclear quadrupole moment (or higher multipole moments) because (for a free nucleus) the total angular momentum offers the only reference direction of the nucleus that can be conserved in time. Although it is impossible to fully align the vector $\mathbf{I}$ along the z direction (see Fig. 6.2b), we can polarize the nucleus in the state of maximum spin projection, $|\alpha; I, m_I\rangle = |\alpha; I, I\rangle$, and use the quantization axis as the only available reference axis to define the nuclear moments. Here α stands for all "other" quantum numbers of the nucleus. As these have to be invariant under rotation of the nucleus about the quantization axis, they have to correspond to the quantum mechanical *eigenvalues* of operators that commute with both $\mathbf{I}^2$ and I_z. For the electric quadrupole moment this leads us to search for a spherical tensor operator of rank 2, the *quadrupole operator* Q_2, of which the standard components Q_2^q transform like the $Y_2^q(\hat{\mathbf{r}})$ and satisfy the commutation relations (K.3) with respect to the standard components of $\mathbf{I}$. In particular, the $q=0$ standard component Q_2^0 matches our criteria for the quadrupole moment operator

$$Q_2^0 \equiv \sqrt{4\pi/5}\, r^2 Y_2^0(\hat{\mathbf{r}}) \tag{6.27}$$

because it commutes with both $\mathbf{I}^2$ and I_z. By analogy with Eq. (6.23) the *nuclear quadrupole moment* Q is defined by

$$\langle \alpha; I, I|Q_2^0|\alpha; I, I\rangle \equiv \tfrac{1}{2}Q. \tag{6.28}$$

The prefactor $\frac{1}{2}$ serves to conform to the convention (6.24) used for the classical quadrupole moment. Interestingly, although we did not introduce explicit expressions for the components Q_2^q, we can already find out a lot about their properties because we know that they have to transform like one of the standard components of a rank 2 spherical tensor operator; i.e., they have to satisfy the Wigner-Eckart theorem (K.23),

$$\langle \alpha I m'|Q_2^q|\alpha I m\rangle = (-1)^{I+m_I'}\langle \alpha I||Q_2||\alpha I\rangle \begin{pmatrix} I & 2 & I \\ m & q & -m' \end{pmatrix}. \tag{6.29}$$

This theorem holds for any value of m and m', and (in view of our current interest in the quadrupole moment) in particular for the case $m = m' = I$ and $q = 0$. Using Eq. (J.19a), we obtain

$$\tfrac{1}{2}Q = \langle \alpha, I, I|Q_2^0|\alpha, I, I\rangle = (-1)^{2I}\langle \alpha I||Q_2||\alpha I\rangle \sqrt{\frac{I(2I-1)}{(I+1)(2I+3)\,(2I+1)}}. \tag{6.30}$$

With this expression we immediately establish that $Q = 0$ unless $I \geq 1$; i.e., nuclei with spin $I = 0$ or $I = \frac{1}{2}$ *cannot* have a quadrupole moment in quantum mechanics. Furthermore, it can serve to eliminate the unknown reduced matrix element $\langle \alpha I||Q_2||\alpha I\rangle$ from Eq. (6.30). Actually, this procedure amounts to replacing one unknown quantity by another unknown quantity: the quadrupole moment Q,

$$\langle \alpha I||Q_2||\alpha I\rangle = (-1)^{2I}\frac{Q}{2I(2I-1)}\sqrt{(2I-1)I(I+1)(2I+1)(2I+3)}, \tag{6.31}$$

with $Q/2I(2I-1) = 0$ for $I \leq \frac{1}{2}$. The quadrupole moment covers all nuclear properties except those related to the nuclear spin (in particular it contains the radial integral over the nuclear charge distribution). The strategy is clear: even in the absence of a theory for the nuclear quadrupole moment we can search for its signature in experiments and determine Q empirically. Some numerical values are listed in Table 5.1.

Substituting Eq. (6.31) into (6.30) we obtain a closed expression for the standard components of the quadrupole moment,

$$\langle \alpha I m_I'|Q_2^q|\alpha I m_I\rangle = (-1)^{m_I'-I}\frac{Q}{2I(2I-1)}\sqrt{(2I-1)I(I+1)(2I+1)(2I+3)}\begin{pmatrix} I & 2 & I \\ m_I & q & -m_I' \end{pmatrix}, \tag{6.32}$$

with $Q/2I(2I-1) = 0$ for $I \leq \frac{1}{2}$. At this point we can calculate all matrix elements of the type (6.32) and it should be possible to distill from this expressions for the operators Q_2^q. As a first example we focus again on the operator Q_2^0 for which the matrix elements are only nonzero if $m_I = m_I'$. Using Eq. (J.19a) we obtain

$$\langle I m_I|Q_2^0|I m_I\rangle = Q\frac{3m_I^2 - I\,(I+1)}{2I(2I-1)}, \tag{6.33}$$

with $Q/2I(2I-1)=0$ for $I \le \frac{1}{2}$. The operator that satisfies this property is easily recognized; for a spin-I nucleus we have

$$Q_2^0 = \frac{Q}{2I(2I-1)}(3I_z^2 - \mathbf{I}^2). \tag{6.34}$$

with $Q/2I(2I-1)=0$ for $I \le \frac{1}{2}$. It is readily verified that Q_2^0 commutes with $\mathbf{I}^2$ and satisfies the commutation relations (K.3); i.e., Q_2^0 indeed represents a standard component of the spherical tensor operator Q_2. Note further that Q_2^0 is hermitian and since I_z and $\mathbf{I}^2$ commute with the fine-structure Hamiltonian it is also an observable. With Eq. (6.34) we established that the operator Q_2^0 can be expressed in terms of the components of the vector operator $\mathbf{I}$. The rank 2 tensor operators Q_2^q transform like the Y_2^m, just like vector operators (rank 1 tensors) transform like Y_1^m. Thus, comparing with Eqs. (L.55) or (5.31) we immediately find relations for $Q_2^{\pm1}$ and $Q_2^{\pm2}$,

$$Q_2^{\pm1} = \mp\frac{Q}{2I(2I-1)}\left(I_\pm I_z + I_z I_\pm\right)\sqrt{3/2} \tag{6.35}$$

$$Q_2^{\pm2} = \frac{Q}{2I(2I-1)} I_\pm I_\pm \sqrt{3/2}, \tag{6.36}$$

with $Q/2I(2I-1)=0$ for $I \le \frac{1}{2}$. These expressions also satisfy the commutation relations (K.3) and we easily verify that Q_2^q and Q_2^{-q} are hermitian conjugates. Note the similarity with Eqs. (5.31).

The electric quadrupole field of the electrons at position of the nucleus is also given by a spherical tensor operator of rank 2,

$$q_2^q \equiv \sqrt{4\pi/5}\, r^{-3} Y_2^q(\hat{\mathbf{r}}) \tag{6.37}$$

since the $Y_2^q(\hat{\mathbf{r}})$ and satisfy the commutation relations (K.3) with respect to the standard components of $\mathbf{L}$. This is explicitly shown in Eqs. (K.17). In particular, the $q=0$ standard component q_2^0 matches our criteria for the quadrupole moment operator

$$q_2^0 \equiv \sqrt{4\pi/5}\, r^{-3} Y_2^0(\hat{\mathbf{r}}) \tag{6.38}$$

because it commutes with both $\mathbf{L}^2$ and L_z. By analogy with Eq. (6.23) the *nuclear quadrupole moment* Q is defined by

$$\langle\alpha; I, I|q_2^0|\alpha; I, I\rangle \equiv \tfrac{1}{2}q. \tag{6.39}$$

The prefactor $\frac{1}{2}$ is again conventional. Although we did not introduce explicit expressions for the components q_2^q, we can already find out a lot about their properties because we know that they have to transform like one of the standard components of a rank 2 spherical tensor operator; i.e., they have to satisfy the Wigner-Eckart theorem (K.23),

$$\langle nlm'|q_2^q|nlm\rangle = (-1)^{l+m'}\langle r^{-3}\rangle_{nl}\langle l||\sqrt{4\pi/5}\,Y^{(2)}(\hat{\mathbf{r}})||l\rangle\begin{pmatrix} l & 2 & l \\ m & q & -m'\end{pmatrix}. \tag{6.40}$$

Here we separated the radial from the angular part. The angular part can be determined by comparing with the Gaunt integral. In this way we obtain - see Section K.3.3

$$\langle nlm'|q_2^q|nlm\rangle = (-1)^{l+m'+1}\langle r^{-3}\rangle_{nl}\sqrt{\frac{l(l+1)(2l+1)}{(2l+3)(2l-1)}}\begin{pmatrix} l & 2 & l \\ m & q & -m'\end{pmatrix}.$$

$$\langle nlm'|q_2^0|nlm\rangle = (-1)^{2(l+m')+1}\langle r^{-3}\rangle_{nl}\frac{3m^2 - l(l+1)}{(2l+3)(2l-1)}.$$

In particular, this theorem hold for the case $m = m' = l$ and $q = 0$. Using Eq. (J.19a), we obtain

$$\tfrac{1}{2}q = \langle nll|q_2^0|nll\rangle = \langle r^{-3}\rangle_{nl}\frac{l(l+1)}{(2l+3)(2l-1)}.$$

6.1.2 Electric quadrupole interaction

Using the quadrupole operators the electric quadrupole interaction (6.21) takes the form

$$\mathcal{H}_{\mathrm{EQ}} = -\frac{Ze^2}{4\pi\varepsilon_0}\frac{1}{r^3}\sqrt{\frac{4\pi}{5}}\sum_{q=-2}^{2}(-1)^q Y_2^{-q}(\hat{\mathbf{r}})Q_2^q. \tag{6.41}$$

This Hamiltonian represents the interaction between the *electric quadrupole* fields of the nuclear and the electronic charge distributions. The nuclear electric quadrupole operator given by the rank 2 tensor

$$\mathrm{T}_1^{(2)}(\hat{\mathbf{r}}') = Ze\sqrt{\frac{4\pi}{5}}Y_2(\hat{\mathbf{r}}').$$

Likewise, the electric quadrupole operator for the electronic charge distribution is given by the rank 2 tensor

$$\mathrm{T}_2^{(2)}(\hat{\mathbf{r}}) = -e\frac{1}{r^3}\sqrt{\frac{4\pi}{5}}Y_2(\hat{\mathbf{r}}).$$

Thus, using first order perturbation theory for a hyperfine state of given $nlsjIF$, the quadrupole shift is given by

$$\Delta E_{\mathrm{EQ}}(n\,^{2s+1}L_j) = \langle nlsjIFM_F|\mathcal{H}_{\mathrm{EQ}}|nlsjIFM_F\rangle. \tag{6.42}$$

The electric quadrupole interaction is given by

$$\mathcal{H}_{\mathrm{EQ}} = -\frac{Ze^2}{4\pi\varepsilon_0}\frac{1}{r^3}\sqrt{\frac{4\pi}{5}}\sum_{q=-2}^{2}(-1)^q Y_2^{-q}(\hat{\mathbf{r}})Q_2^q. \tag{6.43}$$

Thus, using first order perturbation theory for a hyperfine state of given $nlsjIF$, the quadrupole shift is given by

$$\Delta E_{\mathrm{EQ}}(n\,^{2s+1}L_j) = \langle nlsjIFM_F|\mathcal{H}_{\mathrm{EQ}}|nlsjIFM_F\rangle. \tag{6.44}$$

$$\Delta E_{\mathrm{EQ}}(n\,^{2s+1}L_j) = \frac{1}{4}\mathcal{B}_{\mathrm{hfs}}\frac{3K(K+1) - 4I(I+1)j(j+1)}{2I(2I-1)j(2j-1)}, \tag{6.45}$$

where $K \equiv F(F+1) - j(j+1) - I(I+1)$ is a shorthand notation and

$$\mathcal{B}_{\mathrm{hfs}} = -\frac{2j-1}{2j+2}\frac{e^2}{4\pi\varepsilon_0 a^3}Q\langle\rho^{-3}\rangle_{nl}. \tag{6.46}$$

For given n, l, s and I our interest concerns matrix elements of the type

$$\langle nlsj'IF'M'|\mathcal{H}_{\mathrm{EQ}}|nlsjIFM\rangle = -\frac{Ze^2}{4\pi\varepsilon_0}\frac{1}{r^3}\sqrt{\frac{4\pi}{5}}\sum_{q=-2}^{2}(-1)^q\langle nlsj'IF'M'|Y_2^{-q}(\hat{\mathbf{r}})Q_2^q|nlsjIFM\rangle. \tag{6.47}$$

Separating the matrix elements into two parts (by inserting a complete set of angular momentum states) we obtain

$$\langle nlsj'IF'M'|\mathcal{H}_{\mathrm{EQ}}|nlsjIFM\rangle =$$
$$= \frac{e^2}{4\pi\varepsilon_0}\frac{1}{a^3}\sum_{F'',M''}\sum_{q=-2}^{2}(-1)^q\langle\rho^{-3}\rangle_{nl}\langle nlsj'IF'M'|q_2^q|nlsjIF''M''\rangle\langle jIF''M''|ZQ_2^q|jIFM\rangle, \tag{6.48}$$

where

$$ZQ_2^q \equiv Z\sqrt{4\pi/5}\,\rho'^2 Y_2^q(\hat{\mathbf{r}}') \tag{6.49}$$

is the nuclear electric quadrupole operator and

$$q_2^q \equiv -\sqrt{4\pi/5}\,\rho^{-3}Y_2^q(\hat{\mathbf{r}}) \tag{6.50}$$

electric quadrupole operator for the electronic orbital (in atomic units). Applying to each of these parts the Wigner-Eckart theorem for *spherical* tensor operators, see Eq. (K.24), we obtain

$$\begin{aligned}\langle nlsj'IF'M'|\mathcal{H}_{\mathrm{EQ}}|nlsjIFM\rangle &= \frac{e^2}{4\pi\varepsilon_0}\frac{1}{a^3}\sum_{F'',M''}\sum_{q=-2}^{2}(-1)^{q+F'-M'+F''-M''}\\ &\langle j'IF'||q_2||jIF''\rangle\langle jIF''||Q_2||jIF\rangle\begin{pmatrix}F' & 2 & F''\\ -M' & -q & M''\end{pmatrix}\begin{pmatrix}F'' & 2 & F\\ -M'' & q & M\end{pmatrix}.\end{aligned} \tag{6.51}$$

In view of the $3j$ projection rule we have $q = M''-M'$ and $(-1)^{q+F'-M'+F''-M''} = (-1)^{F'+F''-2M'}$. Adding and subtracting F' in the exponent and noting that $2(F'-M')$ is always even, the matrix element becomes, after rearrangement of the first $3j$ symbol (exchange two columns and apply the sign rule in the lower row),

$$\begin{aligned}\langle nlsj'IF'M'|\mathcal{H}_{\mathrm{EQ}}|nlsjIFM\rangle &= \frac{e^2}{4\pi\varepsilon_0}\frac{1}{a^3}\sum_{F''}(-1)^{F''-F'}\\ &\langle j'IF'||q_2||jIF''\rangle\langle jIF''||Q_2||jIF\rangle\sum_{M''=-F''}^{F''}\sum_{q=-2}^{2}\begin{pmatrix}F'' & 2 & F'\\ -M'' & q & M'\end{pmatrix}\begin{pmatrix}F'' & 2 & F\\ -M'' & q & M\end{pmatrix}.\end{aligned} \tag{6.52}$$

Applying the $3j$ orthogonality relation (J.6) we find that F and M are conserved by the quadrupole coupling and the matrix element simplifies to

$$\begin{aligned}&\langle nlsj'IF'M'|\mathcal{H}_{\mathrm{EQ}}|nlsjIFM\rangle =\\ &\quad= \frac{e^2}{4\pi\varepsilon_0}\frac{1}{a^3}\sum_{F''}(-1)^{F''-F'}\langle j'IF'||q_2||jIF''\rangle\langle jIF''||Q_2||jIF\rangle\frac{\delta_{F,F'}\delta_{M,M'}}{2F+1}.\end{aligned} \tag{6.53}$$

Since q_2 acts in the subspace of j and Q_2 acts in the subspace of I we can apply the expression (K.62) for *repeated reduction*,

$$\langle jIF''||Q_2||jIF\rangle = (-1)^{F+I+j}\langle I||Q_2||I\rangle\sqrt{(2F''+1)(2F+1)}\begin{Bmatrix}I & F'' & j\\ F & I & 2\end{Bmatrix}, \tag{6.54}$$

$$\langle j'IF'||q_2||jIF''\rangle = (-1)^{F''+j''+I}\langle lsj'||q_2||lsj''\rangle\sqrt{(2F'+1)(2F''+1)}\begin{Bmatrix}j' & F' & I\\ F'' & j & 2\end{Bmatrix}. \tag{6.55}$$

Substituting these equations into Eq. (6.53) we obtain

$$\begin{aligned}\langle nlsj'IF'M'|\mathcal{H}_{\mathrm{EQ}}|nlsjIFM\rangle &= \frac{e^2}{4\pi\varepsilon_0}\frac{1}{a^3}(-1)^{F+F''+j+j''+2I}\\ &\langle lsj'||q_2||lsj\rangle\langle I||Q_2||I\rangle\delta_{F,F'}\delta_{M,M'}\sum_{F''}(-1)^{F''}(2F''+1)\begin{Bmatrix}j' & F & I\\ F'' & j & 2\end{Bmatrix}\begin{Bmatrix}I & F'' & j\\ F & I & 2\end{Bmatrix}.\end{aligned} \tag{6.56}$$

Next we rearrange the $6j$symbols to apply the sum rule (J.34)

$$\begin{aligned}\langle nlsj'IF'M'|\mathcal{H}_{\mathrm{EQ}}|nlsjIFM\rangle &= \frac{e^2}{4\pi\varepsilon_0}\frac{1}{a^3}(-1)^{F+j+I}\\ &\langle lsj'||q_2||lsj''\rangle\langle I||Q_2||I\rangle\delta_{F,F'}\delta_{M,M'}\sum_{F''}(-1)^{F''+j'+I}(2F''+1)\begin{Bmatrix}F & I & j'\\ j & 2 & F''\end{Bmatrix}\begin{Bmatrix}I & j & F''\\ F & 2 & I\end{Bmatrix}.\end{aligned} \tag{6.57}$$

Thus we arrive at

$$\langle nlsj'IF'M'|\mathcal{H}_{\mathrm{EQ}}|nlsjIFM\rangle = \\ = \frac{e^2}{4\pi\varepsilon_0}\frac{1}{a^3}(-1)^{F+j+I}\langle lsj'||q_2||lsj\rangle\langle I||Q_2||I\rangle \begin{Bmatrix} j & I & F \\ I & j' & 2 \end{Bmatrix} \delta_{F,F'}\delta_{M,M'}. \quad (6.58)$$

asd

$$\langle nl|\rho^{-3}Y_2^{-q}(\hat{\mathbf{r}})|nl\rangle = \langle\rho^{-3}\rangle_{nl}\int Y_2^{-q}(\hat{\mathbf{r}})|Y_l^m(\hat{\mathbf{r}})|^2 d\hat{\mathbf{r}} = \frac{l(l+1)-3m^2}{(2l+3)(2l-1)}$$

7

Helium-like atoms

Once we have more than one electron around the nucleus the Hamiltonian for the electronic motion rapidly becomes more complicated. Aside from the attraction by the nuclear charge we have to account for the electrostatic repulsion among the electrons. At a more refined level we not only have to deal with the *spin-orbit interaction* between the spin and the orbit of the individual electrons but also with the interaction of the spin of one electron with the orbit of the other electrons; i.e., the *spin-other-orbit interaction*. Likewise we have *magnetic-dipole interaction* between the spins of the various electrons and *magnetic-orbit-orbit interaction* between the orbital moments of the electrons. Needless to say that even a glance at the Hamiltonian shows that we are facing a formidable task.

Fortunately a lot can be understood about many-electron atoms without pursuing the precision possible for hydrogen. Actually, bearing in mind that the electrostatic interaction is by far the strongest interaction in the atom, it is pointless to consider refinements before we have a theory at hand in which the electronic charge is distributed over the atom in the best possible way. If the electronic wavefunction is known this requirement is of course implicitly satisfied but, unfortunately, for atoms with more than one electron exact analytical solutions cannot be obtained. We shall find that at a given stage we have to rely on some semiclassical approximation to obtain a result for the electrostatic energy. Furthermore, the distribution of the charge is strongly affected by a quantum phenomenon completely absent in hydrogenic atoms: *exchange*. The exchange phenomenon is not captured in the Hamiltonian but has to be added to the theory as a completely new element. It strongly affects all many-electron systems. In atoms it tends to align the electron spins in a parallel fashion, in molecules anti-parallel, in many-body systems like gases and solids it gives rise to various forms of magnetism.

Exchange emerges as an effective electrostatic interaction resulting from kinematic correlations between the electrons. These correlations have a purely quantum mechanical origin and only occur between *identical particles*. As these are *indistinguishable* the Hamiltonian is manifestly invariant under exchange of two of these particles [31]. So the exchange operator commutes with the Hamiltonian which implies that the symmetry under exchange is a conserved quantity (see Appendix F.2.4). The eigenstates of the exchange operator are either *symmetric* or *antisymmetric* [31]. Importantly, linear combinations of these (so called mixed statistics) are *not* observed. To distinguish between the two cases the particles are referred to as *bosons* (symmetric) or *fermions* (antisymmetric) [31]. As the quantum correlations affect the probability of occupation of the single particle states, their presence demands new statistics, *quantum statistics*, different for bosons and fermions [31]. Electrons behave like fermions. This was discovered by Wolfgang Pauli, when he realized that the magnetic fine structure of the optical spectra of the elements could be explained by excluding atomic states in which more than one electron in a given spin state would occupy a given atomic orbital. He formulated this observation in his famous *exclusion principle*: double occupation of a given single-electron state has to be excluded [81]. At a more abstract level this is a consequence of *Fermi-Dirac statistics* (short: Fermi statistics) [31]. In contrast, in *Bose-Einstein statistics* (short:

Bose statistics) double/multiple occupation is possible and even favored. Bose statistics plays no role in theoretical descriptions of atoms simply because the electrons are fermions and the atom only has a single nucleus. By studying the helium atom we meet the phenomenology essential for the conception of the Pauli principle.

7.1 Heliogenic atoms

To introduce the physics of atoms with more than one electron we turn to the element helium, the archetype of the *heliogenic* atoms. The notion *heliogenic* refers to atomic systems with *exactly two* elementary charges orbiting about the nucleus. Aside from the helium isotopes ^{3}He and ^{4}He, also the negative ion of hydrogen, H$^-$, and the positive ions Li$^+$, Be^{++}, etc., as well as exotic atoms like muonic helium belong to this class.

We start by calculating the *principal structure* of a heliogenic atom/ion with two electrons. In constructing the Hamiltonian, the essential difference with the hydrogenic case is that we have to account for the electrostatic repulsion between the electrons,

$$\mathcal{H} = \sum_{i=1,2} \left(-\frac{\hbar^2}{2m_e} \boldsymbol{\nabla}_i^2 - \frac{Ze^2}{4\pi\varepsilon_0 r_i} \right) + \frac{e^2}{4\pi\varepsilon_0 r_{12}}. \tag{7.1}$$

The first term gives the summation over the Schrödinger Hamiltonians of the two electrons orbiting in the Coulomb field of a nucleus of charge Ze. The second term represents the electrostatic repulsion, where ε_0 is the *electric permittivity of vacuum*, m_e the rest mass of the electron, $\mathbf{r}_i$ the position of electron i relative to the atomic nucleus and $r_{12} = |\mathbf{r}_1 - \mathbf{r}_2|$ the inter-electronic distance. Small corrections related to fine- and hyperfine structure are not considered for the time being.

Before starting the actual work we have a look at the symmetry properties of $\mathcal{H}$. Like the Schrödinger Hamiltonian also $\mathcal{H}$ is invariant under space inversion, which means that the parity of the electronic states is conserved in time (see Appendix F.2.4). As $\mathcal{H}$ is also invariant under rotation of the spatial coordinates about the origin, also the total orbital angular momentum $\mathbf{L} = \boldsymbol{l}_1 + \boldsymbol{l}_2$ and its projection L_z are conserved quantities,

$$[\mathbf{L}^2, \mathcal{H}] = 0 \quad \text{and} \quad [L_z, \mathcal{H}] = 0. \tag{7.2}$$

In other words, L and M_L are good quantum numbers, also in the presence of the repulsion term in the Hamiltonian. The commutation of $\mathbf{L}^2$ and L_z with the repulsion term is demonstrated explicitly in Problem 7.1.

To calculate the energy levels of the atom we start by crudely neglecting the electrostatic repulsion term of Eq. (7.1). In this way we regain a structure similar to that of the hydrogen atom. We obtain the hydrogenic eigenstates $|nlm_l\rangle$ and the eigenvalues are given by

$$E_n = -\alpha^2 m_e c^2 \frac{Z^2}{2n^2} = -hcR_\infty \frac{Z^2}{n^2}. \tag{7.3}$$

Here n, l, m_l are the quantum numbers of the principal atomic structure and R_∞ is the *Rydberg constant* for an electron bound to a nucleus of infinite mass. As, in the given approximation, the Hamiltonian for the electron pair does not contain the Coulomb coupling between the orbital motions of the electrons the pair wavefunction $\psi_a(\mathbf{r}_1, \mathbf{r}_2) = (\mathbf{r}_1, \mathbf{r}_2|u, v)$ can be represented by products of two hydrogenic states $|u\rangle = |nlm_l\rangle$ and $|v\rangle = |n'l'm_{l'}\rangle$,

$$\psi_a(\mathbf{r}_1, \mathbf{r}_2) = \varphi_u(\mathbf{r}_1)\, \varphi_v(\mathbf{r}_2). \tag{7.4}$$

The corresponding energy of the *non-interacting* electronic pair follows from solving the Schrödinger equation for the noninteracting hamiltonian

$$\mathcal{H}_0 = \sum_{i=1,2} \left(-\frac{\hbar^2}{2m_e} \boldsymbol{\nabla}_i^2 - \frac{Ze^2}{4\pi\varepsilon_0 r_i} \right). \tag{7.5}$$

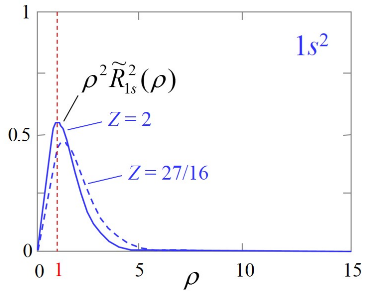

Figure 7.1: Radial distribution function for the electrons in the ground state of the helium atom. The drawn line corresponds to a $1s^2$ configuration without interaction. The dashed line shows the effect of inflation of the charge distribution caused by the Coulomb repulsion. The curve corresponds to an effective atomic number $Z_{1s} = 27/16$.

The solutions are given by

$$E_a^{(0)} = E_{n_u} + E_{n_v} = -hcR_\infty \left(\frac{Z^2}{n_u^2} + \frac{Z^2}{n_v^2} \right), \tag{7.6}$$

which is simply the sum of the energies of the individual electrons in the Coulomb field of the bare nucleus. For example, the helium atom in its electronic ground state consists of a doubly charged nucleus ($Z = 2$) and two equivalent electrons in the *configuration* $1s^2$, both occupying the $|u\rangle = |nlm\rangle = |100\rangle$ orbital of *hydrogenic helium* shown as the solid line in Fig. 7.1. With Eq. (7.6) we calculate for the total energy of the electronic ground state

$$E_{1s^2}^{(0)} = -8hcR_\infty \qquad (Z = 2,\ n = 1), \tag{7.7}$$

which is twice the energy of *hydrogenic helium*.

Problem 7.1. Show that for the orbital angular momentum $\mathbf{L} = \boldsymbol{l}_1 + \boldsymbol{l}_2$, where $\boldsymbol{l}_\nu = -i\hbar(\mathbf{r}_\nu \times \boldsymbol{\nabla}_\nu)$ with $\nu \in \{1, 2\}$, the following commutation relations hold:

$$[L_z, 1/r_{12}] = 0 \quad \text{and} \quad [\mathbf{L}^2, 1/r_{12}] = 0,$$

where $r_{12} = |\mathbf{r}_1 - \mathbf{r}_2|$ is the inter-electronic distance.

Solution. The first commutation relation will be derived for the more general case of an arbitrary cartesian component, $[L_i, 1/r_{12}] = 0$ with $i \in \{x, y, z\}$; i.e., $[\mathbf{L}, 1/r_{12}] = 0$. Since $\mathbf{L}$ is a linear differential operator acting on the variables $\mathbf{r}$ and $\mathbf{r}'$ we find

$$[\mathbf{L}, 1/r_{12}]\psi = \mathbf{L}(\psi/r_{12}) - (1/r_{12})\mathbf{L}\psi = \psi\mathbf{L}(1/r_{12}) = \psi\,(\boldsymbol{l}_1 + \boldsymbol{l}_2)\,(1/r_{12}) = 0,$$

where we used $\boldsymbol{l}_1(1/r_{12}) = -\boldsymbol{l}_2(1/r_{12})$ as follows with Eq. (N.21). The second commutation relation follows with the aid of the first relation. Using the Einstein summation convention we find

$$[\mathbf{L}^2, 1/r_{12}] = [L_iL_i, 1/r_{12}] = [L_i, 1/r_{12}]L_i + L_i[L_i, 1/r_{12}] = 0. \qquad \square$$

7.1.1 Electrostatic repulsion versus screening

Not surprisingly the approximation of non-interacting electrons is rather poor. Electrostatic repulsion tends to inflate the $1s$ orbitals as illustrated by the dashed line in Fig. 7.1. This reduces the *binding energy* of the electrons because the average distance to the nucleus increases. Another way to look at this is that one electron will partly *screen* the nuclear charge for the other electron. This effectively reduces the nuclear charge Ze, which also results in a reduction of the binding energy.

Using Eq. (7.6), i.e., without the interaction term, we calculate for the *first ionization energy* of the atom 54.4 eV (4 Rydberg), whereas the measured value is only 24.6 eV. Clearly, the screening is important.

To calculate the effect of screening we turn to perturbation theory; it may be that for this purpose the repulsive term is not sufficiently small but at least it will reveal the trend. We first make the Hamiltonian dimensionless by multiplying Eq. (7.1) with $m_e a_0^2/\hbar^2 = 1/\left(2hcR_\infty\right)$, thus switching to Hartree atomic units,

$$\mathcal{H} = \mathcal{H}_0 + \frac{1}{\rho_{12}}, \tag{7.8}$$

where

$$\mathcal{H}_0 = \sum_{i=1,2} h_0^{(i)}, \quad \text{with} \quad h_0^{(i)} = -\tfrac{1}{2}\boldsymbol{\nabla}_i^2 - \frac{Z}{\rho_i}. \tag{7.9}$$

Note that $h_0^{(i)}$ is the Schrödinger Hamiltonian of electron $i \in \{1,2\}$ in the Coulomb field of the bare nucleus, $\rho_i = r_i/a_0$ being its distance to the nucleus (in Bohr radii) and $\boldsymbol{\nabla}_i$ the gradient operator with respect to $\boldsymbol{\rho}_i$. We will treat $\mathcal{H}_0$ as the unperturbed Hamiltonian. The second term of Hamiltonian (7.8),

$$\mathcal{H}' = \frac{1}{\rho_{12}}, \tag{7.10}$$

acts as the perturbation by the electrostatic repulsion.

To first-order in perturbation theory, $\Delta\varepsilon_{1s} = \Delta\varepsilon_{1s}^{(1)}$, the energy shift is given by

$$\Delta\varepsilon_{1s} = \langle 1s, 1s|\mathcal{H}'|1s, 1s\rangle. \tag{7.11}$$

Let us postpone the actual evaluation of this expression until Section 7.4.3 and simply use the result:

$$\Delta\varepsilon_{1s} = \int_0^\infty U_{1s}(\rho)\tilde{R}_{1s}^2(\rho)\rho^2 d\rho, \tag{7.12}$$

where $\tilde{R}_{1s}(\rho) = Z^{3/2}2e^{-Z\rho}$ is the $1s$ radial wavefunction and

$$U_{1s}(\rho) = \frac{1}{\rho}\left[1 - (1 + Z\rho)e^{-2Z\rho}\right], \tag{7.13}$$

is the expectation value of the Coulomb repulsion energy of the atom with one electron fixed at position ρ. Note that the form (7.12) suggests to interpret $U_{1s}(\rho)$ semiclassically as some kind of effective potential field for *one* of the $1s$ electrons (the *spectator electron*) in the electrostatic field of the other $1s$ electron (the *screening electron*),

$$\Delta\varepsilon_{1s} = \langle 1s|U_{1s}(\rho)|1s\rangle. \tag{7.14}$$

The effective potential $U_{1s}(\rho)$ is called the *potential energy of screening* (short: *screening potential*), a notion from classical electrostatics used to account for the field associated with a charge-density distribution. In the present context the charge density arises from a semiclassical approximation in which the charge of the $1s$ electron, $-e$, is distributed in space proportional to the probability density of the wavefunction. In the upper panel of Fig. 7.2*a* the screening potential is plotted for the helium ground state. It is instructive to write the screening potential in the form

$$U_{1s}(\rho) = \sigma_{1s}(\rho)/\rho, \tag{7.15}$$

where $\sigma_{1s}(\rho)$ is the *screening charge* at distance ρ from the nucleus. This screening charge can be regarded as a generalization of the *screening constant* introduced in Section 4.6.2.1. As shown in Fig. 7.2*b* $\sigma_{1s}(\rho)$ grows from *zero* at $\rho = 0$ to *unity* for $\rho \gg 1$. Accordingly, far from the nucleus

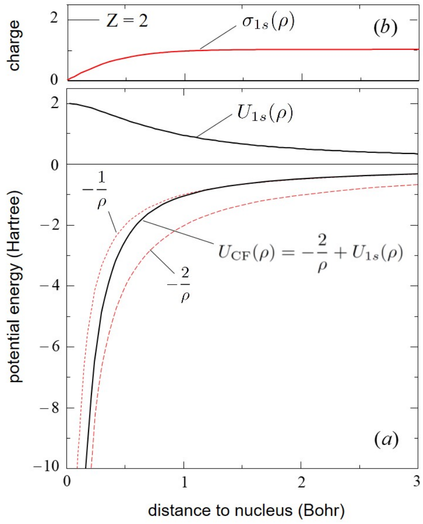

Figure 7.2: (a) Effective central field potential $U_{\rm CF}(\rho) = Z_{1s}(\rho)/\rho$ and screening potential $U_{1s}(\rho)$ for the helium atom ($Z = 2$) in its ground state. For comparison also the $-1/\rho$ hydrogenic Coulomb potential is shown (short dash) as well as the $-2/\rho$ potential of the unscreened helium nucleus (long dash), demonstrating that for an electron at distances $\rho \gg 1$ a full elementary charge of the nucleus is screened by "the other" electron; (b) Screening charge $\sigma_{1s}(\rho)$ corresponding to the screening potential $U_{1s}(\rho)$.

$U_{1s}(\rho)$ falls off like $1/\rho$. Apparently, for the spectator electron at large distance a full elementary charge of the nucleus is screened by the other electron, which is intuitively correct. Close to the nucleus the screening potential reaches the constant value Z,

$$U_{1s}(\rho) = Z - \tfrac{2}{3}Z^3\rho^2 + \cdots \quad \text{for } \rho \ll 1. \tag{7.16}$$

The constant Z represents the *mean electrostatic repulsion energy* (in atomic units) between the spectator electron close to the nucleus and the surrounding cloud of electronic charge. The precise value depends on the charge distribution but it being constant implies that the screening can be neglected close to the nucleus (where the nuclear scalar potential diverges as $-Z/\rho$). This is in accordance with the absence of screening charge, $\sigma_{1s}(0) = 0$, and certainly also intuitively correct.

Combining $U_{1s}(\rho)$ with the potential energy of the spectator electron in the Coulomb field of the nucleus we obtain the *effective central potential field* shown in the lower panel of Fig. 7.2a,

$$U_{\rm CF}(\rho) = -\frac{Z}{\rho} + U_{1s}(\rho) = -\frac{1}{\rho}\left[Z - \sigma_{1s}(\rho)\right] = -\frac{Z_{1s}(\rho)}{\rho}. \tag{7.17}$$

The function $Z_{1s}(\rho)$ is the *effective nuclear charge* for a $1s$ electron at distance r from the nucleus as introduced in Section 4.4.2,

$$Z_{1s}(\rho) = (Z - \sigma_{1s}) = \begin{cases} Z - Z\,\rho + \frac{2}{3}Z^3\rho^3 + \cdots & \text{for } \rho \ll 1 \\ 1 + \cdots & \text{for } \rho \gg 1. \end{cases} \tag{7.18}$$

Sometimes preference is given to a multiplicative screening correction to the Coulomb field,

$$U_{\rm CF}(\rho) = -\frac{Z}{\rho}\tilde{F}(\rho), \tag{7.19}$$

The correction factor,

$$\tilde{F}(\rho) \equiv Z(\rho)/Z, \tag{7.20}$$

is called the screening function for a given charge-density distribution $Z(\rho)$. A famous example is the Thomas-Fermi function - see Section 8.3.1.

So, screening by an s electron conserves the *central symmetry* (hence also the rotational structure derived in Chapter 1 for central potentials). The potential $U_{\mathrm{CF}}(\rho)$ is the first example of a class of electrostatic potentials which are *central* but do not have the familiar $1/\rho$ dependence of the Coulomb potential. Close to the nucleus the effective nuclear charge, $Z(\rho)$, approaches the bare nuclear charge, Z. Far from the nucleus, $Z(\rho)$ approaches *unity* because the nucleus can be screened by all electrons but not by the spectator electron itself. Although the concept of an effective potential is attractive from the computational point of view it should be remembered that it represents a semiclassical approximation in which *correlations* in the relative motion of the electrons are neglected. Such correlations have to be present in view of the strong Coulomb repulsion between two $1s$ electrons at short distance.[1] The concept of the central electrostatic potential is the stepping stone toward the description of many-electron atoms and we return to this concept in Chapter 8.

To conclude this section we evaluate the screening integral (7.12),

$$\Delta\varepsilon_{1s} = \int_0^\infty \left[1-(1+Z\rho)e^{-2Z\rho}\right]\left[Z^{3/2}2e^{-Z\rho}\right]^2 \rho d\rho = \tfrac{5}{8}Z. \tag{7.21}$$

Hence, the total energy of a helium-like atom is found to be

$$E_{1s^2}^{(1)} = E_{1s^2}^{(0)} + \Delta E_{1s} = hcR_\infty\left[-2Z^2 + \tfrac{5}{4}Z\right]. \tag{7.22}$$

Here we restored the dimension by multiplying with the Hartree, $E_H = 2hcR_\infty$. For the helium ground state ($Z=2$) this implies $E_{1s^2}^{(1)} = -(11/2)hcR_\infty = -74.8$ eV. The energy shift ΔE_{1s} of the ground state level is illustrated in the Term diagrams of Fig. 7.3. Adding the perturbation reduces the binding by 34.4 eV, which is the screening effect we are looking for. Comparing the energy obtained for the ground state of He with the energy of the ground state of the He$^+$ ion, $E_{1s} = -4hcR_\infty = -54.4$ eV, we see that to first-order in perturbation theory the ionization energy of the second electron is $-E_{1s}^{(0)} - \Delta E_{1s} = hcR_\infty\left[Z^2 - \tfrac{5}{4}Z\right] = 20.4$ eV, less than the measured value of 24.6 eV but much better than the 54.4 eV obtained in zero order (without screening). Apparently the screening correction of 34.4 eV overestimates the experimental value (29.8 eV) by 4.2 eV (14%), actually not bad for a first try but of course poor as compared to the results obtained for hydrogen.

7.1.2 Variational calculation

At this point we have established that first order perturbation theory is inadequate to provide a satisfactory description of even the simplest many-electron atom. We could proceed by calculating the second order terms but this turns out to make little sense because the convergence of the perturbation series is too slow. Apparently, the effective potential $U_{1s}(\rho)$ in combination with the $1s$ wavefunction of the unperturbed atom does not properly represent the actual charge distribution in the atom. This observation suggests to try a different approach and use Eq. (7.11) as an Ansatz to minimize the energy using the variational procedure of Appendix I.2.1. We vary the $1s$ wavefunction,

$$\tilde{R}_{1s}(\rho) = Z^{3/2}2e^{-Z\rho},$$

treating Z as the variational parameter. Interestingly, note that in this variational procedure both the $1s$ shape and the normalization remain conserved. To avoid confusion with the variational parameter (Z) the nuclear charge number is denoted by $\mathcal{Z}$. Using Eqs. (2.52) and (2.49) we obtain

$$E_{1s^2}^{(0)} = 2\langle 1s| - \frac{1}{2\rho}\frac{\partial^2}{\partial\rho^2}\rho + \frac{l(l+1)}{2\rho^2} - \frac{\mathcal{Z}}{\rho}|1s\rangle = 2\left(Z^2 - 2\mathcal{Z}Z\right)hcR_\infty. \tag{7.23}$$

---

[1] Note that we tacitly assume a *paired* spin state (Pauli principle satisfied).

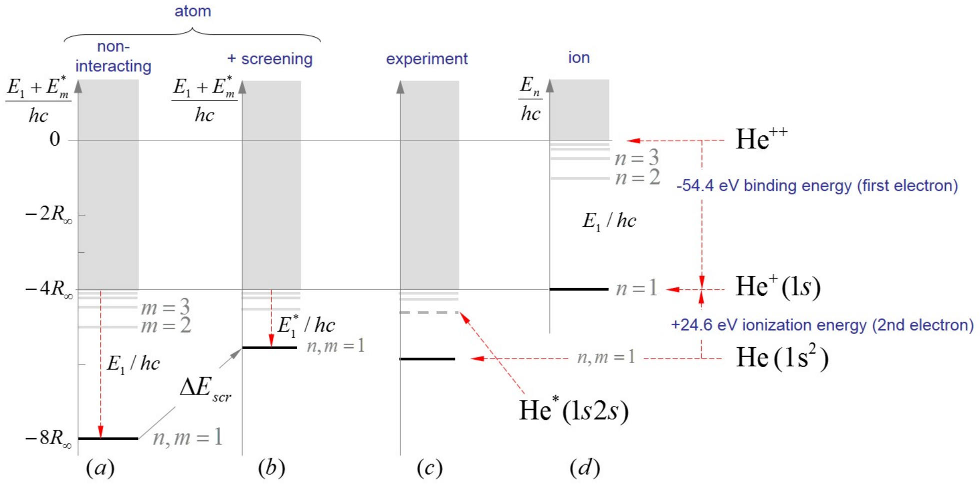

Figure 7.3: Energy level diagram for the ground state of *helium* showing the effect of electrostatic screening: (a) $1s^2$ configuration without the electrostatic interaction between the electrons; (b) $1s^2$ configuration with electrostatic screening calculated by first-order perturbation theory (E_m^* is the binding energy of the second electron); (c) diagram experimental values; (d) $1s$ configuration of the He$^+$ ion. Comparison with experiment for the helium ground state shows that even first-order perturbation theory gives a reasonable estimate for the electrostatic screening. Also the energy of *metastable triplet helium* (He*) is indicated.

Adding to this the screening energy as given by Eq. (7.21) we find for the total energy

$$E_{1s^2}^{(1)} = E_{1s^2}^{(0)} + \Delta E_{1s} = 2\left[Z^2 + (5/8 - 2\mathcal{Z})Z\right] hcR_\infty. \tag{7.24}$$

Taking the derivative with respect to Z we find that the energy $E_{1s^2}^{(1)}$ reaches its minimum value for $Z = Z_{\text{eff}} \equiv \mathcal{Z} - 5/16$. Substituting this result into Eq. (7.24) we obtain

$$E_{1s^2}^{(1)} = -2\,(\mathcal{Z} - 5/16)^2\, hcR_\infty. \tag{7.25}$$

For the helium ground state ($\mathcal{Z} = 2$) we find $E_{1s^2}^{(1)} = -2(27/16)^2 hcR_\infty = -77.4$ eV, which corresponds to a binding energy of 23.0 eV and $Z_{1s} = 27/16 = 1.69$. The corresponding wavefunction is shown as the dashed line in Fig. 7.1. As expected the $1s$ orbitals are inflated in comparison to the unscreened states. This variational result still deviates from the experimental value by 1.6 eV but is clearly better than the 4.2 eV discrepancy obtained by first-order perturbation theory. The screening correction is reduced to 31.4 eV, still overestimating the experimental value by 5.4%.

7.1.3 The hydrogen negative ion H$^-$

The substantial improvement in binding energy obtained with the variational method is encouraging, in particular since there is no reason why the $1s$ shape of the wavefunction would be the best. Hence, further improvement is to be expected with more sophisticated variational wavefunctions. We discuss this for the hydrogen negative ion, H^-, which is a negatively charged helium-like atom consisting of two electrons bound to a proton. In chemistry the H^- ion is sometimes called the *hydride ion*. Experimentally, H^- is found to be weakly bound with a binding energy

$$E_{1s^2}^{(\text{exp})} \approx -1.055\, hcR_\infty, \tag{7.26}$$

i.e., the second electron is bound by 0.75 eV to the neutral atom. As hydrogen is the most abundant atom in the universe the existence of a stable negative ion of hydrogen is of obvious astrophysical significance [25]. In theoretical physics the ion is not of less significance because its existence cannot be demonstrated without taking into account the electronic correlations.

Neglecting the correlations, we regain (by first-order perturbation theory) the result (7.22) for the binding energy of the ground state of helium-like atoms,

$$E_{1s^2}^{(1)} = hcR_\infty \left[-2Z^2 + \tfrac{5}{4}Z\right]. \tag{7.27}$$

For the H^- ion ($Z = 1$) this implies $E_{1s^2}^{(1)} = -\frac{3}{4}\,hcR_\infty$, which is larger than $E_{1s} = -hcR_\infty$ of the neutral hydrogen atom. Hence, according to first-order perturbation theory the proton cannot bind two electrons. To have binding of two electrons one requires $E_{1s^2}^{(1)} < E_{1s} = -hcR_\infty$ (which is the case for $Z > 1.08$). With the variational principle we can do better than first-order perturbation theory; with Eq. (7.25) we find for $\mathcal{Z} = 1$

$$E_{1s^2}^{(1)} = -2\,(11/16)^2\,hcR_\infty = -0.945\,31\,hcR_\infty. \tag{7.28}$$

Although this variational result is better it is still not good enough to bind the ion.

To achieve binding the calculation has to account for the presence of correlations in the electron motion because these tend to increase the average distance between the electrons. This obviously lowers the electrostatic repulsion and, therefore increases the binding energy. The key idea of accounting for such correlations (even without sacrificing the central symmetry) was published in a famous paper by Chandrasekhar [25]. The average distance between the electrons can be increased by writing the two-electron wavefunction as the product state of two s electrons with *different* Bohr radius,

$$\psi(\rho_1,\rho_2) = e^{-a\rho_1 - b\rho_2} + e^{-b\rho_1 - a\rho_2}. \tag{7.29}$$

Using the variational principle (see Appendix I.2.1) the lowest energy for the ground state is obtained for $a = 1.03925$ and $b = 0.28309$ and the binding energy is

$$E_{1s^2}^{(\mathrm{var})} \approx -1.026\,6\,hcR_\infty. \tag{7.30}$$

The actual calculation represents a substantial two-dimensional variational problem, which is not reproduced here. The result is quite intuitive. One electron remains almost hydrogenic with its Bohr radius only slightly compressed. The other electron is largely inflated (the Bohr radius increases by a factor 3.5). This is exactly what we expect. As the nuclear charge is strongly shielded by the first electron, the second electron has its largest probability far from the nucleus and has to be weakly bound. It may speak for itself that by choosing a still more sophisticated variational wavefunction the ground state energy can be further lowered. In this way high precision can be obtained for helium-like atoms [35].

7.1.4 Effective potential and self-consistent mean field

The success of the variational method calls for a systematic approach to optimize the shape of the ground state wavefunction in the presence of screening. What is the best shape? To answer this question, let us suppose that the ground state is a product state of the form $|u_1,u_2) = |u_1\rangle_1 \otimes |u_2\rangle_2$, with electron-1 in s-orbital u_1 and electron-2 in s-orbital u_2; i.e., for the time being the electrons are treated as distinguishable. In this notation the energy of the state $|u_1,u_2)$ is given by the expectation value of the Hamiltonian (7.8),

$$\varepsilon = (u_1,u_2|\mathcal{H}|u_1,u_2) = \sum_{i=1}^{2}\langle u_i|h_0|u_i\rangle + (u_1,u_2|\frac{1}{\rho_{12}}|u_1,u_2). \tag{7.31}$$

We dropped the particle index on the Schrödinger operators, $h_0^{(i)} \to h_0$, with $i \in \{1,2\}$, because (for identical particles) there can be no confusion about the integral to be evaluated. Since the orbitals

u_1 and u_2 are still to be determined the expectation value ε can be regarded as a functional of u_1 and u_2. To optimize the orbitals u_i we minimize the energy functional (7.31)

$$H_i(u_1,u_2) = \langle u_i|h_0|u_i\rangle + (u_1,u_2|\frac{1}{\rho_{12}}|u_1,u_2) \tag{7.32}$$

by variation of $\langle u_i|$ using the variational procedure of Appendix I.1.3 starting from hydrogenic s orbitals. Introducing the effective potential of screening of electron i by electron j, with $i \neq j \in \{1,2\}$,

$$U_{\mathrm{scr}}(\rho_i) = \langle u_j|1/\rho_{ij}|u_j\rangle \tag{7.33}$$

the functional $H_i(u_1,u_2)$ can be written in the form

$$H_i(u_1,u_2) = \langle u_i|h(\rho_i)|u_i\rangle, \tag{7.34}$$

where

$$h(\rho_i) = h_0^{(i)} + U_{\mathrm{scr}}(\rho_i). \tag{7.35}$$

For s orbitals $U_{\mathrm{scr}}(\rho_i)$ is a central potential as will be shown in Section 7.4.3. To conserve the normalization of the states, H_i has to be minimized under the constraint $\langle u_i|u_i\rangle = 1$, with $i \in \{1,2\}$. Hence, the lagrangian for the variation of $\langle u_i|$ is

$$\mathcal{L}_i(u_1,u_2,\lambda_i) = \langle u_i|h(\rho_i)|u_i\rangle + \lambda_i\left[\langle u_i|u_i\rangle - 1\right], \tag{7.36}$$

where λ_i is the Lagrange multiplier for the constraint $\langle u_i|u_i\rangle = 1$, with $i \in \{1,2\}$.[1] As discussed in Appendix I.1.3, after minimization of the lagrangian (8.60) under variation of $\langle u_i|$ the state $|u_i\rangle$ is found as the solution with eigenvalue $\varepsilon_i = -\lambda_i$ of an effective single-electron Schrödinger equation,

$$h\,u_i(\boldsymbol{\rho}) = \varepsilon_i u_i(\boldsymbol{\rho}). \tag{7.37}$$

This expression corresponds to a set of 2 integro-differential equations, one for each electron and coupled by the screening integrals $U_{\mathrm{scr}}(\rho_1)$ and $U_{\mathrm{scr}}(\rho_2)$.

Note that the ground state energy is not simply the sum of the optimized single electron energies $\varepsilon \neq \varepsilon_1 + \varepsilon_2$ because the functionals H_1 and H_2 both contain the same repulsion term. Comparing with Eq. (7.31) we find that the energy of the ground state follows from

$$\varepsilon = \varepsilon_1 + \varepsilon_2 - (u_1,u_2|1/\rho_{12}|u_1,u_2). \tag{7.38}$$

To solve Eqs. (7.37) we start with hydrogenic $1s$ wavefunctions, $u_i(\boldsymbol{\rho}) = \langle\boldsymbol{\rho}|u_i\rangle = R_{1s}^{(i)}(\rho)Y_0^0(\hat{\mathbf{r}})$, and calculate the screening potentials. With these potentials we can solve Eqs. (7.37) numerically and obtain improved expressions for the wavefunctions. This, of course, gives rise to an inconsistency because the new wavefunctions imply different screening, modifying the effective single-electron Schrödinger equation to be solved. Thus the procedure has to be repeated until a *self-consistent solution* is reached for the *mean field.* The principal drawback of this approach is that by constructing the semiclassical effective field, correlations in the relative motion of the electrons are neglected. This approximation is best suited to describe large atoms because the concept of a local charge density becomes exact in the classical limit. Mean field methods based on variation of the wavefunction are known as Hartree (see Chapter 8) or Hartree-Fock (see Chapter 10) theories.

Actually, the observation that the Coulomb interaction is the dominant interaction in the atom suggests a semiclassical approach in which the wavefunction does not appear at all but a quantum statistical model is used to calculate the distribution of the electronic charge (or, equivalently, the electrostatic potential). Statistical methods for these semiclassical quantities are called density functional or potential functional methods. They work best for atoms with a large number of electrons because in this case the concept of a local charge density is best justified. We return to semiclassical approaches in Chapter 8. Whatever the quantity being varied (wavefunction, density distribution or effective potential), the general idea is that the calculation of the atomic energy levels can be strongly improved by the proper optimization procedure.

---

[1] Note that for this lagrangian the normalization of the orbitals is enforced but their orthogonality is *not.*

7.2 The helium ground state in a magnetic field

A lot can be learned by analyzing the behavior of the ^{4}He atom in an externally applied magnetic field $\mathbf{B}$. Remarkably, this is because little happens! A small diamagnetic shift may be observed but no Zeeman splitting, in spite of the presence of two electrons each carrying a Bohr magneton. *A priori* this is surprising. As we are dealing with s orbitals the orbital angular momentum of the atom is zero. Because the nuclear spin of ^{4}He is also zero all angular momentum has to come from the electronic spin. The conserved quantity is the total angular momentum $\mathbf{S} = \mathbf{s}_1 + \mathbf{s}_2$. Because $s_1 = s_2 = 1/2$ we have two possibilities for coupling of these spins, *parallel* ($S = 1$) or *anti-parallel* ($S = 0$). In a sufficiently weak probe field we expect Zeeman coupling of the total spin to the field as described by a Hamiltonian of the spin-Zeeman type,

$$\mathcal{H}_Z = g_S \mu_B B \left(S_z/\hbar\right), \tag{7.39}$$

where g_S is the g factor for the total spin $\mathbf{S}$. The Zeeman shifts are obtained with first-order perturbation theory, just as in the case of the low-field limit of the fine- or hyperfine structure,

$$E_z = g_S \mu_B M_S B. \tag{7.40}$$

Hence for $S = 1$ we expect the ground state to split into a triplet. For $S = 0$ we expect a singlet, no splitting and no Zeeman shift. As mentioned above *only the singlet is observed.* Apparently the triplet option, in which both electrons are in the same (orbital + spin) state, has to be *excluded.* Also in strong magnetic fields the degeneracy is not lifted, which points to $\mathbf{s}_1 \cdot \mathbf{s}_2$ coupling because for this type of coupling $M_S = m_{s_1} + m_{s_2}$ is conserved in accordance with the commutation relation $[S_z, \mathbf{s}_1 \cdot \mathbf{s}_2] = 0$. Pauli generalized similar observations into his *exclusion principle.*

7.3 Exchange degeneracy and Pauli principle

If two electrons are in *different* orbitals, $|u\rangle = |nlm_l\rangle$ and $|v\rangle = |n'l'm_{l'}\rangle$, the same pair energy is obtained irrespective of which of the two electrons is in state $|u\rangle$ and which in state $|v\rangle$,

$$(u, v|\mathcal{H}_0|u, v) = E_{n_u} + E_{n_v} \tag{7.41a}$$

$$(v, u|\mathcal{H}_0|v, u) = E_{n_v} + E_{n_u}. \tag{7.41b}$$

This phenomenon is called *exchange degeneracy.* It implies that any linear combination of the type

$$\psi_{uv}\left(\mathbf{r}_1, \mathbf{r}_2\right) = \frac{1}{\sqrt{|c_1|^2 + |c_2|^2}} \left\{c_1 \varphi_u\left(\mathbf{r}_1\right) \varphi_v\left(\mathbf{r}_2\right) + c_2 \varphi_v\left(\mathbf{r}_1\right) \varphi_u\left(\mathbf{r}_2\right)\right\} \tag{7.42}$$

represents a properly normalized energy eigenstate of the pair; hence, for any choice of c_1 and c_2 we can construct an orthogonal pair state with the same energy.

Note that if the electrons would have a slightly different mass their hydrogenic energies would be different, $E_{n_u 1} \neq E_{n_u 2}$, and the exchange degeneracy would be absent, $E_{n_u 1} + E_{n_v 2} \neq E_{n_v 1} + E_{n_u 2}$. Exchange degeneracy arises if the particles to be exchanged cannot be distinguished. As a consequence the Hamiltonian (7.1) is invariant under interchange of the electrons.

Let us analyze how the exchange degeneracy (7.41a) is *lifted* by the Coulomb term (7.10) using perturbation theory for a doubly degenerate level (see Appendix H.3). Like in Section 7.1 we split the Hamiltonian (7.8) in the form

$$\mathcal{H} = \mathcal{H}_0 + \mathcal{H}', \tag{7.43}$$

where $\mathcal{H}_0$ is again as *unperturbed* Hamiltonian and the electrostatic repulsion, $\mathcal{H}' = \rho_{12}^{-1}$, is the perturbation. For each pair of hydrogenic states $|u\rangle$ and $|v\rangle$ an exchange degenerate pair can be defined, $|a) = |u, v)$ and $|b) = |v, u)$. It is straightforward to show that $\mathcal{H}'_{aa} = (a|\mathcal{H}'|a) = (b|\mathcal{H}'|b) =$

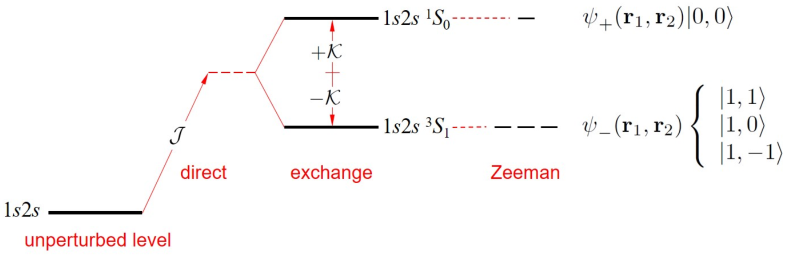

Figure 7.4: Exchange tends to "align" the electron spins in atoms. The energy level diagram shows the direct and exchange shifts for helium atoms with two nonequivalent electrons. Because $\mathcal{K}$ is always positive the antisymmetric orbital has always the lowest energy. Experiments show that the lowest pair state is always a spin triplet and the highest pair state a spin singlet.

$\mathcal{H}'_{bb} \equiv \mathcal{J}$. Furthermore we have $\mathcal{H}'_{ab} = (a|\mathcal{H}'|b) = (b|\mathcal{H}'|a) = \mathcal{H}'_{ba} \equiv \mathcal{K}$, as follows from the hermiticity of $\mathcal{H}'$. The overlap integrals S_{ab} introduced in Appendix H.3 are zero because the hydrogenic eigenstates are orthogonal, $S_{ab} = (a|b) = (b|a) = S_{ba} = 0$. Solving the secular equation (H.70) we find the result of first order perturbation theory of a two-fold degenerate level (*symmetric case* of *strong coupling*),

$$E_{\pm}^{(1)} = E_{uv}^{(0)} + \Delta E_{\pm}, \tag{7.44}$$

where $\Delta E_{\pm}$ can be written in the form of Eqs. (G.38) and (G.55),

$$\Delta E_{\pm} = \mathcal{J} \pm \mathcal{K}. \tag{7.45}$$

The $\Delta E_{\pm}$ represent the energy level shifts caused by the electrostatic repulsion. The integrals

$$\mathcal{J}(u, v) = (u, v|\rho_{12}^{-1}|u, v) \tag{7.46a}$$

$$\mathcal{K}(u, v) = (u, v|\rho_{12}^{-1}|v, u) \tag{7.46b}$$

are called the *direct* ($\mathcal{J}$) and the *exchange* ($\mathcal{K}$) contribution to the energy shift. Note the properties

$$\mathcal{J}(u, v) = \mathcal{J}(v, u) \quad \text{and} \quad \mathcal{K}(u, v) = \mathcal{K}(v, u). \tag{7.47}$$

The eigenstates corresponding to the shifts (7.45) are

$$\psi_{u,v}^{\pm}(\mathbf{r}_1, \mathbf{r}_2) = \sqrt{\tfrac{1}{2}}\left\{\varphi_u(\mathbf{r}_1)\varphi_v(\mathbf{r}_2) \pm \varphi_v(\mathbf{r}_1)\varphi_u(\mathbf{r}_2)\right\}, \tag{7.48}$$

which correspond to the symmetric (+) and antisymmetric (−) linear combinations of the pair states $|u, v)$ and $|v, u)$. The situation is sketched in Fig. 7.4. The matrix elements $\mathcal{J}$ and $\mathcal{K}$ are called the *Coulomb integrals of the electrostatic repulsion.*

Two important features should be pointed out for the antisymmetric pair state $|\psi_-\rangle$. First we note that $|\psi_-\rangle$ has the lowest energy. This is intuitively clear because the electrostatic repulsion is largest when the electrons come close to each other and precisely this probability is excluded by the antisymmetric form. The probability of finding two electrons at the same position is identically zero. This follows directly by substituting $\mathbf{r}_1 = \mathbf{r}_2 = \mathbf{r}$ into the antisymmetric form of the pair wavefunctions (7.48),

$$\psi_{u,v}^{-}(\mathbf{r}, \mathbf{r}) = \sqrt{\tfrac{1}{2}}\left\{\varphi_u(\mathbf{r})\varphi_v(\mathbf{r}) - \varphi_v(\mathbf{r})\varphi_u(\mathbf{r})\right\} \equiv 0. \tag{7.49}$$

Hence the electrostatic repulsion is smallest in the antisymmetric case. This increases the binding energy of the electron pair and lowers the total energy of atoms in antisymmetric states with respect to atoms in the corresponding symmetric states.

A second point to note holds for two electrons in the same orbital, $|u\rangle = |v\rangle$, for instance the $1s^2$ configuration of the helium ground state discussed in Section 7.1. In this case the antisymmetric wavefunction is also identically zero, whatever the positions of the two electrons,

$$\psi^{-}_{u,u}(\mathbf{r}_1, \mathbf{r}_2) = \sqrt{\tfrac{1}{2}}\left\{\varphi_u(\mathbf{r}_1)\varphi_u(\mathbf{r}_2) - \varphi_u(\mathbf{r}_1)\varphi_u(\mathbf{r}_2)\right\} \equiv 0. \tag{7.50}$$

For two electrons in the same orbital only the symmetric state is an option,

$$\psi_{u,u}(\mathbf{r}_1, \mathbf{r}_2) = \varphi_u(\mathbf{r}_1)\varphi_u(\mathbf{r}_2). \tag{7.51}$$

Note that this wavefunction is both symmetrized and normalized to start with. Actually, the explicit symmetrization (7.48) yields the *wrong* normalization as $\psi^{\pm}$ were derived for the case $u \neq v$; i.e., for the presence of exchange degeneracy. For electrons in the same orbital exchange degeneracy is absent and the energy shift caused by electrostatic repulsion between the electrons is given by the direct shift only

$$\Delta E_{\mathrm{scr}} = \mathcal{J} = (u, u|\mathcal{H}'|u, u). \tag{7.52}$$

Thus we arrived at two important conclusions: (*a*) two electrons in an antisymmetric orbital pair state have *zero probability* to be found at the same position; (*b*) two electrons in the same orbital state are represented by the simple product state (7.51) and not by Eq. (7.42). Pauli noticed that in *two-electron atoms* (Pauli studied the alkaline-earth elements) the antisymmetric orbital is always a spin triplet ($S = 1$) whereas the symmetric orbital always a spin singlet ($S = 0$).[1] This is illustrated in Fig. 7.4. As the spin triplet is symmetric and the spin singlet antisymmetric under exchange of the two electrons (see Problem 7.2), this shows that the overall electron pair state (orbital + spin) must be antisymmetric under exchange of the two electrons; i.e., electrons are fermionic particles. Pauli summarized these and other observations in his famous exclusion principle: no two electrons can occupy the same (orbital + spin) state [82].

The symmetric spin state is energetically favored over the antisymmetric spin state. Phenomenologically, this emerges as the result of some *effective magnetic interaction* which tends to align the spins in atoms. This effective interaction is called the *exchange interaction.* It is much stronger than a truly magnetic interaction because its origin is *electrostatic* and not magnetic at all.

Problem 7.2. Show that the spin triplet is symmetric and the spin singlet antisymmetric under exchange of two $s = \frac{1}{2}$ particles.

Solution. The symmetry of the total spin state under exchange of the two $s = \frac{1}{2}$ particles is found by Clebsch-Gordan decomposition,

$$|S, M\rangle = \sum_{m_1, m_2} |s, m_1; s, m_2\rangle\langle s, m_1; s, m_2|S, M\rangle. \tag{7.53}$$

Using Table J.2.1 for the Clebsch-Gordan coefficients (in the Condon and Shortley phase convention) we obtain

$$\left.\begin{array}{ll} |1,+1\rangle & = |\uparrow\uparrow\rangle \\ |1,0\rangle & = \sqrt{1/2}\,[|\uparrow\downarrow\rangle + |\downarrow\uparrow\rangle] \\ |1,-1\rangle & = |\downarrow\downarrow\rangle \end{array}\right\} \quad (S=1)$$
$$|0,0\rangle = \sqrt{1/2}\,[|\uparrow\downarrow\rangle - |\downarrow\uparrow\rangle] \qquad (S=0), \tag{7.54}$$

which demonstrates the requested symmetry. □

---

[1] The other combination (symmetric orbital state with spin singlet and antisymmetric orbital state with spin triplet) is not observed although this would be expected given the angular momentum addition rules.

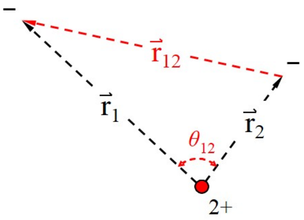

Figure 7.5: Doubly-charged nucleus with electrons at positions indicated by the vectors $\mathbf{r}_1$ and $\mathbf{r}_2$ (enclosing the angles θ_{12}) as well as the vector for the relative position $\mathbf{r}_{12}$.

7.4 Expressions for the Coulomb integrals

Rather than evaluating a special case we derive in this section general expressions for the diagonal and off-diagonal matrix elements of the electrostatic repulsion between atomic orbitals. In Hartree atomic units the electrostatic repulsion between two electrons is given by

$$\mathcal{H}'(\rho_{12}) = \frac{1}{\rho_{12}} = \frac{1}{(\rho_1^2 + \rho_2^2 - 2\rho_1\rho_2\cos\theta_{12})^{1/2}}. \tag{7.55}$$

Here the cosine rule is used to express the relative distance between the electrons, $\rho_{12} = |\boldsymbol{\rho}_1 - \boldsymbol{\rho}_2|$, in terms of the absolute positions $\boldsymbol{\rho}_1$ and $\boldsymbol{\rho}_2$ relative to the nucleus and the angle θ_{12} enclosed by the directions $\hat{\mathbf{r}}_1$ and $\hat{\mathbf{r}}_2$ (see Fig. 7.5). This is important for the calculation of matrix elements because the electronic wavefunctions are defined in terms of the variables $\boldsymbol{\rho}_1$ and $\boldsymbol{\rho}_2$. Recalling the radial averages (2.49) we expand Eq. (7.55) in powers of the ratio $(\rho_</\rho_>)$, where $\rho_< = \min\{\rho_1, \rho_2\}$ is the lesser and $\rho_> = \max\{\rho_1, \rho_2\}$ the greater of ρ_1 and ρ_2,

$$\mathcal{H}'(\rho_{12}) = \frac{1}{\rho_>}\sum_{k=0}^{\infty}\left(\frac{\rho_<}{\rho_>}\right)^k P_k(\cos\theta_{12}). \tag{7.56}$$

The functions $P_k(u)$ are Legendre polynomials of order k (see Appendix L.9). What remains to be done is to express the relative angle θ_{12} into absolute position angles $\hat{\mathbf{r}}_1$ and $\hat{\mathbf{r}}_2$ of the individual electrons. This is done with the aid of the spherical harmonic *addition theorem* (L.56),

$$P_k(\cos\theta_{12}) = \frac{4\pi}{2k+1}\sum_{m=-k}^{k} Y_k^{m*}(\hat{\mathbf{r}}_1)Y_k^m(\hat{\mathbf{r}}_2). \tag{7.57}$$

Substituting this expression into the expansion (7.56) the perturbation takes the form of a *multipole expansion*, which is suited for evaluation with hydrogenic wavefunctions,

$$\mathcal{H}'(\rho_{12}) = \frac{1}{\rho_>}\sum_{k=0}^{\infty}\left(\frac{\rho_<}{\rho_>}\right)^k \frac{4\pi}{2k+1}\sum_{m=-k}^{k} Y_k^{m*}(\hat{\mathbf{r}}_1)Y_k^m(\hat{\mathbf{r}}_2). \tag{7.58}$$

This form is optimal for the evaluation of the Coulomb integrals (7.46). Using the multipole expansion the integrals $\mathcal{J}$ and $\mathcal{K}$ can be expressed in the form

$$\mathcal{J} = (nlm_l; n'l'm_{l'}|\frac{1}{\rho_{12}}|nlm_l; n'l'm_{l'}) = \sum_{k=0}^{\infty} a^k(lm_l; l'm_{l'})F^k(nl; n'l') \tag{7.59a}$$

$$\mathcal{K} = (nlm_l; n'l'm_{l'}|\frac{1}{\rho_{12}}|n'l'm_{l'}; nlm_l) = \sum_{k=0}^{\infty} b^k(lm_l; l'm_{l'})G^k(nl; n'l'), \tag{7.59b}$$

The coefficients $a^k(lm_l; l'm_{l'})$ and $b^k(lm_l; l'm_{l'})$ represent the angular parts and $F^k(nl; n'l')$ and $G^k(nl; n'l')$ the radial parts of the *direct* ($\mathcal{J}$) and *exchange* ($\mathcal{K}$) contribution to the energy shift.

7.4.1 Angular integrals

The angular integrals can be expressed in $3j$ symbols (see Problem 7.3),

$$\begin{aligned}a^k(lm_l;l'm_{l'}) &= \frac{4\pi}{2k+1}\sum_{m=-k}^{k}\langle lm_l|Y_k^{m*}(\hat{\mathbf{r}}_1)|lm_l\rangle\langle l'm_{l'}|Y_k^m(\hat{\mathbf{r}}_2)|l'm_{l'}\rangle \\ &= (-)^{m_l+m_{l'}}(2l+1)(2l'+1)\begin{pmatrix} l\,k\,l \\ 0\,0\,0\end{pmatrix}\begin{pmatrix} l & k & l \\ -m_l & 0 & m_l\end{pmatrix}\begin{pmatrix} l'\,k\,l' \\ 0\,0\,0\end{pmatrix}\begin{pmatrix} l' & k & l' \\ -m_{l'} & 0 & m_{l'}\end{pmatrix} \qquad (7.60a)\end{aligned}$$

$$\begin{aligned}b^k(lm_l;l'm_{l'}) &= \frac{4\pi}{2k+1}\sum_{m=-k}^{k}\langle l'm_{l'}|Y_k^{m*}(\hat{\mathbf{r}}_1)|lm_l\rangle\langle lm_l|Y_k^m(\hat{\mathbf{r}}_2)|l'm_{l'}\rangle \\ &= (2l+1)(2l'+1)\begin{pmatrix} l\,k\,l' \\ 0\,0\,0\end{pmatrix}^2\begin{pmatrix} l & k & l' \\ -m_l & (m_l-m_{l'}) & m_{l'}\end{pmatrix}^2 \geq 0 \qquad (7.60b)\end{aligned}$$

where, in view of the properties of the $3j$ symbols,

$$a^k(lm_l;l'm_{l'}) = 0 \ \text{ unless } k = \text{even and } 0 \leq k \leq 2l_< \qquad (7.61)$$

$$b^k(lm_l;l'm_{l'}) = 0 \ \text{ unless } k+l+l' = \text{even and } |l-l'| \leq k \leq l+l', \qquad (7.62)$$

with $l_< = \min\{l,l'\}$ (the lesser of l and l'). The a^k coefficients can be positive, negative or zero. The b^k coefficients are positive or zero. Note that a^k and b^k coincide for electrons in the same state of angular momentum: $a^k(lm_l;lm_l) = b^k(lm_l;lm_l)$. Note further the symmetry under state reversal: $a^k(lm_l;l'm_{l'}) = a^k(l'm_{l'};lm_l)$ and $b^k(lm_l;l'm_{l'}) = b^k(l'm_{l'};lm_l)$. The a^k and b^k coefficients are readily calculated with a symbolic manipulation program like *Mathematica*. For the configurations s^2, sp, p^2, sd, pd, d^2 and f^2 the results are given in Table 7.1. The special cases $a^k(00;lm_l)$ and $b^k(00;lm_l)$ are discussed in Problems 7.10 and 7.11.

Problem 7.3. Derive equation 7.60a:

$$a^k(lm_l;l'm_{l'}) = (-)^{m_l+m_{l'}}(2l+1)(2l'+1)\begin{pmatrix} l\,k\,l \\ 0\,0\,0\end{pmatrix}\begin{pmatrix} l & k & l \\ -m_l & 0 & m_l\end{pmatrix}\begin{pmatrix} l'\,k\,l' \\ 0\,0\,0\end{pmatrix}\begin{pmatrix} l' & k & l' \\ -m_{l'} & 0 & m_{l'}\end{pmatrix}.$$

Solution. Using Eq. (L.53) and Eq. (L.59) for the integral over three spherical harmonics we obtain

$$\langle lm_l|Y_k^{m*}(\hat{\mathbf{r}}_1)|lm_l\rangle = (-1)^{m_l+m}(2l+1)\sqrt{\frac{(2k+1)}{4\pi}}\begin{pmatrix} l\,k\,l \\ 0\,0\,0\end{pmatrix}\begin{pmatrix} l & k & l \\ -m_l & -m & m_l\end{pmatrix}$$

$$\langle l'm_{l'}|Y_k^{m}(\hat{\mathbf{r}}_2)|l'm_{l'}\rangle = (-1)^{m_{l'}}(2l'+1)\sqrt{\frac{(2k+1)}{4\pi}}\begin{pmatrix} l'\,k\,l' \\ 0\,0\,0\end{pmatrix}\begin{pmatrix} l' & k & l' \\ -m_{l'} & m & m_{l'}\end{pmatrix}.$$

Multiplying these two expressions we find

$$\begin{aligned}&\frac{4\pi}{2k+1}\langle lm_l|Y_k^{m*}(\hat{\mathbf{r}}_1)|lm_l\rangle\langle l'm_{l'}|Y_k^m(\hat{\mathbf{r}}_2)|l'm_{l'}\rangle = \\ &\qquad = (-1)^{m_l+m_{l'}+m}(2l+1)(2l'+1)\begin{pmatrix} l\,k\,l \\ 0\,0\,0\end{pmatrix}\begin{pmatrix} l & k & l \\ -m_l & -m & m_l\end{pmatrix}\begin{pmatrix} l'\,k\,l' \\ 0\,0\,0\end{pmatrix}\begin{pmatrix} l' & k & l' \\ -m_{l'} & m & m_{l'}\end{pmatrix}.\end{aligned}$$

which is only nonzero for $0 \leq k \leq 2l_<$ and $m = 0$ because $\begin{pmatrix} j_1 & j_2 & j_3 \\ m_1 & m_2 & m_3\end{pmatrix} = 0$ unless $|j_1 - j_3| \leq j_2 \leq j_1 + j_3$ and $m_1 + m_2 + m_3 = 0$ (see Appendix J). □

Table 7.1: List of a^k and b^k coefficients for the ss, sp, pp, sd, pd, dd and ff configurations. For reasons of transparency the common denominators of the elements of the table are only printed at the top of the columns (of more than 3 rows); $\{m_l, m_{l'}\} = \{\pm a, \mp b\}$ stands for $\{m_l, m_{l'}\} = \{\{+a, -b\}$ *or* $\{-a, +b\}\}$.

Problem 7.4. Show that

$$a^0(lm_l;l'm_{l'}) = 1.$$

Solution. Using Eq. (J.16) we have

$$(-)^{m_l}(2l+1)\begin{pmatrix} l & 0 & l \\ 0 & 0 & 0 \end{pmatrix}\begin{pmatrix} l & 0 & l \\ -m_l & 0 & m_l \end{pmatrix} = 1.$$

Using this relation twice in Eq. (7.60a) we obtain $a^0(lm_l;l'm_{l'}) = 1$. □

Problem 7.5. Show that

$$\sum_{m=-l}^{l} a^k(lm;l'm') = 0 \text{ for } k \neq 0.$$

Solution. This result follows immediately by applying the shell-summation formula (J.20) to Eq. (J.16)

$$\begin{pmatrix} l & k & l \\ 0 & 0 & 0 \end{pmatrix}\sum_{m=-l}^{l}(-)^m\begin{pmatrix} l & k & l \\ -m & 0 & m \end{pmatrix} = 0.$$ □

Problem 7.6. Show that

$$\sum_{m=-l}^{l} b^k(lm;l'm') = (2l+1)\begin{pmatrix} l & k & l' \\ 0 & 0 & 0 \end{pmatrix}^2.$$

7.4.2 Radial integrals

The direct $\left(F^k\right)$ and exchange $\left(G^k\right)$ radial integrals are given by

$$F^k(nl;n'l') = \int_0^\infty \left\{ \frac{1}{\rho_1^{k+1}} \int_0^{\rho_1} \rho_2^k \left[\tilde{R}_{nl}(\rho_2)\right]^2 \rho_2^2 d\rho_2 + \right. \\ \left. + \rho_1^k \int_{\rho_1}^\infty \frac{1}{\rho_2^{k+1}} [\tilde{R}_{nl}(\rho_2)]^2 \rho_2^2 d\rho_2 \right\} \left[\tilde{R}_{n'l'}(\rho_1)\right]^2 \rho_1^2 d\rho_1 \tag{7.63a}$$

$$G^k(nl;n'l') = \int_0^\infty \left\{ \frac{1}{\rho_1^{k+1}} \int_0^{\rho_1} \rho_2^k \tilde{R}_{nl}(\rho_2)\tilde{R}_{n'l'}(\rho_2)\rho_2^2 d\rho_2 + \right. \\ \left. + \rho_1^k \int_{\rho_1}^\infty \frac{1}{\rho_2^{k+1}} \tilde{R}_{nl}(\rho_2)\tilde{R}_{n'l'}(\rho_2)\rho_2^2 d\rho_2 \right\} \tilde{R}_{nl}(\rho_1)\tilde{R}_{n'l'}(\rho_1)\rho_1^2 d\rho_1. \tag{7.63b}$$

Note that the radial integrals coincide for equivalent electrons, $F^k(nl;nl) = G^k(nl;nl)$. Furthermore, it is important to note that (like the a^k and b^k coefficients) the radial integrals are symmetric under state reversal, $F^k(nl;n'l') = F^k(n'l';nl)$ and $G^k(nl;n'l') = G^k(n'l';nl)$. The integrals can be reformulated in a more convenient and insightful form by introducing two *screening potentials*,

$$U_F^k(\rho) = \frac{1}{\rho^{k+1}} \int_0^\rho \varrho^k \left[\tilde{R}_{nl}(\varrho)\right]^2 \varrho^2 d\varrho + \rho^k \int_\rho^\infty \frac{1}{\varrho^{k+1}} \left[\tilde{R}_{nl}(\varrho)\right]^2 \varrho^2 d\varrho \tag{7.64a}$$

$$U_G^k(\rho) = \frac{1}{\rho^{k+1}} \int_0^\rho \varrho^k \tilde{R}_{nl}(\varrho)\tilde{R}_{n'l'}(\varrho)\, \varrho^2 d\varrho + \rho^k \int_\rho^\infty \frac{1}{\varrho^{k+1}} \tilde{R}_{nl}(\varrho)\tilde{R}_{n'l'}(\varrho)\, \varrho^2 d\varrho, \tag{7.64b}$$

where $U_F^k(\rho)$ is called the potential for *direct screening* and $U_G^k(\rho)$ the potential for *exchange screening* (note the change of notation: $\rho_1 \to \rho$; $\rho_2 \to \varrho$). With the aid of these potentials the radial integrals take the convenient form

$$F^k(nl;n'l') = \int_0^\infty U_F^k(\rho) \left[\tilde{R}_{n'l'}(\rho)\right]^2 \rho^2 d\rho, \tag{7.65a}$$

$$G^k(nl;n'l') = \int_0^\infty U_G^k(\rho)\tilde{R}_{nl}(\rho)\tilde{R}_{n'l'}(\rho)\rho^2 d\rho. \tag{7.65b}$$

For hydrogenic wavefunctions these integrals are conveniently calculated with a symbolic manipulation program like *Mathematica*.

Table 7.2: Coulomb integrals for orbitals corresponding to a zero-order Laguerre polynomial.

$F^k(nl^2)/Z$	$k=0$	$k=2$	$k=4$	$k=6$
$1s^2$	$\frac{5}{8}$			
$2p^2$	$\frac{93}{512}$	$\frac{45}{512}$		
$3d^2$	$\frac{3965}{46\,080}$	$\frac{2093}{46\,080}$	$\frac{1365}{46\,080}$	
$4f^2$	$\frac{184331}{3670016}$	$\frac{103275}{3670016}$	$\frac{69003}{3670016}$	$\frac{51051}{3670016}$

Equivalent electrons

Some valuable exact solutions can be obtained for equivalent electrons. These are interesting in their own right but also prove valuable as benchmarks for numerical calculations. For equivalent electrons the integrals (7.65) coincide and simplify to the form (see Problem 7.7)

$$F^k(nl;nl) = 2\int_0^\infty d\rho \int_0^\rho d\varrho \frac{\varrho^{k+2}}{\rho^{k-1}} [\tilde{R}_{nl}(\varrho)\tilde{R}_{nl}(\rho)]^2. \tag{7.66}$$

Note that this expression is positive definite, $F^k(nl;nl) > 0$. Changing to the variables $x = 2Z\rho/n$ and $y = 2Z\rho\varrho/n$ this can be rewritten as

$$F^k(nl;nl) = (2Z/n)\frac{2}{\mathcal{N}_{nl}^2}\int_0^\infty dx\, x^{2l+1-k}e^{-x}[L_{n-l-1}^{2l+1}(x)]^2 \int_0^x dy\, y^{2l+2+k}e^{-y}[L_{n-l-1}^{2l+1}(y)]^2. \tag{7.67}$$

Since $L_0^{2l+1}(x) \equiv 1$ further simplification occurs for the case $l = n-1$; i.e., for the configurations $1s^2$, $2p^2$, $3d^2$ and $4f^2$. In these cases the Coulomb integrals further simplify to

$$F^k(nl;nl) = (2Z/n)\frac{2}{\mathcal{N}_{nl}^2}\int_0^\infty dx\, x^{2l+1-k}e^{-x}\int_0^x dy\, y^{2l+2+k}e^{-y}. \tag{7.68}$$

These integrals are easily evaluated in *Mathematica*. For the configurations $1s^2$, $2p^2$, $3d^2$ and $4f^2$ the results are summarized in Table 7.2. Note that the following inequality is satisfied:

$$F^k(nl^2) < F^{k-2}(nl^2). \tag{7.69}$$

Importantly, this inequality holds for any radial wavefunction; i.e., also in the non-hydrogenic case. Note that Problem 7.8 is helpful in this context.

Problem 7.7. Derive Eq. (7.66).

Solution. Starting from Eq. (7.65a) and (7.64a) we find for equivalent electrons

$$F^k(nl;nl) = \int_0^\infty d\rho \int_0^\rho d\varrho \frac{\varrho^k}{\rho^{k+1}}[\tilde{\chi}_{nl}(\varrho)\tilde{\chi}_{nl}(\rho)]^2 + \int_0^\infty d\rho \int_\rho^\infty d\varrho \frac{\rho^k}{\varrho^{k+1}}[\tilde{\chi}_{nl}(\varrho)\tilde{\chi}_{nl}(\rho)]^2,$$

where $\tilde{\chi}_{nl}(\rho) = \rho\tilde{R}_{nl}(\rho)$. Next we change the order of integration of the second term

$$\int_0^\infty d\rho \int_\rho^\infty d\varrho \frac{\rho^k}{\varrho^{k+1}}[\tilde{\chi}_{nl}(\varrho)\tilde{\chi}_{nl}(\rho)]^2 = \int_0^\infty d\varrho \int_0^\varrho d\rho \frac{\rho^k}{\varrho^{k+1}}[\tilde{\chi}_{nl}(\varrho)\tilde{\chi}_{nl}(\rho)]^2.$$

This leads to the desired result by a change of dummy indices, $\rho \to \varrho$ and vice versa. □

Problem 7.8. Show that $U_F^k(\rho) > U_F^{k+1}(\rho)$.

Solution. We rewrite $U_F^k(\rho) - U_F^{k+1}(\rho)$ using the substitution $z = x/\rho$:

$$U_F^k(\rho) - U_F^{k+1}(\rho) = \rho^2 \int_0^1 \left[\tilde{R}_{nl}(\rho z)\right]^2 z^{k+2} (1-z)\, dz + \rho^2 \int_1^\infty \left[\tilde{R}_{nl}(\rho z)\right]^2 \left(\frac{1}{z}\right)^k (z-1)\, dz > 0$$

This is positive definite because

$$\left[\tilde{R}_{nl}(\rho z)\right]^2 z^{k+2} (1-z) \geq 0 \quad \text{for } 0 \leq z \leq 1$$
$$\left[\tilde{R}_{nl}(\rho z)\right]^2 (1/z)^k (z-1) \geq 0 \quad \text{for } z \geq 1. \qquad \square$$

Problem 7.9. Show that for equivalent electrons the exchange integral is positive definite, $\mathcal{K} > 0$.

Solution. For equivalent electrons we have $G^k(nl;nl) = F^k(nl;nl)$ and Eq. (7.59b) can be rewritten in the form

$$\mathcal{K}(nlm_l;nlm_l') = \sum_{k=0}^{\infty} b^k(lm_l;lm_l')F^k(nl;nl).$$

Since $b^k(lm_l;l'm_{l'}) \geq 0$ and $F^k(nl;nl) > 0$ for all values of k, we have $\mathcal{K}(nlm_l;nlm_l') > 0$. $\square$

7.4.3 The ground state of helium $^1S_0$

As a first example we analyze the ground state of ^{4}He, which consists of two electrons in the $1s^2$ configuration and $Z = 2$. The energy shift caused by the repulsion between the electrons in the same state is to first order in perturbation theory given by

$$\Delta\varepsilon_{1s} \simeq (1s, 1s|\mathcal{H}'|1s, 1s) = \mathcal{J}. \tag{7.70}$$

Using Eq. (7.59a) this can be written in the form

$$\Delta\varepsilon_{1s} = a^0(00;00)F^0(1s;1s). \tag{7.71}$$

Since $a^0(00;00) = 1$, see Problem 7.10, we find for the energy shift of one $1s$ electron by the other $1s$ electron

$$\Delta\varepsilon_{1s} = F^0(1s;1s) = \langle 1s|U_F^0(\rho)|1s\rangle. \tag{7.72}$$

Here $U_F^k(\rho)$ is the potential of direct screening of one of the $1s$ electrons by the other; i.e., $U_F^0(\rho) = U_{1s}(\rho)$ in the notation of Section 7.1.1. Substituting $\tilde{R}_{1s}(\rho) = Z^{3/2}2e^{-Z\rho}$ in Eq. (7.64a) for the wavefunction of the screening electron in a helium-like atom with nuclear charge Ze, we find with $k = 0$,

$$U_F^0(\rho) = \frac{1}{\rho}\int_0^\rho \left[\tilde{R}_{1s}(\varrho)\right]^2 \varrho^2 d\varrho + \int_\rho^\infty \frac{1}{\varrho}\left[\tilde{R}_{1s}(\varrho)\right]^2 \varrho^2 d\varrho = \frac{1}{\rho}\left[1 - e^{-2Z\rho}(1+Z\rho)\right] = U_{1s}(\rho). \tag{7.73}$$

Substituting this expression into Eq. (7.65a) we obtain with $Z = 2$ for the direct integral

$$\Delta\varepsilon_{1s} = F^0(1s;1s) = 32\int_0^\infty \left[1 - e^{-4\rho}(1+2\rho)\right] e^{-4\rho}\rho d\rho = \tfrac{5}{4}. \tag{7.74}$$

Note that this result also can be obtained directly from Table 7.2 because the $1s^2$ configuration involves only zero-order Laguerre polynomials. Restoring the dimension the energy shift is found to be $\Delta E_{1s} \simeq \frac{5}{2}hcR_\infty = 34.0$ eV, to be compared with the value 29.8 eV based on experiment. This shows that the perturbation theory overestimates the screening by 14% as was discussed in Section 7.1.1. It is straightforward to show with the aid of the closure approximation (see Section H.2) that the second order correction overshoots the proper value, which means that the multipole expansion (7.58) converges too slowly for an accurate determination of the screening.

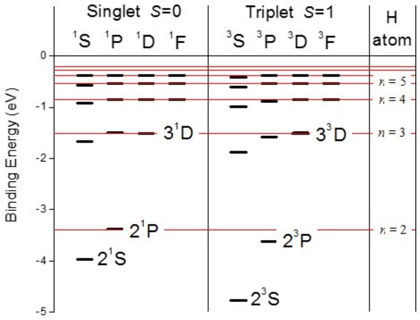

Figure 7.6: Energy-level diagram of the $1snl$ excited state configurations of helium. *Left*: singlet levels ($S = 0$) also known as *parahelium*; *Right*: triplet levels ($S = 1$) also known as *orthohelium.* Note that the highly-excited states give rise to hydrogenic energy levels, which means the screened nuclear charge is unity.

7.4.4 The ground state of metastable triplet helium $^3S_1$

The level diagram of the $1snl$ excited state configurations of helium is sketched in Fig. 7.6. Our special interest concerns the $1s2s$ configuration, a typical example of a lifted exchange degeneracy in a system with two non-equivalent electrons. The $^3S_1$ excited state of this configuration with total spin $S = 1$ is famous because it is metastable against de-excitation to the $^1S_0$ ground state with a radiative lifetime of 8000 s. The atom is called metastable triplet helium with the notation He*. Neglecting the electrostatic repulsion between the electrons the energy of the system is given by

$$E^{(0)}_{1s\,2s} = -hcR_\infty \left(\frac{Z^2}{n^2} + \frac{Z^2}{n'^2}\right) = -5hcR_\infty \qquad (Z = 2,\ n = 1,\ n' = 2)\,. \tag{7.75}$$

The radial distribution functions of the $\tilde{R}_{1s}(\rho)$ and $\tilde{R}_{2s}(\rho)$ radial wavefunctions are shown as the drawn lines in Fig. 7.7. The $2s$ orbital appears as a charged halo enclosing the $1s$ orbital with little overlap in the charge distribution. Therefore, in view of the discussion of electrostatic screening in Section 7.1.1 we expect this screening to be more or less maximal for the $2s$ outer electron ($Z_{2s} \simeq Z - 1$) and minimal for the $1s$ inner electron ($Z_{1s} \simeq Z$). The $2s$ charge distribution for the case $Z_{2s} = 1$ is shown as the dashed line in Fig. 7.7.

The energy shift caused by the repulsion between the electrons is to first order in perturbation theory given by Eq. (7.45), $\Delta E_- = \mathcal{J} - \mathcal{K}$, where in view of Eq. (7.60) only the $k = 0$ terms contribute to the direct and exchange integrals,

$$\mathcal{J} = (2hcR_\infty)\, a^0(00;00) F^0(1s;2s) \tag{7.76a}$$

$$\mathcal{K} = (2hcR_\infty)\, b^0(00;00) G^0(1s;2s). \tag{7.76b}$$

With Eqs. (7.79) and (7.80) we obtain $a^0(00;00) = b^0(00;00) = 1$. Substituting the expressions for the $\tilde{R}_{1s}(\rho)$ and $\tilde{R}_{2s}(\rho)$ hydrogenic wavefunctions we find, using Eqs. (7.64) with $k = 0$, for the $1s$ direct screening and the $1s2s$ exchange screening potentials

$$U^0_F(\rho) = (1/\rho)\left[1 - e^{-2Z\rho}(1 + Z\rho)\right] = U_{1s}(\rho) \tag{7.77a}$$

$$U^0_G(\rho) = (2/27)\,\sqrt{2} Z e^{-3Z\rho/2}\,[2 + 3Z\rho] = X_{1s2s}(\rho). \tag{7.77b}$$

Substituting these expressions into Eqs. (7.65) we obtain with $Z = 2$ for the direct and exchange

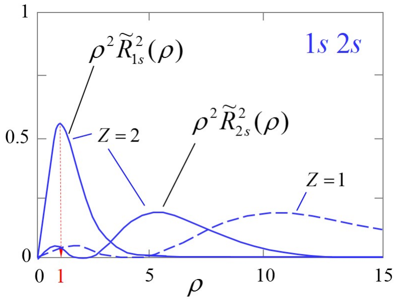

Figure 7.7: Radial distribution function for the $1s2s$ excited state configuration of the helium atom. In this case the effect of inflation is small because the $1s$ and $2s$ orbitals show little overlap. The dominant effect is screening, which reduces the effective charge of the nucleus for the $2s$ electron to the value $Z \approx 1$. In this case the $2s$ orbital inflates to more or less its value in the hydrogen atom.

radial integrals of the He* atom

$$F^0(1s;2s) = \int_0^\infty U_F^0(\rho)\left[\tilde{R}_{2s}(\rho)\right]^2\rho^2 d\rho = 34/81 \tag{7.78a}$$

$$G^0(1s;2s) = \int_0^\infty U_G^0(\rho)\tilde{R}_{1s}(\rho)\tilde{R}_{2s}(\rho)\rho^2 d\rho = 32/729. \tag{7.78b}$$

Hence, the energy shift is found to be $\Delta\varepsilon_{2s} = F^0(1s;2s) - G^0(1s;2s)$. Restoring the units this becomes $\Delta E_{2s} = (548/729)\,hcR_\infty = 10.2$ eV and the estimate for the energy of the state to first order in perturbation theory is $E^{(1)}_{1s\,2s} = E^{(0)}_{1s\,2s} + \Delta E_{\text{scr}} = -57.8$ eV. The experimental value is $E_{1s\,2s} = -59.2$ eV. Comparing to the energy -54.4 eV of the He$^+$ ion the state is calculated to be bound with an ionization energy of 3.4 eV. The experimental value for the ionization energy of ^{4}He* is 4.8 eV (see Fig. 7.6). Thus, like for the $1s^2$ configuration, also in the $1s2s$ case the perturbation theory underestimates the screening, 15.9% of 8.8 eV for ^{4}He*. For the singlet-triplet splitting we calculate $2\mathcal{K} = (64/729)\,2hcR_\infty = 2.39$ eV, to be compared with the experimental value $2\mathcal{K} = 0.80$ eV. The modest agreement is not surprising since the $\tilde{R}_{2s}(\rho)$ wavefunction does not have the long-range behavior corresponding to an effective nuclear charge $Z_{2s} = 1$. Obviously, this leaves room for a lot of improvement but this falls outside the scope of the course.

Problem 7.10. Show that for the configuration $ns\,n'l$ the a^k coefficient is given by

$$a^k(00;lm_l) = \begin{cases} 1 \text{ for } k = 0 \\ 0 \text{ for } k > 0 \end{cases}. \tag{7.79}$$

Solution. In view of Eqs. (7.60) $a^k(00,lm_l) = 0$ for $k > 0$. For $k = 0$ we have

$$a^k(00;lm_l) = (2l+1)\begin{pmatrix} 0\,0\,0 \\ 0\,0\,0 \end{pmatrix}^2 \begin{pmatrix} l\;0\;l \\ 0\,0\,0 \end{pmatrix}\begin{pmatrix} l & 0 & l \\ -m_l & 0 & m_l \end{pmatrix} = 1$$

because (see Appendix J)

$$\begin{pmatrix} 0\,0\,0 \\ 0\,0\,0 \end{pmatrix} = 1 \quad \text{and} \quad \sqrt{2l+1}\begin{pmatrix} l & 0 & l \\ -m_l & 0 & m_l \end{pmatrix} = (-1)^{-1}. \qquad \Box$$

Problem 7.11. Show that for the configuration $ns\,n'l$ the b^k coefficient is given by

$$(2l+1)b^k(00;lm_l) = \begin{cases} 1 \text{ for } k = l \\ 0 \text{ for } k \neq l \end{cases}. \tag{7.80}$$

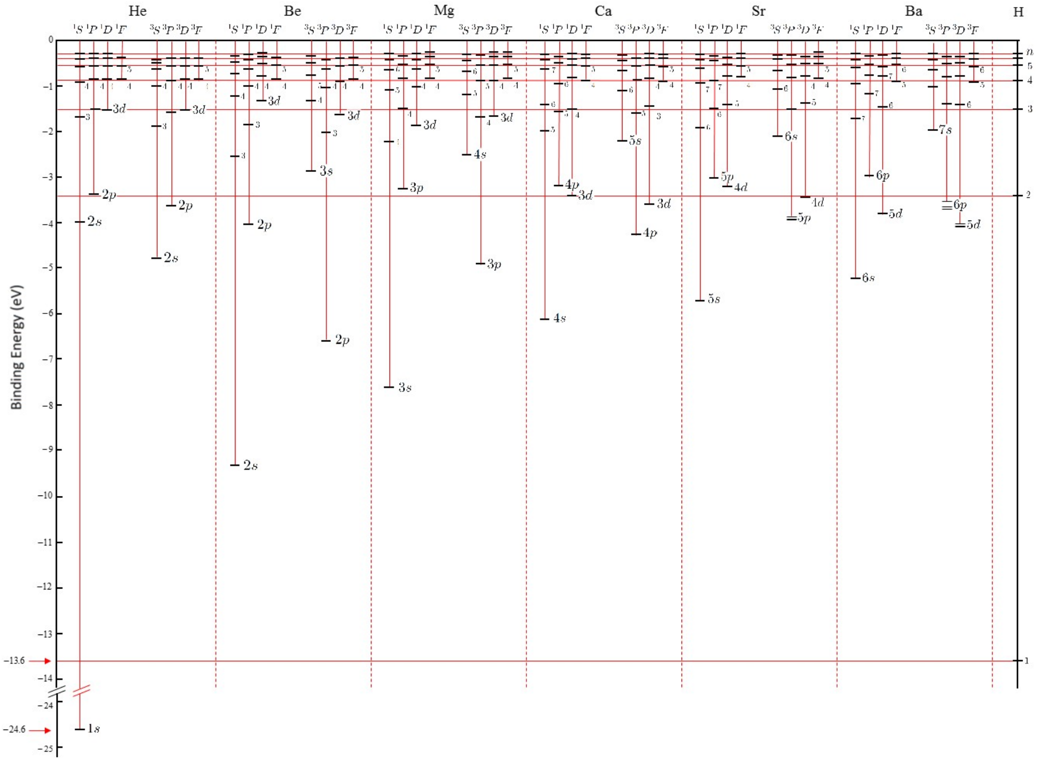

Figure 7.8: Energy levels of helium and helium-like atoms (the alkaline earth elements) for nl excitation of *one* of the s electrons from the ${}^1S_0$ ground state. The data are taken from the NIST Atomic Spectra Database Levels Data [66]. In the Sr data the fine-structure splitting of the $5\,{}^3P$ term is just visible in the plot; for Ba this is the case for both the $6\,{}^3P$ and $5\,{}^3D$ terms. Levels associated with two-electron excitations are not included in the diagram.

Solution. In view of Eqs. (7.60) $b^k(00, lm_l) = 0$ for $k \neq l$. For $k = l$ we have

$$b^k(00; lm_l) = (2l+1)\begin{pmatrix} 0 & l & l \\ 0 & 0 & 0 \end{pmatrix}^2 \begin{pmatrix} 0 & l & l \\ 0 & -m_l & m_l \end{pmatrix}^2 = \frac{1}{(2l+1)},$$

because (see Appendix J)

$$\sqrt{2l+1}\begin{pmatrix} 0 & l & l \\ 0 & -m_l & m_l \end{pmatrix} = (-1)^{l-m_l}\,. \qquad \square$$

7.4.5 Helium-like atoms - energy levels

It is instructive to compare the energy-level diagram of helium with those of other helium-like atoms. In Fig. 7.8 this is done for the alkaline-earth elements. The level energies are determined by optical spectroscopy. Note that the helium-like behavior is evident; in all cases we have a $n\,{}^1S_0$ electronic ground state and a similar structure of excited states featuring only singlet and triplet terms. The latter points to effective two-electron behavior. Apparently, the principal effect of the core electrons is to screen the nucleus. This shows up as a reduction of the ground-state binding energy with increasing Z. Aside from the strong similarities there are also important differences. For instance, only in the helium case ($n = 1$) we find a metastable $(n+1)\,{}^3S_1$ level (He*). In all other cases the lowest triplet term is $n\,{}^3P$ or even $n\,{}^3D$. The exceptional case of helium can be traced back to the non-existence of $1p$ orbitals. Optical transitions between singlet and triplet terms are referred to as *intercombination lines.* These lines are weak because the transitions are spin forbidden. The helium $2\,^3S_1$ state is special because the $1\,^1S_0 \leftrightarrow 2\,^3S_1$ transition is doubly forbidden (spin as well as dipole forbidden). With increasing Z some of the intercombination lines become weakly allowed. This has to do with the increasing importance of spin-orbit coupling as will be explained in Section 10.6 (crossover from LS coupling to jj coupling). The growing importance of fine-structure effects are even visible on the rough energy scale of Fig. 7.8, where the fine-structure splitting becomes just visible in the *strontium* ($Z = 38$) and *barium* ($Z = 56$) data.

8

Central field approximation for many-electron atoms

The description of atoms with more than two electrons builds on the concepts introduced for the helium atom in Chapter 7: *central symmetry*, *screening*, *Pauli principle* and *exchange*. Just as in the helium case also the Hamiltonian for many-electron atoms is invariant under space inversion as well as under rotation of the spatial coordinates about the origin; i.e., the parity of the electronic wavefunction as well as the total orbital angular momentum are conserved in time. Recalling from the helium discussion the concept of electrostatic screening of the nuclear charge and the convenience of the centrally symmetric mean field, we simply presume that also in the many-electron case central forces dominate the motion of the individual electrons. This *central field approximation* allows the separation of variables, which makes it possible to continue the practice of describing the atoms in terms of single-electron orbitals specified by the quantum numbers n and l. This means that the atomic state can be characterized by specifying the *electron configuration.* The configuration with the lowest energy (strongest binding) corresponds to the ground state. For hydrogenic atoms the possible configurations are: $1s$, $2s$, $2p$, $3s$, $3p$, $3d, \cdots$. For atoms with more than one electron the Pauli principle limits the occupation of the orbitals. In this way the helium configurations become $1s^2$, $1s2s$, $1s2p$, $2s^2, \cdots$, for lithium we have $1s^22s$, $1s^22p, \cdots$, and so forth. So, in the configuration we group the electrons into *shells* of *equivalent* electrons, where electrons are called equivalent if they carry the same quantum numbers n and l (irrespective of the magnetic quantum numbers m_l and m_s). A shell containing the maximum number of electrons consistent with the Pauli principle is called *closed* or *fully filled.*

As was established before, the Coulomb interaction dominates by orders of magnitude over all other terms in the atomic Hamiltonian ($\alpha^2 \approx 5 \times 10^{-5}$). Therefore, to calculate the ground state energy the electronic charge has to be distributed across the atom as accurately as possible. In atomic systems this is best done with the self-consistent mean field method (Hartree method) introduced in the previous chapter. Other approaches to search for the optimal charge distribution are *density-functional theory* and *potential-functional theory* [37]. These are variational methods in which the variation is not done at the level of the wavefunction but by varying the probability charge density or its potential field, respectively. The archetype of such statistical theories is the Thomas-Fermi method, which will be introduced in the present chapter. Density functional theory plays an important role in chemistry and condensed matter physics, more in general in the physics of many-body systems which are too big for an *ab initio* quantum mechanical approach like the self-consistent mean field method [64]. Interestingly, the evolution of the density-functional and potential-functional methods into a fundamental theory was remarkably slow. It took half a century before it became main stream in the 1980's (in particular for the modeling of heavy molecules) which may explain its modest role (if not absence) in traditional atomic physics textbooks.

In this chapter we explore the *central field* concept and will introduce the *central field approximation.* In Section 4.7 we already discussed how this concept can be used to describe *alkali-like* atoms, where a single valence electron surrounds the electronic core. In the present chapter we discuss four examples of central field approximations: the *non-interacting electron atom*, the *Thomas-Fermi model*, the *Hartree mean field method* and the *quantum-defect approach* of Bates and Damgaard. The central field approximation provides - in hindsight - the justification for treating the alkali atoms as *hydrogen-like* atoms as was done in previous chapters, in particular in discussing the hyperfine structure (Chapter 5).

8.1 Hamiltonian

The Hamiltonian for the principal structure of a N-electron atom is given by a generalization of the Hamiltonian (7.1)[1]

$$\mathcal{H}=\sum_{i=1}^{N}\left(-\frac{\hbar^2}{2m_e}\nabla_i^2-\frac{Ze^2}{4\pi\varepsilon_0 r_i}\right)+\frac{1}{2}\sum_{i,j}^{N}{}'\frac{e^2}{4\pi\varepsilon_0 r_{ij}}, \tag{8.1}$$

where the first sum is the Hamiltonian for noninteracting electrons, $\mathbf{r}_i$ the position of electron i relative to the atomic nucleus, $r_{ij}=|\mathbf{r}_i-\mathbf{r}_j|$ the distance between the electrons i and j, with $i,j\in\{1,\cdots,N\}$, and ε_0 is the electric permittivity of vacuum. The factor 1/2 in front of the double summation is to correct for double counting and the prime indicates that the case $i=j$ is excluded. For neutral atoms we have $N=Z$.

8.1.1 Central field approximation

Recalling the concept of screening of the nuclear charge as discussed for the helium atom we rewrite the Hamiltonian (8.1) in the form

$$\mathcal{H}=\sum_{i=1}^{N}\left(-\frac{\hbar^2}{2m_e}\nabla_i^2-\frac{Ze^2}{4\pi\varepsilon_0 r_i}+\mathcal{V}_{\mathrm{scr}}(r_i)\right)+\frac{1}{2}\sum_{i,j}^{N}{}'\frac{e^2}{4\pi\varepsilon_0 r_{ij}}-\sum_{i=1}^{N}\mathcal{V}_{\mathrm{scr}}(r_i), \tag{8.2}$$

where for each electron i we both added and subtracted a *centrally symmetric* potential energy term $\mathcal{V}_{\mathrm{scr}}(r_i)$, which can be regarded as a generalization of the screening potential (7.13) introduced for helium. By this procedure the Hamiltonian separates into two parts, $\mathcal{H}=\mathcal{H}_{\mathrm{CF}}+\mathcal{H}'$.

The first term,

$$\mathcal{H}_{\mathrm{CF}}\equiv\sum_{i=1}^{N}\left(-\frac{\hbar^2}{2m_e}\nabla_i^2+\mathcal{V}_{\mathrm{CF}}(r_i)\right), \tag{8.3}$$

is called the *central field Hamiltonian.* It is the sum of N one-electron Hamiltonians, a generalization of the Hamiltonian (7.5) but it accounts for screening because

$$\mathcal{V}_{\mathrm{CF}}(r_i)=-\frac{Ze^2}{4\pi\varepsilon_0 r_i}+\mathcal{V}_{\mathrm{scr}}(r_i)=-\frac{e^2}{4\pi\varepsilon_0}\frac{Z_{\mathrm{eff}}(r_i)}{r_i} \tag{8.4}$$

is the *potential energy* of electron i in the (centrally symmetric) *electrostatic potential* of the nucleus screened by the other $(N-1)$ electrons. It is the *effective central field potential* for the N-electron problem, a generalization of the Eq. (7.17) used for helium. The quantity $Z_{\mathrm{eff}}(r_i)$ is the *effective nuclear charge* for electron i at distance r_i from the nucleus introduced in Eq. (4.101). Close to the nucleus the screening is negligible and $\mathcal{V}_{\mathrm{CF}}(r)$ must approach the potential energy of an electron in

---

[1] In the literature one finds two equivalent notations for the sum over all *different* pairs with $i,j\in\{1,\cdots N\}$:

$$\tfrac{1}{2}\sum_{i,j=1}^{N}{}'\equiv\sum_{i>j}^{N}.$$

Here the prime indicates the exclusion of the terms $i=j$ and the factor $\frac{1}{2}$ corrects for double counting. Alternatively, one can sum over all pairs with $i>j$.

the unscreened nuclear charge Ze. Far from the nucleus all but the Rydberg charge $Z_c\, e$ is shielded. This imposes onto the $Z_{\text{eff}}(r)$ the boundary conditions $\lim_{r\to 0} Z_{\text{eff}}(r) = Z$ and $\lim_{r\to\infty} Z_{\text{eff}}(r) = Z_c$, with $Z_c = 1$ for neutral atoms.

The second term of Eq. (8.2),

$$\mathcal{H}' \equiv \frac{1}{2}\sum_{i,j=1}^{N}{}' \frac{e^2}{4\pi\varepsilon_0 r_{ij}} - \sum_{i=1}^{N} \mathcal{V}_{\text{scr}}(r_i), \tag{8.5}$$

represents the residual Coulomb interactions that cannot be included in the *centrally symmetric* screening field. This term can be regarded as a (non-central) perturbation on $\mathcal{H}_{\text{CF}}$ and accounts for *Coulomb correlations* in the relative motion of the electrons. For optimal screening potentials this perturbation is minimal. Neglecting $\mathcal{H}'$ we obtain the *central field approximation*,

$$\mathcal{H} = \mathcal{H}_{\text{CF}}. \tag{8.6}$$

A first estimate for the importance of the Coulomb correlations can be obtained by perturbation theory with respect to the central field solutions.

8.2 Non-interacting electron atoms

A lot can already be said about many-electron atoms by simply ignoring the interaction between the electrons. For *non-interacting-electron* atoms only the Coulomb interaction with the nucleus remains and the atoms can be constructed using configurations of hydrogenic wavefunctions. The configuration energies are determined by the energies of the single-electron hydrogenic levels. The Pauli principle is included to assure that no orbital level is occupied more than twice. Many of the configurations will be degenerate but adding electrons in order of increasing orbital angular momentum the Z dependence of the configuration energy has the following order:

$$\begin{array}{l}
[\text{H}] = 1s \qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad [\text{He}] = 1s^2 \\
[\text{Li}] = [\text{He}]2s,\ [\text{Be}] = [\text{He}]2s^2,\ [\text{Bo}] = [\text{He}]2s^2 2p^1, \cdots, [\text{Ne}] = [\text{He}]2s^2 2p^6 \\
[\text{Na}] = [\text{Ne}]3s,\ [\text{Na}] = [\text{Ne}]3s^2,\ [\text{Al}] = [\text{Ne}]3s^2 3p^1,\ \cdots, [\text{Ar}] = [\text{Ne}]3s^2 3p^6\,.
\end{array}$$

This is in agreement with the periodic system of Mendeleev (see Table A.1) but at $Z = 18$ this agreement ends. At $Z = 19$, rather than the expected configuration

$$[\text{Ne}]3s^2 3p^6 3d$$

we find in the periodic system [K] = [Ar]$4s$. In this respect only the first three rows of the periodic table show the character of non-interacting-electron atoms. Of course we could try to add fine structure corrections but such refinements makes no sense because even the dominant corrections (electrostatic repulsion and exchange) are not included.

Despite the obvious shortcomings, non-interacting electron atoms provide valuable information about the scaling of atomic properties with Z. Since the degeneracy of states of given principal quantum number is n^2 - see Eq. (2.34) - the total number of electrons in *closed shells*, N, can be expressed in terms of $n_{\max}$, which is the principal quantum number of the highest occupied shell,

$$N = \sum_{n=1}^{n_{\max}} 2n^2 = \tfrac{1}{3} n_{\max}(n_{\max}+1)(2n_{\max}+1). \tag{8.7}$$

For neutral atoms the number of electrons is equal to the number of protons in the nucleus,

$$N = Z. \tag{8.8}$$

Along similar lines we can obtain an expression for the total binding energy of *closed shell* atoms. Using Hartree atomic units we calculate

$$-\varepsilon=\sum_{n=1}^{n_{\max}}2n^2\frac{Z^2}{2n^2}=Z^2n_{\max}. \tag{8.9}$$

Eliminating $n_{\max}=\varepsilon/Z^2$ from Eqs. (8.7) and (8.9) we can express ε as a function of N and Z (see Problem 8.1)

$$-\varepsilon/Z^2=-\tfrac{1}{2}+(3N/2)^{1/3}+\tfrac{1}{12}(3N/2)^{-1/3}+\cdots. \tag{8.10}$$

Comparing this expression with a numerical inversion of Eq. (8.7) we find that approximating ε/Z^2 by the first three terms of the expansion is accurate to the ppm level for $N\geq 2$; i.e., the three-term approximation holds for all many-electron atoms or ions of the periodic system. We recall that Eq. (8.10) was derived for closed shell atoms but, as $n_{\max}$ is eliminated from the expressions, it also offers an interpolation procedure to interpolate for half-filled shells. For *neutral* atoms ($N=Z$) Eq. (8.10) becomes

$$-\varepsilon=-\tfrac{1}{2}Z^2+c_{7/3}\,Z^{7/3}+c_{5/3}\,Z^{5/3}+\cdots, \tag{8.11}$$

where $c_{7/3}=(3/2)^{1/3}\approx 1.145$ and $c_{5/3}=(3/2)^{-1/3}/12\approx 7.280\times 10^{-2}$. For instance, for the ground state of ^{4}He we calculate $\epsilon=-4.00012$ Hartree, which is already an excellent approximation of the exact value (-4 Hartree for non-interacting electrons). It only gets better for larger Z.

Problem 8.1. Derive the expansion (8.10).

Solution. We first rewrite the sum (8.7) in the form

$$N=\tfrac{2}{3}(n_{\max}+\tfrac{1}{2})^3-\tfrac{1}{6}(n_{\max}+\tfrac{1}{2}),$$

which is equivalent to $n_{\max}+\frac{1}{2}=(3N/2)^{1/3}\left[1+\frac{1}{4}(n_{\max}+\frac{1}{2})/(3N/2)\right]^{1/3}$. Expanding the cubic root we obtain

$$n_{\max}=-\tfrac{1}{2}+(3N/2)^{1/3}+\tfrac{1}{12}(n_{\max}+\tfrac{1}{2})\,(3N/2)^{-2/3}+\cdots.$$

Iterating $n_{\max}$ we obtain the desired expression. □

8.3 The statistical atom

8.3.1 Thomas-Fermi central field

The concept of a *screened Coulomb potential* may be intuitively attractive from the physical point of view, properly defining it mathematically is another matter. A source of inspiration in this context is the mean field approach introduced for two-electron atoms in Chapter 7. For heliogenic atoms the potential energy of one $1s$ electron in the Coulomb field of the nucleus screened by the other $1s$ electron is given (in SI units) by

$$\mathcal{V}_{\mathrm{CF}}(r)=-\frac{1}{4\pi\varepsilon_0}\frac{Ze^2}{r}+\frac{1}{4\pi\varepsilon_0}\frac{e^2}{r}\left[1-(1+Z\rho)e^{-2Z\rho}\right] \tag{8.12}$$

with $\rho=r/a_0$ and $Z=2$ for the helium atom. This expression is obtained by putting one electronic charge ($-e$) in the electrostatic scalar potential

$$\varphi_{\mathrm{CF}}(r)=\frac{1}{4\pi\varepsilon_0}\frac{e}{r}\left[(Z-1)+(1+Z\rho)e^{-2Z\rho}\right]. \tag{8.13}$$

This scalar potential can be written as the product of a pure Coulomb field and a monotonically decreasing *screening function*,

$$\varphi_{\mathrm{CF}}(r)=\frac{1}{4\pi\varepsilon_0}\frac{Ze}{r}F(r). \tag{8.14}$$

Note that that $F(r)$ is *dimensionless.* Recalling the definitions of the *effective nuclear charge* $Z_{\text{eff}}(r)$ and the *screening charge* $\sigma_{\text{eff}}(r)$, see Section 7.1.1, the screening function can be expressed in the form

$$F(r)=\frac{Z_{\text{eff}}(r)}{Z}=\frac{Z-\sigma_{\text{eff}}(r)}{Z}. \tag{8.15}$$

This function falls off from *unity* (no screening) close to the nucleus, $\lim_{r\to0}F(r)=1$, to $(Z-Z_c)/Z$ (full screening by $Z-Z_c$ electrons) at large distance, $\lim_{r\to\infty}F(r)=(Z-Z_c)/Z$. For neutral atoms the Rydberg charge is unity and the limiting value at large distance becomes $(Z-1)/Z$ (full screening by $Z-1$ electrons), with $\lim_{r\to\infty}F(r)=1/2$ (full screening by 1 electron) for helium ($Z=2$).

Although Eq. (8.13) has the proper limiting behavior for screening by a single $1s$ electron in heliogenic atoms there is no reason to expect that the charge distribution of the $1s$ orbital is necessarily the best choice to describe the screening in general. Insight into screening in N-electron atoms can be obtained with the quantum-statistical method of Llewellyn Thomas and Enrico Fermi. Thomas and Fermi imposed the condition that the semi-classical distribution of charge within the atom be in accordance with the *Poisson equation* of classical electrostatics [109, 41],

$$\Delta\varphi(\mathbf{r})=-\varrho_e(\mathbf{r})/\varepsilon_0 \qquad r\neq0. \tag{8.16}$$

Here $\varphi(\mathbf{r})$ represents the electrostatic scalar potential at position $\mathbf{r}$ and $\varrho_e(\mathbf{r})$ is the *charge density* of the electron cloud surrounding the nucleus, $\varrho_e(\mathbf{r})=-e\,n(\mathbf{r})$, with $n(\mathbf{r})$ being the *Thomas-Fermi number density* of electrons. For *neutral* atoms we have $\int n(\mathbf{r})d\mathbf{r}=Z$. For central symmetry, $\varrho_e(\mathbf{r})=\varrho_e(\rho)/4\pi$, it is advantageous to turn to spherical coordinates and to remove the angular dependence by integrating both sides of the Poisson equation over θ and ϕ. In this way we obtain (cf. Sections 1.2.1 and 1.1.8)

$$\frac{1}{r}\frac{\partial^2}{\partial r^2}r\varphi_{\text{CF}}(r)=-\varrho_e(r)/\varepsilon_0 \qquad r\neq0. \tag{8.17}$$

Note that the *Thomas-Fermi* approach does not distinguish between spectator and screening electrons, it includes *all* Z electrons in the screening.

The idea of calculating screening by distributing the electronic charge according to a probability distribution is well known from classical physics (*space charge* distribution). It is expected to work best for many electron atoms in which $n(\mathbf{r})$ can be obtained as the average density of electrons at position $\mathbf{r}$. Interestingly, again the helium atom provides us with an indication that this approach can be stretched to atoms with a small number of electrons because the effective electrostatic potential (8.13), derived for screening by only a single $1s$ electron, turns out to satisfy the Poisson equation if one uses for the average density the probability density of the electronic wavefunction, $n(\mathbf{r})=|\psi_{1s}(\mathbf{r})|^2$ - see Problem 8.2.

Problem 8.2. Show that the effective electrostatic potential

$$\tilde{\varphi}_{\text{CF}}(\rho)=(1/\rho)\left[(Z-1)+(1+Z\rho)e^{-2Z\rho}\right]$$

derived for a $1s$ electron and a nuclear charge Ze satisfies the Poisson equation of electrostatics.

Solution. In atomic units, the Poisson equation is given by $\Delta\tilde{\varphi}_{\text{CF}}=-4\pi\tilde{\varrho}_e$, where Δ is the laplacian with respect to $\boldsymbol{\rho}$, $\tilde{\varphi}_{\text{CF}}(\boldsymbol{\rho})$ the scalar potential and $\tilde{\varrho}_e(\boldsymbol{\rho})$ the charge density, in atomic units. In particular, the charge density of the electron cloud is given by $\tilde{\varrho}_e(\boldsymbol{\rho})=-a_0^3n(\mathbf{r})$ atomic units. For the $1s$ electron the charge distribution is spherically symmetric and in atomic units given by $\tilde{\varrho}_e(\rho)=-\tilde{R}_{1s}^2(\rho)/4\pi=-4e^{-2Z\rho}Z^3/4\pi$, where $\rho=r/a_0$. In view of the spherical symmetry the angular and radial variables separate and (using the same approach as taken for the derivation of the 1D Schrödinger equation) the Poisson equation becomes

$$\nabla^2\tilde{\varphi}_{\text{CF}}=\frac{\partial^2\tilde{\varphi}_{\text{CF}}}{\partial\rho^2}+\frac{2}{\rho}\frac{\partial\tilde{\varphi}_{\text{CF}}}{\partial\rho}=\frac{1}{\rho}\frac{\partial^2}{\partial\rho^2}\rho\,\tilde{\varphi}_{\text{CF}}=4e^{-2Z\rho}Z^3.$$

Integrating twice and putting the boundary condition $\lim_{\rho\to0}\rho\,\tilde{\varphi}_{\text{CF}}(\rho)=Z$ (no screening near the nucleus) and $\lim_{\rho\to\infty}\rho\,\tilde{\varphi}_{\text{CF}}(\rho)=Z-1$ (full screening by $Z-1$ electrons) we obtain the given expression for the electrostatic potential $\tilde{\varphi}_{\text{CF}}(\rho)$. □

8.3.2 Thomas-Fermi model

Thomas and Fermi applied the central field concept in the *Thomas-Fermi model* for the atom [109, 41]. One may argue that this model is merely of historical interest because it does not offer the precision that can be obtained by advanced variational methods like the Hartree-Fock method (cf. Section 10.2.3). However, aside from being the first example of a density functional method, the Thomas-Fermi model continues to be educationally valuable for at least three reasons: (a) it points to the existence of *Madelung ordering* in the periodic system of the elements, often emphasized in elementary texts on chemistry; (b) it offers an Ansatz for more advanced variational methods; (c) it attracts renewed interest in view of the application of the Thomas-Fermi approximation in the mean-field description of ultracold atomic gases [83].

The Thomas-Fermi model is the simplest model that accounts for the quantum-statistical correlations of the electrons in many-electron atoms. It is a semi-classical model in which the electron cloud is represented by a degenerate Fermi gas at zero temperature. The cloud is supposed to be *centrally symmetric* and to have a well-defined *local density* $n(r)$, distributed in accordance with the Poisson equation (8.16). The use of quantum statistics in combination with a local density approximation is known as the *Thomas-Fermi approximation.* Because the electron gas is fully degenerate its compressibility is determined by the Pauli exclusion principle. Together with the *space charge* of the electron cloud this fixes the total number of electrons that can be contained in the Coulomb potential of the nucleus. Being fully degenerate the phase-space density is 2 electrons per unit volume of phase space - $(2\pi\hbar)^3$; i.e., wherever the density in configuration space is high the density in momentum space has to be low and *vice versa.* For instance, as close to the nucleus the electron density is high, the density in momentum space has to be low. This means that the momentum spread has to be large, which is possible without ionization because (close to the nucleus) the ionization energy is high. On the other hand, far from the nucleus the ionization energy is small and because the electrons are bound also the uncertainty in momentum has to be small. This means that the density in momentum space has to be high, which is possible because (far from the core) the electron density is small.

The screening function, $F(r)$, can be related to local density, $n(r)$, through the *chemical potential* of the atom, μ. The latter is the energy required to add one electron to the electron cloud at zero temperature. In the Thomas-Fermi approximation the chemical potential is taken to be constant across the atom. It can be expressed as the sum of the local kinetic- and potential energy contributions,

$$\mu = \frac{\hbar^2}{2m_e}\left[3\pi^2 n(r)\right]^{2/3} - e\varphi_{\mathrm{CF}}(r). \tag{8.18}$$

The kinetic energy of the least-bound electron at distance r from the nucleus is approximated by the Fermi energy of a degenerate Fermi gas of density $n(r)$; the potential energy of this electron is determined by the screening of the nucleus by the centrally symmetric charge distribution

$$\varrho_e(r) = -en(r). \tag{8.19}$$

Starting from a bare nucleus of charge Ze we can supply electrons to the electron cloud until $\mu = 0$. Hence, the electronic density distribution of a *neutral* atom follows from Eq. (8.18) by setting $\mu = 0$,

$$n(r) = \frac{1}{3\pi^2}\left[\frac{2m_e}{\hbar^2}e\varphi_{\mathrm{CF}}(r)\right]^{3/2}. \tag{8.20}$$

At this point we impose the Poisson equation for the centrally symmetric case - see Eq. (8.17)

$$\frac{1}{r}\frac{\partial^2}{\partial r^2}r\varphi_{\mathrm{CF}}(r) = en(r)/\varepsilon_0. \tag{8.21}$$

To assure the absence of screening near the nucleus we require $\lim_{r\to 0} r\varphi_{\mathrm{CF}}(r) = Z$. For neutral atoms we require full screening of the nucleus at large distance, $\lim_{r\to\infty} r\varphi_{\mathrm{CF}}(r) = 0$. By substituting

Eq. (8.14) into Eqs. (8.21) and (8.20) we obtain two relations between the screening function and the local density,

$$\frac{Z}{r}\frac{\partial^2}{\partial r^2}F(r) = 4\pi n(r) \quad \text{and} \quad n(r) = \frac{1}{3\pi^2 a_0^3}\left[2a_0\frac{Z}{r}F(r)\right]^{3/2}. \tag{8.22}$$

Eliminating $n(r)$ from these equations and changing to new variables ($F \to \check{F}$, $r \to x$) we obtain the *Thomas-Fermi equation* for screening,

$$\check{F}'' = x^{-1/2}\check{F}^{3/2}. \tag{8.23}$$

Here $\check{F}(x)$ is called the *Thomas-Fermi function* and $x = bZ^{1/3}\rho$ the *Thomas-Fermi variable*, with $b = 2(\frac{4}{3}\pi)^{2/3} \simeq 1.13$. The function $\check{F}(x)$ has to satisfy the boundary conditions $\lim_{x\to 0}\check{F}(x) = 1$ (no screening near nucleus) and $\lim_{x\to\infty} x\check{F}(x) = 0$ (normalizable density distribution). The normalization condition implies that for $x \to \infty$ the screening function decays sufficiently fast. This requirement is stronger than the condition of full screening at large distance. Setting $\check{F} = 1$ in the r.h.s. of Eq. (8.23) we find the following functional behavior near the nucleus ($x \ll 0$):

$$\check{F}(x) = 1 - Bx + Cx^{3/2} + \cdots. \tag{8.24}$$

The Thomas-Fermi equation is a non-linear second-order differential equation. As it cannot be solved analytically $F(x)$ has to determined numerically, which is a simple task in *Mathematica*. The boundary conditions are satisfied for $B = 1.58807097266316554$. The full numerical result is shown in Fig. 8.1. Note that $\check{F}(x)$ is monotonically decreasing, as it should be for a screening function. The Thomas-Fermi function represents a *universal scaling solution*. The function is *universal* because $\check{F}(x)$ is independent of Z; i.e., the shape of the function is the same for all atoms. It is a *scaling solution* because the variable x depends on $Z^{1/3}$; i.e., the radial profile of the effective charge, $\check{Z}_{\text{eff}}(x) = Z\check{F}(x)$, scales with the atomic size. In atomic units this expression becomes

$$\check{F}(x) = \tilde{F}(\rho) = 1 - bB\,Z^{1/3}\rho + C\,Z^{1/2}(b\rho)^{3/2} + \cdots. \tag{8.25}$$

The corresponding radial distribution function is (see Fig. 8.1)

$$\rho^2\tilde{n}(\rho) = \frac{\rho^2}{3\pi^2 a_0^3}\left[2\frac{Z}{\rho}\tilde{F}(\rho)\right]^{3/2} \sim Z^{4/3}x^2\left[F(x)/x\right]^{3/2}. \tag{8.26}$$

Calculating the screening potential using Eqs. (7.17)-(7.20) we find for $\rho \ll 1$

$$U_{\text{scr}}(\rho) = \frac{Z}{\rho}[bB\,Z^{1/3}\rho + C\,Z^{1/2}(b\rho)^{3/2} + \cdots] = 1.79\,Z^{4/3} + b^{3/2}C\,Z^{3/2}\rho^{1/2} + \cdots. \tag{8.27}$$

As in the case of the self-consistent mean field (derived in Chapter 7 for the helium atom in its ground state) the leading term is a constant. It represents the electrostatic repulsion energy of an electron close to the nucleus with the surrounding electronic cloud. Comparing Eqs. (8.27) and (7.16) we note that in the Thomas-Fermi case this electrostatic repulsion energy is larger, $1.79\,Z^{4/3} > Z$. Apparently, the charge is distributed closer to the nucleus.

8.3.3 Schrödinger equation for one-electron in the presence of screening

It is of particular interest to analyze how the motion of an electron changes when we add isotropic screening to a Coulomb potential. As the potential remains central all we have to do is replace Z by $Z_{\text{eff}}(\rho)$ in Eq. (2.18); i.e., in Hartree atomic units the 1D-Schrödinger equation becomes

$$\tilde{\chi}_l'' + 2\left[Z_{\text{eff}}(\rho)/\rho - l(l+1)/2\rho^2 - \varepsilon_l\right]\tilde{\chi}_l = 0. \tag{8.28}$$

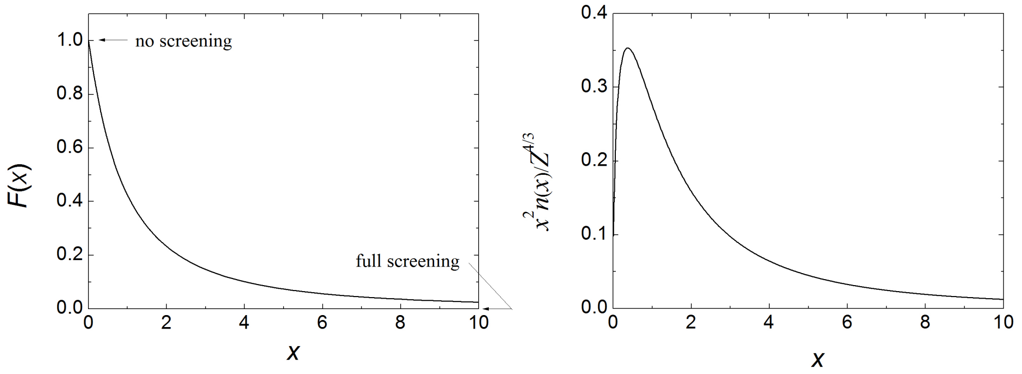

Figure 8.1: The Thomas-Fermi function (left) and the corresponding radial distribution function (right).

For the limiting behavior of the effective charge we require $\lim_{\rho\to\infty} Z_{\text{eff}}(\rho) = 1$ and $\lim_{\rho\to 0} Z_{\text{eff}}(\rho) = Z$. These conditions lead to the same limiting expressions for the radial wave equation as in the case of hydrogenic atoms. Thus, using the procedure of Section 2.1.2, we introduce a function $\tilde{w}_l(\rho)$ to connect the short-range tail to the long-range tail of the hydrogenic wavefunction,

$$\tilde{\chi}_l(\rho) = \rho^{l+1} e^{-\rho\sqrt{2\varepsilon_l}}\,\tilde{w}_l(\rho), \tag{8.29}$$

with the condition that $\tilde{w}_l(0) = 1$ and $\tilde{\chi}_l(\rho)$ be algebraic for $\rho \to \infty$. Substituting this expression into Eq. (8.28) we find

$$\rho\tilde{w}_l'' + 2[(l+1) - \sqrt{2\varepsilon_l}\rho]\tilde{w}_l' + 2[Z_{\text{eff}}(\rho) - (l+1)\sqrt{2\varepsilon_l}]\tilde{w}_l = 0. \tag{8.30}$$

This is just Eq. (2.22) with Z replaced by $Z_{\text{eff}}(\rho)$. In the present case the screening by the $Z-1$ "other" electrons of the atom is accounted for by the functional dependence of $Z_{\text{eff}}(\rho)$. Of course, the art is to find the best expression for $Z_{\text{eff}}(\rho)$. The price to pay is that the 1D-Schrödinger equation can no longer be solved analytically.

Fortunately, already a lot can be learned by analyzing the effective potential energy

$$U_l(\rho) = -\frac{Z}{\rho} Z_{\text{eff}}(\rho)/Z + \frac{l(l+1)}{2\rho^2}, \tag{8.31}$$

which should at least have a single bound state. The simplest one is to choose for $Z_{\text{eff}}(\rho)/Z$ simply the universal (Z independent) Thomas-Fermi screening function $\tilde{\Phi}(\rho)$,

$$U_l(\rho) = -\frac{Z}{\rho}\tilde{F}(\rho) + \frac{l(l+1)}{2\rho^2}. \tag{8.32}$$

This expression has the obvious flaw of overestimating the screening because it includes self-screening (note that $Z_{\text{eff}}(\rho) \to 0$ for $\rho \to \infty$). However, this error will decrease with increasing Z, so the approximation is useful at least for large atoms. For $l > 0$ this potential energy curve is always positive unless Z is sufficiently large. So we can determine the value of Z at which the curve starts to run negative by setting $U_l(\rho) = 0$. Changing to the Thomas-Fermi variable $x = bZ^{1/3}\rho$, with $b \simeq 1.13$, the potential energy curve has a local minimum which touches on the zero energy axis at

$$Z(x) = \frac{4}{3\pi}\left[\frac{l(l+1)}{x\check{F}(x)}\right]^{3/2}. \tag{8.33}$$

This function has a universal (l independent) minimum at $x \approx 2.14$; i.e., $x\check{F}(x) \approx 0.486$. For $l = 1, 2, 3, 4$ we calculate $Z = 3.5$, 18.4, 52, 112, respectively. These values represent lower bounds, for actual binding Z has to be somewhat larger. From the periodic table we know that the experimental Z values at which the first p, d and f appear are $Z = 5$, 21, 58. Further, g electrons do not appear at all in the range of elements shown in the periodic system. Hence, already with this simple model the trend emerges satisfactorily. Solving the radial equation numerically we find $Z = 6.6$, 26, 66, 134. In other words the model overestimates the charge required for binding, which is not surprising because the model overestimates the screening. Moreover the model also neglects the exchange, which also implies an overestimate of the screening. In any case the model exposes the relevant physics and is rewarding in the sense that it shows the *Madelung order* in the appearance of angular momentum in the periodic system.

8.3.3.1 Quantum defects

A simple model of screening explaining the properties of the quantum defect can be obtained by writing the effective principal quantum number in the form

$$n_l^* = n' + l^* + 1. \tag{8.34}$$

Here n' is the radial quantum number introduced in Section 2.1.2 and l^* is defined by

$$l^* \equiv l - \delta_l. \tag{8.35}$$

The form (8.34) suggests to interpret n_l^* as the principal quantum number of the solutions of the following 1D Schrödinger equation

$$\tilde{\chi}_{l^*}'' + 2\left[Z_c/\rho - l^*(l^*+1)/2\rho^2 - \kappa_{l^*}^2\right]\tilde{\chi}_{l^*} = 0. \tag{8.36}$$

To reveal the physics behind this model we rewrite Eq. (8.36) in the form

$$\tilde{\chi}_{l^*}'' + 2\left[Z_c/\rho + A(Z)/2\rho^2 - l(l+1)/2\rho^2 - \kappa_{l^*}^2\right]\tilde{\chi}_{l^*} = 0, \tag{8.37}$$

where $A(Z)$ is a Z-dependent constant following from the relation

$$A(Z) - l(l+1) = -l^*(l^*+1). \tag{8.38}$$

Comparing Eq. (8.37) with the 1D Schrödinger equation (2.18) we note that the Coulomb interaction from the hydrogenic equation is replaced by an screened Coulomb interaction of the form

$$Z_l(\rho)/\rho = \frac{1}{\rho}[Z_c + \tfrac{1}{2}A(Z)/\rho]. \tag{8.39}$$

Far from the nucleus, for $\rho \gg \frac{1}{2}A(Z)/Z_c$, the effective charge $Z_l(\rho)$ approaches the Rydberg charge, $Z_l(\rho) \to Z_c$, exactly as we expect for screening. On the other hand, for $\rho \to 0$ the effective charge diverges which is nonphysical. However, this objection is of little consequence for our purpose because the valence orbitals of alkali atoms hardly probe the region close to the nucleus (in particular those with nonzero angular momentum). In any case the model shows that, in the presence of screening, states of given n but differing in l are *nondegenerate*, unlike in the hydrogenic case. Solving for δ_l we find

$$\delta_l = \tfrac{1}{2}(2l+1) \pm \tfrac{1}{2}\sqrt{(2l+1)^2 - 4A(Z)}. \tag{8.40}$$

For small $A(Z)$ the decaying branch may be approximated by

$$\delta_l \simeq \frac{A(Z)}{2l+1}, \tag{8.41}$$

which shows that for given Z the quantum defect δ_l decreases for increasing l as observed in experiment.

8.4 Hartree equations

Another way to deal with screening of the nuclear charge by the core electrons is the self-consistent mean field method introduced by Hartree in 1928 [56, 57]. In this section we derive the Hartree equations with the aid of the *variational principle* as was first demonstrated by Fock and by Slater in 1930 [102, 43]. We turn to (Hartree) atomic units by setting $m_e = e = \hbar = 1/4\pi\varepsilon_0 = 1$ in the Hamiltonian (8.1),

$$\mathcal{H} = \sum_{i=1}^{N} h_0^{(i)} + \tfrac{1}{2}\sum_{k,l=1}^{N}{}' \frac{1}{\rho_{kl}}. \tag{8.42}$$

Here we adopted the notation introduced for helium in which

$$h_0^{(i)} = -\tfrac{1}{2}\boldsymbol{\nabla}_i^2 - \frac{Z}{\rho_i} \tag{8.43}$$

represents the Schrödinger Hamiltonian of electron i in the bare field of the nucleus - see Eq. (7.9). Recalling the use of product wavefunctions for the description of the ground state of the helium atom we again look for ground state solutions of the Schrödinger equation in the form of a product state of single-electron orbitals. This is the approach of Hartree [56, 57]. In Dirac notation the product state is written as

$$|\psi_u) = |u_1, \cdots u_N) \equiv |u_1\rangle_1 \otimes |u_2\rangle_2 \otimes \cdots |u_N\rangle_N\,, \tag{8.44}$$

where particle 1 is in state u_1, particle 2 in state u_2, *etc.*; by convention the state of particle 1 always appears at the first (most left) position, the state of particle 2 always at the second position, *etc.*. Sometimes, when addressing a subset of the particles, we cannot use this implicit convention and attach the particle index and ordering explicitly,

$$|u_\kappa, u_\nu)_{i,j} \equiv |u_\kappa\rangle_i \otimes |u_\nu\rangle_j\,. \tag{8.45}$$

The indices κ and ν are called *state* indices, and i and j *particle* indices. In the product state (8.44) each electron is assigned a particular orbital in accordance with the electron configuration. Exchange effects are left out of consideration. This is of course an approximation but irrelevant for our goal of introducing the Hartree method. To first order in perturbation theory the energy of the N-electron state $|\psi_u)$ is given by

$$\varepsilon(u_1, \cdots u_N) = (\psi_u|\mathcal{H}|\psi_u) = \sum_{i=1}^{N}\langle u_i|h_0^{(i)}|u_i\rangle_i + \tfrac{1}{2}\sum_{k,l=1}^{N}{}'(u_k u_l|\frac{1}{\rho_{kl}}|u_k u_l)_{kl}. \tag{8.46}$$

Note that in this expression the particle index and state index coincide, a direct consequence of Eq. (8.44). Since the outcome of the integrals only depends on the orbitals involved we can drop the particle indices and write the expression in the form

$$\varepsilon(u_1, \cdots u_N) = \sum_{\kappa=1}^{N}\langle u_\kappa|h_0|u_\kappa\rangle + \tfrac{1}{2}\sum_{\kappa,\nu=1}^{N}{}'(u_\kappa u_\nu|\frac{1}{\rho_{12}}|u_\kappa u_\nu). \tag{8.47}$$

Applying the variational procedure of Appendix I.1.3 we require that the energy be *stationary* under arbitrary *norm-conserving* variations of any of the orbitals u_κ while keeping the other orbitals fixed [102, 43]. For this purpose we consider the energy $\varepsilon(u_1, \cdots u_N)$ as a functional of the electronic orbitals. For the orbital u_κ this functional is

$$H_\kappa(u_1, \cdots, u_N) = \langle u_\kappa|h_0|u_\kappa\rangle + \tfrac{1}{2}\sum_{\nu=1}^{N}{}'\left[(u_\kappa u_\nu|\frac{1}{\rho_{12}}|u_\kappa u_\nu) + (u_\nu u_\kappa|\frac{1}{\rho_{12}}|u_\nu u_\kappa)\right], \tag{8.48}$$

where the prime indicates $\nu \neq \kappa$. Using the equality $(u_\kappa u_\nu|1/\rho_{12}|u_\kappa u_\nu) = (u_\nu u_\kappa|1/\rho_{12}|u_\nu u_\kappa)$ the functional becomes

$$H_\kappa(u_1, \cdots, u_N) = \langle u_\kappa|h_0|u_\kappa\rangle + \sum_{\nu=1}^{N}{}'(u_\kappa u_\nu|\frac{1}{\rho_{12}}|u_\kappa u_\nu), \tag{8.49}$$

which represents the sum of the unscreened *one-electron* contribution plus the *pair* contribution of the Coulomb interaction between the u_κ electron and all other electrons. The total energy $\varepsilon(u_1, \cdots u_N)$ is stationary if the functionals $H_\kappa(u_1, \cdots, u_N)$ are simultaneously stationary under variation of the u_κ. The *optimized* values are denoted by

$$\varepsilon = \varepsilon(u_1, \cdots, u_N)|_{\text{opt}} \quad \text{and} \quad \varepsilon_\kappa = H_\kappa(u_1, \cdots, u_N)|_{\text{opt}}. \tag{8.50}$$

Importantly, the total energy is *not* simply sum of the $H_\kappa(u_1, \cdots, u_N)|_{\text{opt}}$,

$$\varepsilon \neq \sum_{\kappa=1}^{N} \varepsilon_\kappa = \sum_{\kappa=1}^{N} \langle u_\kappa|h_0|u_\kappa\rangle + \sum_{\kappa,\nu=1}^{N}{}'(u_\kappa u_\nu|\frac{1}{\rho_{12}}|u_\kappa u_\nu), \tag{8.51}$$

because this would amount to double counting of the interactions. The proper expression is found by subtracting the interaction energy,

$$\varepsilon = \sum_{\kappa=1}^{N} \varepsilon_\kappa - \tfrac{1}{2}\sum_{\mu,\nu=1}^{N}{}'(u_\mu u_\nu|\frac{1}{\rho_{12}}|u_\mu u_\nu). \tag{8.52}$$

This expression also follows from a comparison of Eqs. (8.47) and (8.49).

Adopting the notation of Eq. (7.46a) we can write Eq. (8.52) in the form

$$\varepsilon = \sum_{\kappa=1}^{N} \varepsilon_\kappa - \tfrac{1}{2}\sum_{\mu,\nu=1}^{N}{}'\mathcal{J}(u_\kappa, u_\nu) \tag{8.53}$$

and the optimized form of Eq. (8.49) becomes

$$\varepsilon_\kappa = \langle u_\kappa|h_0|u_\kappa\rangle + \sum_{\nu=1}^{N}{}'\mathcal{J}(u_\kappa, u_\nu). \tag{8.54}$$

Substituting this expression into Eq. (8.53) we regain Eq. (8.47) but now in the form

$$\varepsilon = \sum_{\kappa=1}^{N} \langle u_\kappa|h_0|u_\kappa\rangle + \tfrac{1}{2}\sum_{\kappa,\nu=1}^{N}{}'\mathcal{J}(u_\kappa, u_\nu). \tag{8.55}$$

At this point we could use the procedure of Section 7.4 to evaluate the integrals $\mathcal{J}(u_\kappa, u_\nu)$ using hydrogenic wavefunctions and even obtain analytic expressions. However, there is no reason why hydrogenic orbitals would be the optimal choice in many-electron atoms. On the contrary. Therefore, we proceed with the derivation of the Hartree equations. First we write $H_\kappa(u_1, \cdots, u_N)$ as the expectation value of the one-electron Hamiltonian h_κ for an electron in the state $|u_\kappa\rangle$,

$$H_\kappa(u_1, \cdots, u_N) = \langle u_\kappa|h_\kappa|u_\kappa\rangle, \tag{8.56}$$

where

$$h_\kappa = -\tfrac{1}{2}\boldsymbol{\nabla}^2 - \frac{Z}{\rho} + J_\kappa(\rho). \tag{8.57}$$

Here $J_\kappa(\rho)$ represents the potential energy of screening at position ρ approximated by an average of the Coulomb energy over the orbitals of all *other* electrons (i.e., skipping the one in the orbital κ),

$$J_\kappa(\rho_1) = \sum_{\nu=1}^{N}{}' \langle u_\nu | \frac{1}{\rho_{12}} | u_\nu \rangle. \tag{8.58}$$

This is a generalization of the screening function (7.14) derived for the screening of one s electron by the other s electron in helium. The average amounts to a *local density approximation* in which the effects of *correlations* in the relative motion of the electrons are neglected. In view of this average the $U_\kappa(\rho)$ are called a *mean fields* or *effective fields.*

$$\langle u_\kappa | J_\kappa | u_\kappa \rangle = \sum_{\nu=1}^{N}{}' \mathcal{J}(u_\kappa, u_\nu). \tag{8.59}$$

We are now prepared to determine the mean-field energy for the ground state with the aid of the variational principle. The lagrangian for the variation of H_κ under the constraint $\langle u_\kappa | u_\kappa \rangle = 1$ is given by

$$\mathcal{L}_\kappa(u_1, \cdots, u_N, \lambda_\kappa) = \langle u_\kappa | h_\kappa | u_\kappa \rangle + \lambda_\kappa \left[\langle u_\kappa | u_\kappa \rangle - 1 \right], \tag{8.60}$$

where λ_κ is the Lagrange multiplier. Note that in this lagrangian the orthogonality of the orbitals is *not* enforced by a constraint. As discussed in Appendix I.1.3, for hermitian operators it suffices to minimize the lagrangian (8.60) through variation of $\langle u_\kappa |$,

$$\delta \mathcal{L}_\kappa = \langle \delta u_\kappa | h_\kappa | u_\kappa \rangle + \lambda_\kappa \langle \delta u_\kappa | u_\kappa \rangle = 0. \tag{8.61}$$

With this procedure the orbital u_κ is found as the stationary solution corresponding to the eigenvalue $\varepsilon_\kappa = -\lambda_\kappa$ of the effective single-electron Schrödinger equation

$$h_\kappa | u_\kappa \rangle = \varepsilon_\kappa | u_\kappa \rangle. \tag{8.62}$$

This expression represents a set of N differential equations known as the *Hartree equations*, one for each orbital u_κ, and coupled through the mean field potentials. This result is quite intuitive. The Schrödinger equation for electronic motion in the bare nuclear field (as used for hydrogenic atoms) is replaced by a set of Hartree equation for electrons moving in the *mean field* of the nucleus screened by the other electrons,

$$\left[-\tfrac{1}{2} \boldsymbol{\nabla}^2 - \frac{Z}{\rho} + J_\kappa(\rho) \right] u_\kappa(\boldsymbol{\rho}) = \varepsilon_\kappa u_\kappa(\boldsymbol{\rho}). \tag{8.63}$$

These equations have to be solved iteratively by numerical integration until self-consistency is reached between the orbitals u_κ and the corresponding screening functions 8.58. The energy ε_κ can be interpreted as the energy (in atomic units) required for the instant removal of an electron in the orbital $|u_\kappa\rangle$. In experiments the observed ionization energy will generally be different because the removal of one electron will also affect the screening of the other electrons. We return to the interpretation of ε_κ in Section 10.2.4 when discussing *Koopmans' theorem* in the context of the Hartree-Fock equations.

Example: Because the central field Hamiltonian is invariant under rotations, n, l and m_l remain good quantum numbers and, like in the case of hydrogen, the orbital wavefunctions must be of the general form

$$\psi_{nlm}(\boldsymbol{\rho}) = P_{nl}(\rho) Y_l^m(\hat{\mathbf{r}}). \tag{8.64}$$

The Hartree wavefunctions $P_{nl}(\rho)$ satisfy the radial wave equation

$$\left[\frac{1}{2} \left(-\frac{d^2}{d\rho^2} - \frac{2}{\rho} \frac{d}{d\rho} + \frac{l(l+1)}{\rho^2} \right) - \frac{Z}{\rho} + J_{nl}(\rho) \right] P_{nl}(\rho) = \varepsilon_{nl} P_{nl}(\rho) \tag{8.65}$$

and differ of course from the hydrogenic one because the screening distorts the electrostatic potential into a non-Coulomb form. The set of N equations (8.62) are called the *Hartree equations*, one for each electron. They have to be solved iteratively using numerical integration. Starting from the hydrogenic wavefunctions $\tilde{R}_{nl}(\rho)$ of the electron configuration we obtain an educated guess for the potential energy of screening $U_{\mathrm{scr}}(\rho)$ of the electron under consideration in the screened field of the nucleus. Then we can solve the Hartree equations and obtain new radial wavefunctions $P_{nl}(\rho)$ for the electrons and recalculate the screening integral. This procedure is repeated until self consistency is reached.

The Hartree method has been used a lot in the past in spite of the neglect of exchange. The practical importance of the method has essentially vanished because the relative simplicity of the Hartree wavefunctions is no longer important from the computational point of view. Without much additional effort one can replace the Hartree wavefunctions by Hartree-Fock wavefunctions, which properly take into account the required antisymmetry of the many-electron wavefunction under interchange of two electrons. We return to the many-electron wavefunctions in Chapter 9.

8.5 Quantum defects for alkali-like atoms

For another example of a central field approximation we consider many-electron atoms with a single outer electron such as the alkali atoms or singly charged ions of "two-electron" atoms, like Ba$^+$. Also all atoms with a single highly excited electron, called *Rydberg atoms*, fall in this class. In these cases it still is possible to use the formalism developed for hydrogen because at large distances from the core the outer electron will observe a core charge equal to the elementary charge, just like in the case of hydrogen. Obviously, within the cloud of core electrons screening of the nuclear charge must be taken into account. For this purpose we introduce an effective nuclear charge $Z_{\mathrm{eff}}(\rho)$, which is a function of the distance to the nucleus. The radial wave equation can be written in the form (8.65) and, introducing the reduced radial wavefunction $\tilde{\chi}_{nl}(\rho) = \rho\tilde{R}_{nl}(\rho)$, also in the form of a 1D-Schrödinger equation

$$\tilde{\chi}_{nl}'' + 2\left[Z_{\mathrm{eff}}(\rho)/\rho - l(l+1)/2\rho^2 - \varepsilon_{nl}\right]\tilde{\chi}_{nl} = 0. \tag{8.66}$$

In view of the limiting behavior of the effective charge, $\lim_{\rho\to\infty} Z_{\mathrm{eff}}(\rho) = 1$ and $\lim_{\rho\to 0} Z_{\mathrm{eff}}(\rho) = Z$, we expect the same limiting expressions for the radial wave equation as in the case of hydrogenic atoms. For $\rho \to \infty$ the Eq. (8.66) may be approximated by

$$\tilde{\chi}_{nl}'' - 2\varepsilon_{nl}\tilde{\chi}_{nl} = 0, \tag{8.67}$$

with solution $\tilde{\chi}_{nl}(\rho) \sim e^{-\rho\sqrt{2\varepsilon}}$. For $\rho \to 0$ the limiting expression is

$$\tilde{\chi}_{nl}'' - \left[l(l+1)/\rho^2\right]\tilde{\chi}_{nl} = 0, \tag{8.68}$$

with solution $\tilde{\chi}_{nl}(\rho) \sim \rho^{l+1}e^{-\rho\sqrt{2\varepsilon}}$. Thus, like in the case of hydrogen, the wavefunction is of the form

$$\tilde{\chi}_{nl}(\rho) = \rho^{l+1}e^{-\rho\sqrt{2\varepsilon_{nl}}}\tilde{w}_{nl}(\rho), \tag{8.69}$$

where $\tilde{w}_{nl}(\rho)$ is some crossover function between the expression of the wavefunction at short range and at large range. The remaining difficulty is that the binding energies ε_{nl} are not known. At this point we cannot calculate these values because the electrostatic potential of the central field is not known.

Interestingly, Bates and Damgaard found a semi-empirical approach by which we can bootstrap ourselves to an approximate solution in which detailed knowledge of the central field is not necessary [9]. Rather than calculating the energy levels the experimental values are used. As long as the levels are only shifted slightly, the number of nodes in the radial wavefunction remains unaffected; i.e., $n' = n - l - 1$ remains unchanged.

Table 8.1: Transition dipole moments and transition strengths for hydrogen, metastable helium and the alkali atoms.

El.	Transition $\lvert g\rangle \to \lvert e\rangle$	n_s^*	n_p^*	D_{eg}(a.u.)	D_{eg}^2(a.u.)
H	$1s \to 2p$	1.000	2.000	0.745	0.555
He*	$2s \to 2p$	1.689	1.938	2.59	6.452
Li	$2s \to 2p$	1.589	1.959	2.40	5.532
Na	$3s \to 3p$	1.627	2.117	2.29	5.978
K	$4s \to 4p$	1.770	2.235	2.71	8.077
Rb	$5s \to 5p$	1.805	2.293	2.77	8.509
Cs	$6s \to 6p$	1.869	2.362	2.95	9.567

To represent a proper set of eigenfunctions the wavefunctions must be orthonormal and this is the case for Eq. (2.37). Bates and Damgaard found that a normalized wave function with the correct asymptotic behavior for $\rho \to \infty$ is obtained by using hydrogenic wavefunctions (2.37) in which the principal quantum number n is replaced by n^* and the angular momentum quantum number l by l^*,

$$\tilde{R}_{n^*,l^*}(\rho) = \mathcal{N}^{-1/2}(2Z/n^*)^{l^*+3/2}\rho^{l^*}e^{-Z\rho/n_i^*}L_{n^*-l^*-1}^{2l^*+1}(2Z\rho/n^*)\,, \tag{8.70}$$

with normalization constant

$$\mathcal{N} = \frac{2n^*\Gamma(n^*+l^*+1)}{\Gamma(n^*-l^*)}. \tag{8.71}$$

Note that $n^* - l^* = n - l$. Inspecting the solution Eq. (8.70), we find that the wave function remained normalized because the boundary condition near the origin was properly adjusted, $\tilde{\chi}_l(\rho) \simeq \rho^{l+1-\delta_l}$ for $r \to 0$. This means that close the origin the wavefunctions are inaccurate but for many applications this is not important. For instance, for the valence electron in alkali atoms the radial integrals with $\nu \geq 1$ are given to good approximation by

$$\langle \rho^\nu \rangle = \int \rho^{2+\nu}[\tilde{R}_{n^*l^*}(\rho)]^2 d\rho. \tag{8.72}$$

Although this integral cannot be evaluated analytically like in the case of hydrogen straightforward numerical calculation is possible. Importantly, wavefunctions of the type Eq. (8.70) offer a good approximation to calculate optical transition strength for the alkali atoms on the basis of the quantum defects tabulated above.

8.5.1 Radial averages

In the case of the alkali atoms the radial integrals cannot be evaluated analytically because the quantum defects give rise to non-integer values of the quantum numbers,

$$\langle \rho^\nu \rangle = \int \rho^{2+\nu}[\tilde{R}_{n^*l^*}(\rho)]^2 d\rho. \tag{8.73}$$

However, the eigenfunctions given in Section 2.4 still allow straightforward numerical evaluation with *Mathematica*, at least as long as the principal quantum numbers are not too large.

For s-p transitions we have with Eq. (8.70)

$$\tilde{R}_{n_i0}(\rho) = \mathcal{N}_i^{-1/2}(2Z/n^*)^{-\delta_s+3/2}\rho^{-\delta_s}e^{-\rho/n_i^*}L_{n_i^*+\delta_s-1}^{1-2\delta_s}(2\rho/n_i^*) \tag{8.74}$$

$$\tilde{R}_{n_f1}(\rho) = \mathcal{N}_f^{-1/2}(2Z/n_f^*)^{-\delta_p+5/2}\rho^{1-\delta_p}e^{-\rho/n_f^*}L_{n_f^*+\delta_p}^{3-2\delta_p}(2\rho/n_f^*), \tag{8.75}$$

where the normalizations are given by Eq. (8.71). In Table 8.1 we give the results for the first optically allowed transitions (*s*-*p* transitions) of some atomic systems from their ground state.

9

Many-electron wavefunctions

To introduce the subject of many-electron wavefunctions, we first recall the consequences of the indistinguishability of identical particles in quantum mechanics. Two particles are called identical if there is no physical way to establish whether or not the particles have been exchanged. This condition is satisfied for particles with identical internal structure because, in quantum mechanics, it is fundamentally impossible to label a particle by tracking its motion along an orbit. The latter is only possible in classical mechanics as it requires the simultaneous determination of position and momentum. The state of the pair is represented by the pair wavefunction

$$\psi\left(\mathbf{r}_1, \sigma_1; \mathbf{r}_2, \sigma_2\right), \tag{9.1}$$

where $\mathbf{r}_1$ and $\mathbf{r}_2$ are the *position coordinates* and σ_1 and σ_2 the *spin coordinates*, respectively (see Appendix F.1.4). The squared modulus of the wavefunction,

$$|\psi\left(\mathbf{r}_1, \sigma_1; \mathbf{r}_2, \sigma_2\right)|^2, \tag{9.2}$$

corresponds to the probability of observing one particle (say particle 1) at position $\mathbf{r}_1$ in spin state σ_1 with the other particle (say particle 2) at position $\mathbf{r}_2$ in spin state σ_2. With this procedure we labeled the particles by the position of observation. It does *not* mean that we observe a labeled particle. The latter is only possible for particles with a difference in internal structure (the "label"). Next we allow for interchange of particles before doing the measurement. Formally this is realized by introducing the *exchange operator* P_{12},

$$P_{12}\psi\left(\mathbf{r}_1, \sigma_1; \mathbf{r}_2, \sigma_2\right) \equiv \psi\left(\mathbf{r}_2, \sigma_2; \mathbf{r}_1, \sigma_1\right). \tag{9.3}$$

As "tracking" is fundamentally impossible in quantum mechanics, we have no physical means to establish whether or not two identical particles have been exchanged. This means that the probability to observe particle 2 at position $\mathbf{r}_1$ in spin state σ_1 with particle 1 at position $\mathbf{r}_2$ in spin state σ_2 is equal to that of observing particle 1 at position $\mathbf{r}_1$ in spin state σ_1 with particle 2 at position $\mathbf{r}_2$ in spin state σ_2 :

$$|\psi\left(\mathbf{r}_1, \sigma_1; \mathbf{r}_2, \sigma_2\right)|^2 = |\psi\left(\mathbf{r}_2, \sigma_2; \mathbf{r}_1, \sigma_1\right)|^2. \tag{9.4}$$

This shows that P_{12} has to be *norm-conserving*,

$$\langle\psi|P_{12}^{\dagger}P_{12}|\psi\rangle = \langle\psi|\psi\rangle = 1, \tag{9.5}$$

but also that the particle indices, 1 and 2, have no physical significance.

Let us have a closer look at the exchange operator. Because P_{12} is norm-conserving, we have

$$P_{12}^{\dagger}P_{12} = \mathbb{1} \tag{9.6}$$

and

$$P_{12}|\psi\rangle = e^{-i\theta}|\psi\rangle. \tag{9.7}$$

Furthermore, exchanging the particles twice must leave the pair state unchanged. Rewriting the phase angle in the form $\theta = n\,\pi + \varphi$ (which can be done without loss of generality) we find from Eq. (9.7)

$$P_{12}^2|\psi\rangle = e^{-i2\varphi}|\psi\rangle. \tag{9.8}$$

So the question arises for what value of φ the pair state is invariant under all possible ways to exchange the particles twice. For 3D systems (and in the absence of topological excitations)[1] this is the case only for $\varphi = 0$; i.e., for

$$P_{12}^2 = \mathbb{1}. \tag{9.9}$$

Writing $P_{12}^{\dagger} = P_{12}^{\dagger}P_{12}^2 = P_{12}$ we see that P_{12} is *hermitian*; i.e., the eigenvalues of P_{12} are real an take the values ±1. In view of the definition (9.3) these eigenvalues correspond to pair wavefunctions which are either *symmetric* (+1) or *antisymmetric* (−1) under exchange of the particles.

As, by definition, the pair Hamiltonian $\mathcal{H}$ is invariant under exchange of identical particles, P_{12} commutes with $\mathcal{H}$, which implies that P_{12} and $\mathcal{H}$ share a complete set of eigenstates. Therefore, the eigenstates of P_{12} span the full Hilbert space of the pair and P_{12} is not only hermitian but also an *observable.* In nature, particles of a given species are always found in states showing the same symmetry under exchange, corresponding to *only one* of the eigenvalues of P_{12}. Apparently, for *identical* particles the pair wavefunction has to be an *eigenfunction* of the exchange operator; i.e., the exchange symmetry is conserved in time. If the wavefunction is symmetric under exchange of two particles the particles are called *bosons*, if antisymmetric they are called *fermions.* The division of particles into bosons and fermions points to a rigorously enforced underlying principle, which is found in relativistic quantum field theory in the form of the *spin-statistics theorem.* Discussion of this fundamental theorem falls outside the scope of this course. We accept it as a postulate in which bosons always carry *integral* total *spin* and fermions *half-integral* total spin. Taking into account the spin-statistics theorem, the action of the exchange operator is summarized by the expression

$$P_{12}\psi\left(\mathbf{r}_1,\sigma_1;\mathbf{r}_2,\sigma_2\right) = e^{-i2\pi s}\psi\left(\mathbf{r}_1,\sigma_1;\mathbf{r}_2,\sigma_2\right), \tag{9.10}$$

where s is the (integral or half-integral) spin of the particle.

Problem 9.1. Show that any pair wavefunction can be written as the sum of a part symmetric and a part antisymmetric under exchange of the particles of the pair.

Solution. For any pair state we have $|\psi\rangle = \frac{1}{2}\left(\mathbb{1} + P_{12}\right)|\psi\rangle + \frac{1}{2}(\mathbb{1} - \mathcal{P})\,|\psi\rangle$, where P_{12} is the exchange operator, $P_{12}^2 = \mathbb{1}$. The first term is symmetric, $P_{12}\left(\mathbb{1} + P_{12}\right)|\psi\rangle = \left(P_{12} + P_{12}^2\right)|\psi\rangle = \left(\mathbb{1} + P_{12}\right)|\psi\rangle$, and the second term is antisymmetric, $P_{12}\left(\mathbb{1} - P_{12}\right)|\psi\rangle = \left(P_{12} - P_{12}^2\right)|\psi\rangle = -\left(\mathbb{1} - P_{12}\right)|\psi\rangle$. □

9.1 Quantum correlations, Pauli principle and Slater determinants

Let us specialize to the case of two $s = \frac{1}{2}$ fermions in the pair state $\psi\left(\mathbf{r}_1,\sigma_1;\mathbf{r}_2,\sigma_2\right)$. Eq. (9.10) shows that the pair state must be antisymmetric under exchange of the particles,

$$\psi\left(\mathbf{r}_2,\sigma_2;\mathbf{r}_1,\sigma_1\right) = -\psi\left(\mathbf{r}_1,\sigma_1;\mathbf{r}_2,\sigma_2\right). \tag{9.11}$$

For two fermions in the same spin state ($\sigma_2 = \sigma_1 = \sigma$) and at the same position ($\mathbf{r}_1 = \mathbf{r}_2 = \mathbf{r}$) this condition becomes $\psi\left(\mathbf{r},\sigma;\mathbf{r},\sigma\right) = -\psi\left(\mathbf{r},\sigma;\mathbf{r},\sigma\right)$. So, it follows that these fermions have zero

---

[1] The general case was analyzed by Jon Leinaas and Jan Myrheim in 1977 [71]. In 2D (or 3D in the presence of vorticity), the phase angle θ corresponds to a rotation angle, with $\theta_1 = n\,\pi + \varphi$ being equivalent to $\theta_2 = -(n\,\pi - \varphi)$. This implies that exchange with $\theta_1 + \theta_2 = 2\varphi \neq 0$ is a physical option. It gives rise to quantum statistics with its own type of identical particle called anyon (with fractional spin defined by $\theta = 2\pi s$) [123].

probability to be at the same position; i.e., *they avoid each other.* Apparently, for two fermions in the same spin state the motion is correlated as a result of the symmetry conditions. These kinematic correlations are purely quantum mechanical in origin and clearly *not* the result of potential forces (e.g., electrostatic) between the particles. The correlations affect the distribution over position and momentum with major consequences for statistical treatments of quantum many-body systems (in our case Fermi-Dirac statistics). In particular, the condition that two fermions in the same spin state cannot be at the same position excludes the possibility that they are in the same state. This is known as the *Pauli exclusion principle.*

9.1.1 Antisymmetric pair states for electrons

As an important example of $s = \frac{1}{2}$ fermions we consider the case of two electrons. With one electron in state $|\alpha_1\rangle$ and the other in state $|\alpha_2\rangle$, the standard method to form a pair state is by constructing the product state

$$|\alpha_1, \alpha_2) \equiv |\alpha_1\rangle_1 \otimes |\alpha_2\rangle_2, \tag{9.12}$$

where the ket $|\alpha_\kappa\rangle_i$ represents electron i in state $|\alpha_\kappa\rangle$. However, this state state does not qualify as a proper two-electron state because it is not antisymmetric under exchange as is required for fermionic particles. The simplest pair state with the proper symmetry has the form of a 2×2 determinant,[1]

$$|\alpha_1, \alpha_2\rangle = \sqrt{\tfrac{1}{2}}\left[|\alpha_1, \alpha_2) - |\alpha_2, \alpha_1)\right] = \sqrt{\tfrac{1}{2}}\begin{vmatrix} |\alpha_1\rangle_1 & |\alpha_2\rangle_1 \\ |\alpha_1\rangle_2 & |\alpha_2\rangle_2 \end{vmatrix}. \tag{9.13}$$

By construction determinants are antisymmetric under exchange of the rows (particle index) or, equivalently, the columns (state index),

$$P_{12}|\alpha_1, \alpha_2\rangle = -|\alpha_2, \alpha_1\rangle. \tag{9.14}$$

For equal states, $|\alpha_1\rangle = |\alpha_2\rangle$, the determinant vanishes in accordance with the Pauli principle.

Now we apply this symmetrization procedure to *spinorbitals*, the single electron eigenstates. These are defined by specifying both the orbital u and the spin state ($|\uparrow\rangle$ or $|\downarrow\rangle$ of the electron. In search for a compact notation we decorate the orbital with a dot for *spin-up* and with a bar for *spin-down*,

$$|\dot{u}\rangle \equiv |u\uparrow\rangle \equiv |u\rangle \otimes |\uparrow\rangle \qquad \text{and} \qquad |\overline{u}\rangle \equiv |u\downarrow\rangle \equiv |u\rangle \otimes |\downarrow\rangle\,. \tag{9.15}$$

In this notation any properly symmetrized state of two electrons in the orbitals u and v can be written as a linear combination of an orthonormal set of four 2×2 determinants,

$$|\dot{u}, \dot{v}\rangle\,, |\dot{u}, \overline{v}\rangle\,, |\overline{u}, \dot{v}\rangle\,, |\overline{u}, \overline{v}\rangle\,. \tag{9.16}$$

Because the sign of the determinants depends on the ordering of the rows and columns we fix the phase by convention. We shall use alphabetic ordering of the orbitals (u precedes v) followed by *up* precedes *down.*

9.1.1.1 Coulomb repulsion integrals for electron pairs

The determinants of the basis (9.16) are properly symmetrized but they are not the singlet and triplet eigenstates obtained in Section 7.3 for the Coulomb repulsion energy in the helium atom. The reason is that the 2×2 determinants are eigenstates of the exchange operator P_{12} but not of the atomic hamiltonian of two electrons moving in the central potential $-Z(\rho)/\rho$,

$$\mathcal{H} = \sum_{i=1}^{2}\left[-\tfrac{1}{2}\boldsymbol{\nabla}_i^2 - Z(\rho_i)/\rho_i\right] + \rho_{12}^{-1}. \tag{9.17}$$

---

[1] Note the use of curved brackets for product states and angled brackets for symmetrized states.

As all electrons are identical and the Coulomb repulsion only depends of the interparticle distance, $\mathcal{H}$ is manifestly invariant under exchange of the electrons. Hence, P_{12} commutes with $\mathcal{H}$ and the operators P_{12} and $\mathcal{H}$ must share a complete set of eigenstates. This means that, like the states (9.16), also the energy eigenstates can be written in a form antisymmetric under exchange of the electrons. The difficulty is that, in general, this cannot be done using a single 2×2 determinant. In search for the proper linear combinations we write the perturbation $\mathcal{H}' = \rho_{12}^{-1}$ in the basis (9.16),

$$\mathcal{H}' = \begin{pmatrix} \mathcal{J}-\mathcal{K} & & & \\ & \mathcal{J} & \mathcal{K} & \\ & \mathcal{K} & \mathcal{J} & \\ & & & \mathcal{J}-\mathcal{K} \end{pmatrix}. \tag{9.18}$$

Let us verify this for the matrix elements of the *spin-up* stretched state $|\dot{u},\dot{v}\rangle = |u,v\rangle\,|{\upuparrows})$. Expanding the determinant, $|\dot{u},\dot{v}\rangle = \frac{1}{\sqrt{2}}\left[|uv) - |vu)\right]|{\upuparrows})$, we obtain for the diagonal contribution

$$\langle\dot{u},\dot{v}|\,\rho_{12}^{-1}\,|\dot{u},\dot{v}\rangle = \tfrac{1}{2}\left[(uv|\rho_{12}^{-1}|uv) - (uv|\rho_{12}^{-1}|vu) - (vu|\rho_{12}^{-1}|uv) + (vu|\rho_{12}^{-1}|vu)\right] = \mathcal{J}-\mathcal{K}, \tag{9.19}$$

where $\mathcal{J}$ and $\mathcal{K}$ are the direct and exchange integrals defined in Eqs. (7.46a) and (7.46b), respectively. The off-diagonal contributions of $|\dot{u},\dot{v}\rangle$ are all zero because because at least one of the electrons is in a down-spin state. The matrix elements of the non-stretched states are calculated in Problems 9.2 and 9.3. Diagonalizing the Hamiltonian we obtain the singlet and triplet eigenvalues

$$E_{0,0}(u,v) = \mathcal{J}(u,v) + \mathcal{K}(u,v) = \Delta E_+ \tag{9.20a}$$

$$\left.\begin{array}{r} E_{1,1}(u,v) \\ E_{1,0}(u,v) \\ E_{1,-1}(u,v) \end{array}\right\} = \mathcal{J}(u,v) - \mathcal{K}(u,v) = \Delta E_-. \tag{9.20b}$$

These energies correspond to the Coulomb repulsion shift with respect to the energy of two noninteracting electrons moving in the central potential $-Z(\rho)/\rho$. These shifts were also obtained (for $Z(\rho) \equiv 2$) in Section 7.3. The corresponding eigenstates are (in standard ordering)

$$\begin{array}{rl} |\psi_{u,v}^{-};1,1\rangle = |\dot{u},\dot{v}\rangle & \\ |\psi_{u,v}^{-};1,0\rangle = \frac{1}{\sqrt{2}}\left[|\dot{u},\overline{v}\rangle + |\overline{u},\dot{v}\rangle\right] & \qquad |\psi_{u,v}^{+};0,0\rangle = \frac{1}{\sqrt{2}}\left[|\dot{u},\overline{v}\rangle - |\overline{u},\dot{v}\rangle\right]. \\ |\psi_{u,v}^{-};1,-1\rangle = |\overline{u},\overline{v}\rangle & \end{array} \tag{9.21}$$

Problem 9.2. Show that for the matrix elements of the type $\langle\dot{u}\overline{v}|\rho_{12}^{-1}|\dot{u}\overline{v}\rangle$ the *exchange* terms vanish,

$$\langle\dot{u}\overline{v}|\rho_{12}^{-1}|\dot{u}\overline{v}\rangle = (uv|\rho_{12}^{-1}|uv) = \mathcal{J}.$$

Solution. Using the determinant $|\dot{u},\overline{v}\rangle = \frac{1}{\sqrt{2}}\left[|\dot{u}\overline{v}) - |\overline{v}\dot{u})\right]$ the matrix element becomes

$$\begin{aligned} \langle\dot{u}\overline{v}|\rho_{12}^{-1}|\dot{u}\overline{v}\rangle &= \tfrac{1}{2}\left[(\dot{u}\overline{v}|\rho_{12}^{-1}|\dot{u}\overline{v}) - (\dot{u}\overline{v}|\rho_{12}^{-1}|\overline{v}\dot{u}) - (\overline{v}\dot{u}|\rho_{12}^{-1}|\dot{u}\overline{v}) + (\overline{v}\dot{u}|\rho_{12}^{-1}|\overline{v}\dot{u})\right] \\ &= \tfrac{1}{2}\left[(uv|\rho_{12}^{-1}|uv) + (vu|\rho_{12}^{-1}|vu)\right] = \mathcal{J}, \end{aligned}$$

where $\mathcal{J}$ is the direct integral (7.46a). Note that $(\dot{u}\overline{v}|\rho_{12}^{-1}|\overline{v}\dot{u}) = ({\updownarrows}\,|{\downuparrows})\,\mathcal{K} = 0$ and $(\overline{v}\dot{u}|\rho_{12}^{-1}|\dot{u}\overline{v}) = ({\downuparrows}\,|{\updownarrows})\,\mathcal{K} = 0$, where $\mathcal{K}$ is the exchange integral (7.46b). □

Problem 9.3. Show that for the matrix elements of the type $\langle\dot{u},\overline{v}|\rho_{12}^{-1}|\dot{v},\overline{u}\rangle$ the *direct* terms vanish,

$$\langle\dot{u}\overline{v}|\rho_{12}^{-1}|\dot{v}\overline{u}\rangle = (uv|\rho_{12}^{-1}|vu) = \mathcal{K}.$$

Solution. Using the determinants $|\dot{u}\overline{v}\rangle = \frac{1}{\sqrt{2}}\left[|\dot{u}\overline{v}) - |\overline{v}\dot{u})\right]$ and $|\dot{v}\overline{u}\rangle = \frac{1}{\sqrt{2}}\left[|\dot{v}\overline{u}) - |\overline{u}\dot{v})\right]$ the matrix element becomes

$$\begin{aligned} \langle\dot{u}\overline{v}|\rho_{12}^{-1}|\dot{u}\overline{v}\rangle &= \tfrac{1}{2}\left[(\dot{u}\overline{v}|\rho_{12}^{-1}|\dot{v}\overline{u}) - (\dot{u}\overline{v}|\rho_{12}^{-1}|\overline{u}\dot{v}) - (\overline{v}\dot{u}|\rho_{12}^{-1}|\dot{v},\overline{u}) + (\overline{v}\dot{u}|\rho_{12}^{-1}|\overline{u}\dot{v})\right] \\ &= \tfrac{1}{2}\left[(uv|\rho_{12}^{-1}|vu) + (vu|\rho_{12}^{-1}|uv)\right] = \mathcal{K}, \end{aligned}$$

where $\mathcal{K}$ is the exchange integral (7.46b). Note further that $(\dot{u}\overline{v}|\rho_{12}^{-1}|\overline{u},\dot{v}) = ({\updownarrows}\,|{\downuparrows})\,\mathcal{J} = 0$ and $(\overline{v}\dot{u}|\rho_{12}^{-1}|\dot{v},\overline{u}) = ({\downuparrows}\,|{\updownarrows})\,\mathcal{J} = 0$ is the direct integral (7.46a). □

9.1.2 Spinorbitals and Slater determinants

An important tool to deal with many-electron systems is the *Slater determinant.* Its discovery by John Slater marks a true milestone in many-body physics [101]. The Slater determinant is the simplest generalization of the product wavefunction with the proper symmetry under interchange of any two electrons and consistent the Pauli principle. For N fermions the Slater determinant is written as

$$\psi_\alpha(\mathbf{r}_1,\sigma_1;\cdots;\mathbf{r}_N,\sigma_N)=\sqrt{\frac{1}{N!}}\begin{vmatrix}\varphi_{\alpha_1}(\mathbf{r}_1,\sigma_1) & \cdots & \varphi_{\alpha_N}(\mathbf{r}_1,\sigma_1)\\ \vdots & \dots & \vdots\\ \varphi_{\alpha_1}(\mathbf{r}_N,\sigma_N) & \cdots & \varphi_{\alpha_N}(\mathbf{r}_N,\sigma_N)\end{vmatrix}. \tag{9.22}$$

Indeed, the property of determinants to vanish when two columns or two rows are equal assures that the wavefunction vanishes when two electrons are in the same state α or share the same (position and spin) coordinates $(\mathbf{r}_i,\sigma_i)$, while exchanging two rows or two columns yields the minus sign required for anti-symmetric wavefunctions. In Dirac notation the antisymmetrized form of N fermions in states $\alpha_1,\cdots,\alpha_N$ is given by

$$|\psi_\alpha\rangle\equiv|\alpha_1,\cdots,\alpha_N\rangle\equiv\sqrt{\frac{1}{N!}}\sum_P(-1)^pP|\alpha_1,\cdots\alpha_N), \tag{9.23}$$

where

$$|\alpha_1,\cdots\alpha_N)\equiv|\alpha_1\rangle_1\otimes|\alpha_2\rangle_2\otimes\cdots|\alpha_N\rangle_N\equiv|\psi_\alpha) \tag{9.24}$$

is the N-body ordered product of the single-particle states $|\alpha_\kappa\rangle_i$, where $\kappa\in\{1,\cdots,N\}$ is the *state index* and $i\in\{1,\cdots,N\}$ the *particle index.* The sum runs over all permutations P of the particles, p being the *parity* (number of *transpositions*; i.e., binary interchanges) required to realize the permutation starting from an initial ordering fixed by convention. As the sum runs over all permutations, it makes no difference whether we permute all particles or permute all states of the particles. We choose the permutation operator P *to act on the state index* (κ) and *not on the particle index* (i). With this choice, the interchange of the states of particles 1 and 2 is written as

$$P|\alpha_1,\alpha_2,\cdots\alpha_N)=|\alpha_2,\alpha_1,\cdots\alpha_N)=|\alpha_2\rangle_1\otimes|\alpha_1\rangle_2\otimes\cdots|\alpha_N\rangle_N\,. \tag{9.25}$$

To assure a uniquely defined sign of the Slater determinants we shall adopt the *standard ordering convention* of atomic configurations (see later). The state labeling $\alpha_1,\cdots,\alpha_N$ refers to the *spinorbitals* introduced in Dirac notation in Eqs. (9.15). The spinorbital $\varphi_{u\uparrow}(\mathbf{r}_i,\sigma_i)=\varphi_u(\mathbf{r})\chi_\uparrow(\sigma)$ corresponds to spin-up electron in the motional state $\varphi_u(\mathbf{r})$.

9.1.3 Slater determinants - notations and ordering convention

The rows of the Slater determinant (9.22) differ only in the particle index and the columns only in the state index. Note that is a matter of convention because determinants are invariant under transposition - see property M.21. Whatever our preference and without loss of information, Eq. (9.22) can be written in the short-hand form for the singlets.

$$\psi_\alpha(\mathbf{r}_1,\sigma_1;\cdots;\mathbf{r}_N,\sigma_N)=\det(\alpha_1,\cdots,\alpha_N). \tag{9.26}$$

We will use the Dirac notation, in which the N-electron state $|\psi_\alpha\rangle=|\alpha_1,\cdots,\alpha_N\rangle$ is constructed from one-electron spinorbitals

$$|\alpha_\kappa\rangle=|n^\kappa l^\kappa m_l^\kappa s^\kappa m_s^\kappa\rangle=|u_\kappa\rangle\otimes|s^\kappa m_s^\kappa\rangle, \tag{9.27}$$

where $\kappa\in\{1,\cdots N\}$ is the *state index.* Using the arrow notation for spin, the N-electron state for the spinorbitals $|u\uparrow\rangle$, $|v\uparrow\rangle,\cdots|w\downarrow\rangle$ can be written as (again without loss of information)

$$|\psi_\alpha\rangle=|u\uparrow,v\uparrow,,\cdots,w\downarrow\rangle\equiv|\dot{u},\dot{v},\cdots,\bar{w}\rangle, \tag{9.28}$$

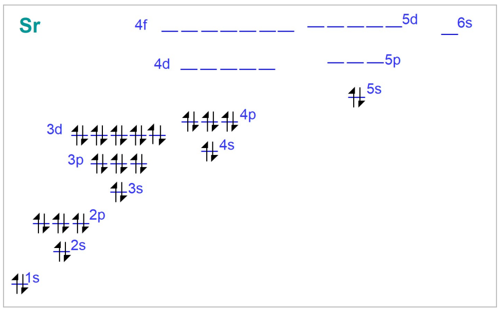

Figure 9.1: Configuration plot for the ground state of Strontium. Note that the arrow notation is a short-hand notation for Slater determinants as explained in the text. The slicing of the arrows has no significance other than offering a compact notation.

where the spin "up" and "down" are indicated by putting a dot or a bar, respectively.

For *equivalent* electrons the states differ in the magnetic quantum numbers,

$$|\alpha_\kappa\rangle = |m_l^\kappa m_s^\kappa\rangle_{nl}. \tag{9.29}$$

For two equivalent s electrons the only possible determinant consistent with the Pauli principle is $|\dot{0},\bar{0}\rangle_{ns^2} \equiv |\upharpoonleft\!\downharpoonright\rangle_{ns^2}$, *e.g.* the ground state of the helium atom is [1]

$$|\psi_{\mathrm{He}}\rangle = |1\dot{s},1\bar{s}\rangle \equiv |\dot{0},\bar{0}\rangle_{1s^2} \equiv |\upharpoonleft\!\downharpoonright\rangle_{1s^2}. \tag{9.30}$$

If we have more than one occupied shell consisting the full state is represented by a joined determinant of order equal to the total number of electrons. Thus we obtain for *beryllium*

$$|\psi_{\mathrm{Be}}\rangle = |1\dot{s},1\bar{s},2\dot{s},2\bar{s}\rangle \equiv |(\dot{0},\bar{0})_{1s^2}(\dot{0},\bar{0})_{2s^2}\rangle = |(\upharpoonleft\!\downharpoonright)_{1s^2}(\upharpoonleft\!\downharpoonright)_{2s^2}\rangle \tag{9.31}$$

and for neon

$$|\psi_{\mathrm{Ne}}\rangle = |1\dot{s},1\bar{s};2\dot{s},2\bar{s};2\dot{p}_1,2\bar{p}_1,2\dot{p}_0,2\bar{p}_0,2\dot{p}_{-1},2\bar{p}_{-1}\rangle \tag{9.32a}$$

$$= |(\dot{0},\bar{0})_{1s^2}(\dot{0},\bar{0})_{2s^2}(\dot{1},\bar{1},\dot{0},\bar{0},-\dot{1},-\bar{1})_{2p^6}\rangle \equiv |(\upharpoonleft\!\downharpoonright)_{1s^2}(\upharpoonleft\!\downharpoonright)_{2s^2}(\upharpoonleft\!\downharpoonright\ \upharpoonleft\!\downharpoonright\ \upharpoonleft\!\downharpoonright)_{2p^6}\rangle. \tag{9.32b}$$

In this way we can write the state of any closed shell configuration in the form of a single Slater determinant: the determinant for which the states satisfy the exclusion principle (i.e., the determinant is non-zero). The example of Strontium is given in Fig. 9.1. Note that the notation with the arrows is the most compact and used in the well-known configuration plots for the various elements. The state notation

$$|2\dot{p}_1,2\bar{p}_1,2\dot{p}_0,2\bar{p}_0,2\dot{p}_{-1},2\bar{p}_{-1}\rangle = |\dot{1},\bar{1},\dot{0},\bar{0},-\dot{1},-\bar{1}\rangle_{2p^6} \tag{9.33}$$

is written conform the *standard ordering convention* for the sign of the determinant: high M_L precedes low M_L and spin up precedes spin down in the *non-permuted* product state $|\dot{1},\bar{1},\dot{0},\bar{0},-\dot{1},-\bar{1})$.

With partially filled shells the situation is more complicated because - in general - they cannot be represented by a single Slater determinant. In the case of two-electron atoms we are dealing with two valence electrons in ns^2, np^2, nd^2 or nf^2 configurations orbiting about an atomic core presenting at large distance from the nucleus a net positive charge $2e$. For the ns^2 configurations one distinguishes *helium-like* atoms and *alkaline-earth-like* atoms.[2] The helium-like atoms were discussed in Chapter 7. Alkaline-earth-like atoms are many-electron atoms consisting of two outer

---

[1] Sliced arrows are used for convenience of notation but have no physical significance.

[2] The *alkaline-earth elements* are to be distinguished from the *alkaline earths*, which are the oxides of the elements. Historically, the notion earths was used for water-insoluble substances that do not burn in fire.

electrons in a ns^2 configuration and a doubly charged central core, thus resembling a two-electron atom like helium. Aside from the alkaline-earth elements (group II) atoms Be, Mg, Ca, Sr and Ba this class also includes the ions of the "three electron atoms" (group III atoms), B^+, Al^+, Ga^+, In^+ and Ti^+. The group IV atoms have configuration np^2 (C, Si, Ge, Sn, Pb). The nd^2 atoms (Ti, Zr, Hf, Rf) are transition metals. For each electron in a nl^2 configuration there are $\nu = 2(2l+1)$ possible states $|nlm_l sm_s\rangle$. For non-equivalent electrons this implies ν^2 possible pair states; i.e., each electron can be paired with an electron in any of the ν possible states. For equivalent electrons we have to exclude the occurrence of two electrons in the same state. This leaves

$$\frac{1}{2}\nu(\nu-1) = \frac{\nu!}{2!(\nu-2)!} = \binom{\nu}{2} \tag{9.34}$$

combinations consistent with the Pauli principle. This procedure is readily generalized to x equivalent electrons in a nl^x configuration. To avoid identical pairs we have to choose x out of ν, which can be done in

$$\binom{\nu}{x} = \frac{\nu!}{x!(\nu-x)!} \tag{9.35}$$

different ways as is well known from combinatorics. Thus, Eq. (9.35) provides the total number of different x-body states consistent with the Pauli principle in nl^x configurations. We return to these cases in Chapter 10.

Problem 9.4. Show that Slater determinants are invariant under unitary transformations.

Solution. To demonstrate this property we write the Slater determinant $|\psi_{\alpha'}\rangle$ in the form

$$|\psi_{\alpha'}\rangle = \sqrt{\frac{1}{N!}} \begin{vmatrix} |\alpha'_1\rangle_1 & \cdots & |\alpha'_1\rangle_N \\ \vdots & \cdots & \vdots \\ |\alpha'_N\rangle_1 & \cdots & |\alpha'_N\rangle_N \end{vmatrix} = \sqrt{\frac{1}{N!}}\det(\alpha').$$

Next we consider the subspace defined by the spinorbitals $|\alpha'_1\rangle, \cdots |\alpha'_N\rangle$. Let $|\alpha_1\rangle, \cdots |\alpha_N\rangle$ be an alternative basis for the same subspace. Using the closure relation we define the basis transformation

$$|\alpha'_j\rangle = \sum_{i=1}^{N} |\alpha_i\rangle\langle\alpha_i|\alpha'_j\rangle = \sum_{i=1}^{N} U_{ij}|\alpha_i\rangle.$$

Since $\langle\alpha'_j|\alpha_i\rangle = \langle\alpha_i|\alpha'_j\rangle^*$ this is a unitary transformation. Applied to the matrix α' we have

$$\alpha' = U\alpha = \begin{pmatrix} \langle\alpha_1|\alpha'_1\rangle & \cdots & \langle\alpha_N|\alpha'_1\rangle \\ \vdots & \cdots & \vdots \\ \langle\alpha_1|\alpha'_N\rangle & \cdots & \langle\alpha_N|\alpha'_N\rangle \end{pmatrix} \begin{pmatrix} |\alpha_1\rangle_1 & \cdots & |\alpha_1\rangle_N \\ \vdots & \cdots & \vdots \\ |\alpha_N\rangle_1 & \cdots & |\alpha_N\rangle_N \end{pmatrix}.$$

Using the properties of determinants (see Appendix M.2) we find

$$\det(\alpha') = \det(U\alpha) = \det(U)\det(\alpha) = e^{i\xi}\det(\alpha),$$

where ξ is a real number. This expression shows that (up to a phase factor) the Slater determinant is invariant under unitary transformation, $|\psi_{\alpha'}\rangle = e^{i\xi}|\psi_\alpha\rangle$; the phase factor is of no consequence because it does not affect the expectation values. □

9.1.4 Slater determinants - parity and electric-dipole matrix elements

In Section 2.5.1 we found that electric-dipole transitions require a change parity of the atomic state. This selection rule was derived for one-electron atoms. For many-electron atoms this can be different. Therefore, we reconsider the dipole operator as well as the parity of many-electron states.

The *electric-dipole operator* of an N electron atom is given by

$$\mathbf{D} = -\,e\sum_{i=1}^{N}\mathbf{r}_i = -ea\rho\sum_{i=1}^{N}\hat{\mathbf{r}}_i. \tag{9.36}$$

Changing the radius vectors of all electrons from $\mathbf{r}_i$ to $-\mathbf{r}_i$, with $i \in \{1, N\}$, we find that the total dipole operator has *odd* parity; i.e., also in the many-electron electron case electric-dipole transitions require a change parity of the atomic state.

Turning to the states, we note that Slater determinants are linear combinations of products of single particle spinorbitals. As the parity of spinorbital $|\alpha_\kappa\rangle$ is $(-1)^{l_\kappa}$, the parity of the full Slater determinant is given by

$$(-1)^{\sum_\kappa l_{.\kappa}} = \prod_\kappa (-1)^{l_\kappa}. \tag{9.37}$$

This expression shows that the parity of Slater determinant is even unless $\sum_\kappa l_{.\kappa} =$ odd. Phrased differently, the parity is even except for atoms with an odd number of electrons in odd-parity states. Only in the case of one-electron atoms the total angular momentum is decisive for the parity of the many-electron state. For this reason, in the case of many-electron atoms, the parity of *odd-parity* total angular momentum states is explicitly indicated in the spectroscopic notation by an upper index o. In the case of even parity the notation remains unchanged; e.g.,

$$1s^2 2p\,{}^2P \to 1s^2 2p\,{}^2P^o \tag{9.38a}$$

$$npnd\,{}^3D \to npnd\,{}^3D^o \quad \text{and} \qquad np^2\,{}^3D \to np^2\,{}^3D. \tag{9.38b}$$

9.2 Matrix elements of operators between Slater determinants

Dealing with systems of more than one electron means dealing with many-body operators and antisymmetrized N-body states. At first sight it may seem a complicating factor to deal with wavefunctions in the form of Slater determinants and in a way it is, but fortunately a number of simplifying expressions may be derived relating the properties of N-body states to those of single electrons, pairs, triples, *etc.*. It is the purpose of the present section to derive a number of such expressions for future use. We consider the matrix elements for common operator types in combination with antisymmetric N-electron basis states $|\psi_\alpha\rangle = |\alpha_1, \cdots, \alpha_N\rangle$, where the α_κ, with $\kappa \in \{1, \cdots, N\}$, correspond to one-electron spinorbitals.

9.2.1 One-body operators

First we consider the matrix elements of a sum of *one-body operators*,

$$Q_1 = \sum_{i=1}^{N} q_i, \tag{9.39}$$

where the operator q_i acts only on the electron with index $i \in \{1, \cdots, N\}$. A good example of an operator of this type is the Schrödinger Hamiltonian for electrons in the unscreened Coulomb field of the nucleus. Using Eq. (9.23) the most general matrix element of Q_1 with determinantal wavefunctions is of the form

$$\langle\psi_{\alpha'}|Q_1|\psi_\alpha\rangle = \frac{1}{N!}\sum_{i=1}^{N}\sum_{P,P'}(-1)^{p+p'}(\psi_{\alpha'}|P' q_i P|\psi_\alpha), \tag{9.40}$$

where $|\psi_\alpha) \equiv |\alpha_1, \cdots, \alpha_N)$ is the non-symmetrized product state in standard order; p and p' are the parities of the permutations P and P', respectively. In view of the orthogonality of the spinorbitals

$|\alpha_\kappa\rangle$ the matrix elements $(\psi_{\alpha'}|P'q_iP|\psi_\alpha) \equiv (\alpha_1, \cdots, \alpha_{\kappa'}, \cdots \alpha_N|P'q_iP|\alpha_1, \cdots, \alpha_\kappa, \cdots \alpha_N)$ are zero for all possible permutations P and P' whenever $|\psi_\alpha\rangle$ and $|\psi_{\alpha'}\rangle$ differ in *more than one* pair of spinorbitals.

- *Off-diagonal matrix elements differing in one pair.* Let $|\psi_\alpha\rangle$ and $|\psi_{\alpha'}\rangle$ differ in one pair of spin orbitals, α_κ and $\alpha_{\kappa'}$. Then, for every value of $i \in \{1, \cdots, N\}$ there are $(N-1)!$ permutations $P'|\alpha_1, \cdots, \alpha_{\kappa'}, \cdots \alpha_N)$ for which $\alpha_{\kappa'}$ appears on position i. For each of these permutations there is exactly one permutation $P|\alpha_1, \cdots, \alpha_\kappa, \cdots \alpha_N)$ for which also α_κ appears on position i while, in addition, $(\psi_{\alpha'}|P'q_iP|\psi_\alpha) \neq 0$. For this permutation the N-body matrix elements $(\psi_{\alpha'}|P'q_iP|\psi_\alpha)$ reduce to a one-body matrix element involving only electron i,

$$(\psi_{\alpha'}|P'q_iP|\psi_\alpha) = \langle\alpha_{\kappa'}|q_i|\alpha_\kappa\rangle_i. \tag{9.41}$$

  Importantly, the sign $(-1)^{p+p'}$ corresponding to P and P' has the same value for all values of i, $+1$ or -1 depending on the ordering convention. Further, also the matrix elements $\langle\alpha_{\kappa'}|q_i|\alpha_\kappa\rangle_i$ are the same for all electrons; hence, without loss of generality we can drop the particle index and write[1]

$$\langle\alpha_{\kappa'}|q_i|\alpha_\kappa\rangle_i = \langle\alpha_{\kappa'}|q|\alpha_\kappa\rangle. \tag{9.42}$$

  Summing $(\psi_{\alpha'}|P'q_iP|\psi_\alpha)$ over $i \in \{1, \cdots, N\}$ and over all permutations P, P' we arrive at $N(N-1)! = N!$ nonzero contributions of equal value $(-1)^{p+p'}\langle\alpha_{\kappa'}|q|\alpha_\kappa\rangle$ and Eq. (9.40) reduces to a single one-body matrix element,

$$\langle\psi_{\alpha'}|Q_1|\psi_\alpha\rangle = \langle\alpha_{\kappa'}|q|\alpha_\kappa\rangle\frac{1}{N!}\sum_{i=1}^{N}\sum_{P}{}'(-1)^{p+p'} = \pm\langle\alpha_{\kappa'}|q|\alpha_\kappa\rangle, \tag{9.43}$$

  where the sign depends on the ordering convention. The prime indicates that the permutation sum excludes, for a given value of i, all permutations P in which α_κ appears on position i but $(\psi_{\alpha'}|P'q_iP|\psi_\alpha) = 0$. We thus established that an operator of the type Q_1 can couple two one-electron states. Note that the corresponding matrix element does not depend on the particle index. This reflects the indistinguishability of identical particles.

- *Diagonal matrix elements.* In this case $|\psi_\alpha\rangle = |\psi_{\alpha'}\rangle$. Adopting the same approach as for the off-diagonal elements we note that in the diagonal case the N-body matrix elements are only nonzero if $P' = P$. Again we find that for every value of $i \in \{1, \cdots, N\}$ there are $(N-1)!$ permutations $P|\alpha_1, \cdots, \alpha_\kappa, \cdots \alpha_N)$ for which α_κ appears on position i while $(\psi_\alpha|Pq_iP|\psi_\alpha) \neq 0$ but in the present case this is possible *for each value of* $\kappa \in \{1, \cdots, N\}$. For each set of $(N-1)!$ permutations the N-body matrix elements reduce to the same one-body matrix element, $(\psi_\alpha|Pq_iP|\psi_\alpha) = (-1)^{2p}\langle\alpha_\kappa|q|\alpha_\kappa\rangle = \langle\alpha_\kappa|q|\alpha_\kappa\rangle$. Summing $(\psi_\alpha|Pq_iP|\psi_\alpha)$ over $i \in \{1, \cdots, N\}$ and over all permutations P we have *this time for each* $\kappa \in \{1, \cdots, N\}$ again $N(N-1)! = N!$ nonzero terms of equal value $\langle\alpha_\kappa|q|\alpha_\kappa\rangle$ and Eq. (9.43) is replaced by

$$\langle\psi_\alpha|Q_1|\psi_\alpha\rangle = \sum_{\kappa=1}^{N}\langle\alpha_\kappa|q|\alpha_\kappa\rangle. \tag{9.44}$$

  This result is intuitively clear: the expectation value of the operator Q_1 represents the sum of the contributions of all spin-orbitals contained in the many-body state $|\alpha_1, \cdots, \alpha_N\rangle$. Again the result is independent of the particle indices as expected for identical particles.

---

[1] For example for the hydrogenic ns orbitals we calculate $\langle ns|Z/\rho_i|ns\rangle = \int |\phi_{ns}(\rho_i)|^2\rho_i d\rho_i = Z^2/n^2$.

9.2.2 Two-body operators

Next we consider the matrix elements of a sum of *two-body operators*,

$$Q_2 = \tfrac{1}{2} \sum_{i,j=1}^{N}{}' q_{ij} = \sum_{i>j}^{N} q_{ij}, \tag{9.45}$$

where the operator q_{ij} acts only on the electrons with indices $i, j \in \{1, \cdots, N\}$ and the sum runs over all *different* pairs. The prime excludes the case $i = j$ and the factor $\frac{1}{2}$ corrects for double counting of pairs. Alternatively one can sum over all pairs with $i > j$. A good example of such an operator is the electrostatic repulsion (7.10) between electrons in an atom. Using Eq. (9.23) the most general matrix element of Q_2 with determinantal wavefunctions is of the form

$$\langle \psi_{\alpha'} | Q_2 | \psi_\alpha \rangle = \frac{1}{N!} \frac{1}{2} \sum_{i,j=1}^{N}{}' \sum_{P,P'} (-1)^{p+p'} (\psi_{\alpha'} | P' q_{ij} P | \psi_\alpha), \tag{9.46}$$

where $|\psi_\alpha) \equiv |\alpha_1, \cdots, \alpha_N)$ is the N-body product state in standard order. In view of the orthogonality of the spin-orbitals we have $(\psi_{\alpha'}|P' q_{ij} P|\psi_\alpha) = 0$ for all possible permutations P and P' whenever $|\psi_\alpha\rangle$ and $|\psi_{\alpha'}\rangle$ differ in *more than two* pairs of spin orbitals.

- *Off-diagonal matrix elements differing in two pairs.* Let $|\psi_\alpha\rangle$ and $|\psi_{\alpha'}\rangle$ differ by two pairs of spinorbitals, $\alpha_\kappa, \alpha_\nu$ and $\alpha_{\kappa'}, \alpha_{\nu'}$, respectively. For each pair of indices $i, j \in \{1, \cdots, N\}$ with $i \neq j$, there are $2\,(N-2)!$ permutations $|\alpha_1, \cdots, \alpha_\kappa, \alpha_\nu, \cdots \alpha_N) = P|\alpha_1, \cdots \alpha_N)$ for which α_κ appears on the position i and α_ν on j (those we call P_1) or *vice versa* (those we call P_2). For each of these permutations there is exactly *one* permutation, P_1' or P_2', for which $\alpha_{\kappa'}$ and $\alpha_{\nu'}$ appear, respectively, on the position i and j in $(\psi_{\alpha'}|P'$, while in addition, $(\psi_{\alpha'}|P' q_{ij} P|\psi_\alpha) \neq 0$. With these *two* permutations the N-body matrix element reduces to *two* two-body matrix element for the electrons i and j. The first is

$$\begin{aligned} (\psi_{\alpha'}|P_1' q_{ij} P_1|\psi_\alpha) &= (-1)^{p+p_1} \left(\alpha_{\kappa'}, \alpha_{\nu'} | q_{ij} | \alpha_\kappa, \alpha_\nu\right)_{i,j} \\ &= (-1)^{p+p_1} (\alpha_{\kappa'}, \alpha_{\nu'} | q_{12} | \alpha_\kappa, a_\nu). \end{aligned} \tag{9.47}$$

  The permutation P_2 gives $(-1)^{p+p_2} (\alpha_{\kappa'}, \alpha_{\nu'}|q_{12}|\alpha_\nu, a_\kappa)$. The sign $(-1)^{p+p_2} = -(-1)^{p+p_1}$ has the same value for all values of i. Summing $(\psi_{\alpha'}|P' q_{ij} P|\psi_\alpha)$ over the $\frac{1}{2}N(N-1)$ different pairs $i, j \in \{1, \cdots, N\}$ and over all permutations P, P' we obtain $\frac{1}{2}N\,(N-1)\,2(N-2)! = N!$ equal nonzero terms and Eq. (9.46) becomes

$$\langle \psi_{\alpha'} | Q_2 | \psi_\alpha \rangle = \left[(\alpha_{\kappa'}, \alpha_{\nu'} | q_{12} | \alpha_\kappa, \alpha_\nu) - (\alpha_{\kappa'}, \alpha_{\nu'} | q_{12} | \alpha_\nu, \alpha_\kappa) \right] \frac{1}{N!} \frac{1}{2} \sum_{i,j=1}^{N}{}' \sum_{P}{}' (-1)^{p+p_1'} \tag{9.48}$$

$$= \pm \left[(\alpha_{\kappa'}, \alpha_{\nu'} | q_{12} | \alpha_\kappa, \alpha_\nu) - (\alpha_{\kappa'}, \alpha_{\nu'} | q_{12} | \alpha_\nu, \alpha_\kappa) \right], \tag{9.49}$$

  with the overall sign depending on the ordering convention. The prime on the permutation sum indicates that the sum excludes, for given values of i and j, all permutations P in which α_κ and α_ν appear on the positions i or j but $(\psi_{\alpha'}|P' q_i P|\psi_\alpha) = 0$. We thus found that an operator of the type Q_2 can couple two pairs of spinorbitals and that the corresponding matrix elements do not depend on the particle indices of the electrons involved.

- *Off-diagonal matrix elements differing in one pair.* Let $|\psi_\alpha\rangle$ and $|\psi_{\alpha'}\rangle$ differ by one pair of spin orbitals, α_ν and $\alpha_{\nu'}$. For each pair $i, j \in \{1, \cdots, N\}$ with $i \neq j$ and each $\kappa \in \{1, \cdots, N\}$ we have, like in the previous case, $2\,(N-2)!$ permutations $|\alpha_1, \cdots, \alpha_\kappa, \alpha_\nu, \cdots \alpha_N) = P|\psi_\alpha)$ for which α_κ appears on the position i and α_ν on j (those we call again P_1) or *vice versa* (those we call again P_2). For each of these permutations there is exactly *one* permutation, P_1' or P_2', for which α_κ and $\alpha_{\nu'}$ appear, respectively, on the position i and j in $(\psi_{\alpha'}|P'$, while in addition, $(\psi_{\alpha'}|P'q_{ij}P|\psi_\alpha) \neq 0$. The corresponding *two* two-body matrix elements are $(\psi_{\alpha'}|P'q_{ij}P|\psi_\alpha) = (-1)^{p+p_1}(\alpha_\kappa, \alpha_{\nu'}|q_{12}|\alpha_\kappa, \alpha_\nu)$ and $-(-1)^{p+p_1}(\alpha_\kappa, \alpha_{\nu'}|q_{12}|\alpha_\nu, \alpha_\kappa)$. Summing $(\psi_{\alpha'}|P'q_{ij}P|\psi_\alpha)$ over the $\frac{1}{2}N(N-1)$ different electron pairs (i,j) and over all permutations P, P' we have *this time for each* $\kappa \in \{1, \cdots, N\}$ again $\frac{1}{2}N\,(N-1)\,2(N-2)! = N!$ equal terms and Eq. (9.49) is replaced by

$$\langle\psi_{\alpha'}|Q_2|\psi_\alpha\rangle = \pm\sum_{\kappa=1}^{N}\left[(\alpha_\kappa, \alpha_{\nu'}|q_{12}|\alpha_\kappa, \alpha_\nu) - (\alpha_\kappa, \alpha_{\nu'}|q_{12}|\alpha_\nu, \alpha_\kappa)\right], \tag{9.50}$$

with the overall sign depending again on the ordering convention. We found that an operator of the type Q_2 can also give rise to the coupling of one pair of spinorbitals.

- *Diagonal matrix elements.* In this case $|\psi_\alpha\rangle = |\psi_{\alpha'}\rangle$. Continuing with the approach adopted above we note that for each pair of electron indices $i, j \in \{1, \cdots, N\}$ with $i \neq j$ and each pair of state indices $\kappa, \nu \in \{1, \cdots, N\}$ there are $2\,(N-2)!$ permutations $|\alpha_1, \cdots, \alpha_\kappa, \alpha_\nu, \cdots \alpha_N) = P|\psi_\alpha)$ for which α_κ appears on the position i and α_ν on j (those we call again P_1) or *vice versa* (those we call again P_2). For each of these permutations there is exactly *one* permutation, P_1' or P_2', for which α_κ and α_ν appear, respectively, on the position i and j in $(\psi_{\alpha'}|P'$, while in addition, $(\psi_{\alpha'}|P'q_{ij}P|\psi_\alpha) \neq 0$. The corresponding *two* two-body matrix elements give rise to a *direct* and an *exchange* contribution, given by $(\psi_\alpha|P'q_{ij}P|\psi_\alpha) = (\alpha_\kappa, \alpha_\nu|q_{12}|\alpha_\kappa, \alpha_\nu)$ and $-(\alpha_\kappa, \alpha_\nu|q_{12}|\alpha_\kappa, \alpha_\nu)$, respectively. Summing $(\psi_\alpha|P'q_{ij}P|\psi_\alpha)$ over the $\frac{1}{2}N(N-1)$ different electron pairs (i,j) and over all permutations P, P' we have *this time for each* $\kappa, \nu \in \{1, \cdots, N\}$, with $\kappa \neq \nu$, again $\frac{1}{2}N\,(N-1)\,2(N-2)! = N!$ equal contributions and obtain

$$\langle\psi_\alpha|Q_2|\psi_\alpha\rangle = \tfrac{1}{2}\sum_{\kappa,\nu=1}^{N}\left[(\alpha_\kappa, \alpha_\nu|q_{12}|\alpha_\kappa, \alpha_\nu) - (\alpha_\kappa, \alpha_\nu|q_{12}|\alpha_\nu, \alpha_\kappa)\right]. \tag{9.51}$$

Interestingly, for $\nu = \kappa$ the direct and exchange terms are equal. Therefore, the terms with $\nu = \kappa$ can be excluded from the summation,

$$\begin{aligned}\langle\psi_\alpha|Q_2|\psi_\alpha\rangle &= \tfrac{1}{2}\sum_{\kappa,\nu=1}^{N}{}'\left[(\alpha_\kappa, \alpha_\nu|q_{12}|\alpha_\kappa, \alpha_\nu) - (\alpha_\kappa, \alpha_\nu|q_{12}|\alpha_\nu, \alpha_\kappa)\right],\\ &\equiv \sum_{\kappa>\nu}^{N}\left[(\alpha_\kappa, \alpha_\nu|q_{12}|\alpha_\kappa, \alpha_\nu) - (\alpha_\kappa, \alpha_\nu|q_{12}|\alpha_\nu, \alpha_\kappa)\right].\end{aligned} \tag{9.52}$$

which shows that the expectation value of the operator Q_2 represents the sum of the contributions of the $\frac{1}{2}N(N-1)$ possible pairs of states.

Problem 9.5. Two electrons are said to be in a *paired spin state* if one of the electrons has spin up, $|\uparrow\rangle$, and the other spin down, $|\downarrow\rangle$. Show that for *paired* spins the exchange terms cancel for a spin-independent two-body interaction,

$$(\alpha_\kappa, \alpha_\nu|q_{12}|\alpha_\nu, \alpha_\kappa) = 0 \text{ for } m_s^\kappa \neq m_s^\nu.$$

Solution. For a spin-independent two-body interaction the spin dependence factors out,

$$(\alpha_\kappa, \alpha_\nu|q_{12}|\alpha_\nu, \alpha_\kappa) = (u_\kappa, u_\nu|q_{12}|u_\nu, u_\kappa)\delta_{m_s^\kappa, m_s^\nu}.$$

Hence, for paired spins ($m_s^\kappa \neq m_s^\nu$) the matrix element vanishes. □

9.3 Occupation number representation

9.3.1 Introduction

The notation of the previous section calls for simplification. This is realized by introducing *construction operators* which satisfy an algebra that enforces the quantum statistics. The first construction operators were introduced by Paul Dirac in 1927 [32]. Starting from Maxwell's equations, Dirac quantized the electromagnetic field by treating the eigenmodes of the field as independent harmonic oscillators. The excitation level of the oscillator represents the mode occupation of the field. The raising (lowering) operators of the oscillator serve to construct the field by creation (annihilation) of photons, the quanta of the radiation field, which occupy the modes. The commutation relations between the operators define the algebra that enforces the Bose statistics of the field. This marks the start of quantum field theory. In the same year Pascual Jordan and Oskar Klein showed that the method could be extended to describe quantum many-body systems of bosons satisfying the Schrödinger equation [62]. Adapting the algebra, Jordan and Wigner further extended the method to describe quantum many-body systems of interacting fermionic particles [63]. The above sequence of seminal papers is not complete without the name of Vladimir Fock, who emphasized in 1932 the use of field operators (construction operators for configuration space) [44]. This approach leads to an operator identity resembling the Schrödinger equation, which explains the unfortunate name *second quantization* for the *construction operator formalism*. In following sections we give a concise introduction into the construction operator formalism for quantum many-body systems. As electrons are fermions, we focus on the fermionic case. For a systematic introduction the lecture notes of Jan de Boer are recommended [29].

9.3.2 Number states in the N-body Hilbert space

We start by introducing a new representation, the *occupation number representation*. In this representation we keep track of the occupation of the spinorbitals. To introduce this notation we start with a seemingly innocent change in notation of the Slater determinants,

$$|\psi_\alpha\rangle \equiv |\alpha_r, \cdots, \alpha_s, \cdots, \alpha_t\rangle = |1_r, \cdots, 1_s, \cdots, 1_t\rangle, \tag{9.53}$$

where by $1_r, \cdots$ we indicate that we have 1 electron in the spinorbitals $|\alpha_r\rangle, \cdots$, given in standard order. If we have N electrons we have

$$1_r + \cdots + 1_s + \cdots + 1_t = N. \tag{9.54}$$

If the state $|\alpha_\nu\rangle$ is *not* occupied we are of course free to write 0_ν to indicate an empty orbital. At first sight this may not appear as particularly useful but, as we shall see, an enormous simplification of notation can be realized by introducing a representation in which we specify the occupation numbers of all possible spinorbitals (given in standard order). In this representation an *arbitrary* N-electron Slater determinant $|\psi_\gamma\rangle$ is written as

$$|\psi_\gamma\rangle \equiv |n_1, n_2, \cdots\rangle, \tag{9.55}$$

where $n_s \in \{0, 1\}$ is the occupation number of the state $|\alpha_s\rangle$, with $n_r + n_s + \cdots + n_t = N$. In this notation the states are called *number states*, which are the basis states of the occupation number representation (see next section). The N-electron number states have normalization

$$\langle n_1', n_2', \cdots | n_1, n_1, \cdots\rangle = \delta_{n_1,n_1'}\delta_{n_2,n_2'}\cdots \tag{9.56}$$

and closure

$$\sum_{n_1,n_2\cdots}{}' |n_1, n_2, \cdots\rangle \langle n_1, n_2, \cdots| = \mathbb{1}, \tag{9.57}$$

where $n_1, n_2, \cdots$ is either 0 or 1 and the prime indicates that the sum over all occupations equals the total number of particles, $n_1 + n_2 + \cdots = N$. This is called closure within $\mathbf{H}^N$.

9.3.3 Number states in Grand Hilbert space - construction operators

An important generalization of number states is obtained by interpreting the occupation numbers $n_1, n_2, \cdots$ as the eigenvalues of the *number operators* $\hat{n}_1, \hat{n}_2, \cdots$,

$$\hat{n}_s|n_1, n_2, \cdots, n_s, \cdots\rangle = n_s|n_1, n_2, \cdots, n_s, \cdots\rangle, \tag{9.58}$$

where $n_1, n_2, \cdots$ is either 0 or 1. The eigenstates $|n_1, n_2, \cdots, n_s, \cdots\rangle$ form the basis of the *occupation number representation.* With this definition the expectation value of $\hat{n}_s$ is *exclusively* determined by the occupation number n_s of the state $|s\rangle$; it is independent of the occupation of all other states; i.e., independent of N. Therefore, the number operators may be interpreted as acting in a *Grand Hilbert space*, also known as *Fock space*, which is the direct sum of the Hilbert spaces of all possible atom number states of a gas cloud, including the vacuum,

$$\mathbf{H}^{Gr} = \mathbf{H}^0 \oplus \mathbf{H}^1 \oplus \cdots \oplus \mathbf{H}^N \oplus \cdots .$$

By adding an atom we shift from $\mathbf{H}^N$ to $\mathbf{H}^{N+1}$, analogously we shift from $\mathbf{H}^N$ to $\mathbf{H}^{N-1}$ by removing an atom. As long as this does not affect the occupation of the single-particle state $|s\rangle$ the operator $\hat{n}_s$ yields the same result. Hence, the *number states* from $\mathbf{H}^N$ may be reinterpreted as number states $|n_1, n_2, \cdots\rangle$ within $\mathbf{H}^{Gr}$ by specifying the occupations of *all* single-particle states. For example, for the N-electron state $|\psi_\alpha\rangle \equiv |\alpha_r, \cdots, \alpha_s, \cdots, \alpha_t\rangle$ we have $n_r = 1$, $n_s = 1$, $\cdots$, $n_t = 1$ and all other occupation numbers are zero.

The basic operators in Grand Hilbert space are the *construction operators.* In particular the operator $\hat{a}_s^\dagger$ is called a *creation operator* and defined by

$$\hat{a}_s^\dagger|1_r, \cdots, 0_s, \cdots, 1_t\rangle = |1_s, 1_r, \cdots, 0_s, \cdots, 1_t\rangle = (-1)^p\,|1_r, \cdots, 1_s, \cdots, 1_t\rangle \tag{9.59a}$$

$$\hat{a}_s^\dagger|1_r, \cdots, 1_s, \cdots, 1_t\rangle = 0, \tag{9.59b}$$

where $(-)^p$ yields $+1$ or -1 depending on whether it takes an even or an odd permutation P between *occupied* states to bring the occupation number 1_s to the empty position in the normal order of states; with the second line we assure that the state $|\alpha_s\rangle$ cannot be occupied more than once. Likewise the operator $\hat{a}_s$ is called an *annihilation operator* and defined by

$$\hat{a}_s\,|1_r, \cdots, 1_s, \cdots, 1_t\rangle = (-1)^p\,\hat{a}_s\,|1_s, 1_r, \cdots, 0_s, \cdots, 1_t\rangle = (-1)^p\,|1_r, \cdots, 0_s, \cdots, 1_t\rangle \tag{9.60a}$$

$$\hat{a}_s\,|1_r, \cdots, 0_s, \cdots, 1_t\rangle = 0, \tag{9.60b}$$

where $(-)^p$ yields $+1$ or -1 depending on whether it takes an even or an odd permutation P between *occupied* states to bring the occupation number 1_s the first position in the Slater determinant (without changing the order of the other states); the second line assures that an electron cannot be cannot be removed from the state $|\alpha_s\rangle$ more than once. Let us have a look at a few examples: with the creation operators we obtain $\hat{a}_s^\dagger\,|0_q, 0_s, \cdots\rangle = +\,|0_q, 1_s, \cdots\rangle$, $\hat{a}_s^\dagger\,|1_q, 0_s, \cdots\rangle = -\,|1_q, 1_s, \cdots\rangle$, where we used the alphabetic order to represent the normal order. Analogously, we obtain with the annihilation operators $\hat{a}_s\,|0_q, 1_s, \cdots\rangle = |0_q, 0_s, \cdots\rangle$ and $\hat{a}_s\,|1_q, 1_s, \cdots\rangle = -\,|1_q, 0_s, \cdots\rangle$.

The basic actions of the construction operators can be summarized as

$$\hat{a}_s^\dagger|n_s, \cdots\rangle \equiv \sqrt{n_s+1}|n_s+1, \cdots\rangle \tag{9.61a}$$

$$\hat{a}_s|n_s, \cdots\rangle \equiv \sqrt{n_s}|n_s-1, \cdots\rangle, \tag{9.61b}$$

with $n_s \in \{0, 1\}$. The creation operators transform an antisymmetrized N-body eigenstate in $\mathbf{H}^N$ into an antisymmetrized $N+1$ body eigenstate in $\mathbf{H}^{N+1}$. Analogously, the annihilation operators transform an antisymmetrized N-body eigenstate in $\mathbf{H}^N$ into an antisymmetrized $N-1$ body eigenstate in $\mathbf{H}^{N-1}$. Further, we introduce the commutation relations [1]

$$\{\hat{a}_r, \hat{a}_s^\dagger\} = \delta_{rs}\ ; \qquad \{\hat{a}_r, \hat{a}_s\} = \{\hat{a}_r^\dagger, \hat{a}_s^\dagger\} = 0, \tag{9.62}$$

---

[1] Note that we use the curly bracket convention for the anti-commutator: $\{a, b\} = ab + ba$.

which serve to enforce the Pauli principle as embodied by Eq. (9.59b) and reflect the antisymmetry of the Slater determinants. From Eqs. (9.61) and (9.62) follow the following properties of the construction operators and the number states:

- the construction operators $\hat{a}_s^\dagger$ and $\hat{a}_s$ are hermitian conjugates,
$$\langle n_s+1|\hat{a}_s^\dagger|n_s\rangle = \langle n_s|\hat{a}_s|n_s+1\rangle^* = \sqrt{n_s+1}. \tag{9.63}$$
Hence, *when acting on the bra side* $\hat{a}_s^\dagger$ and $\hat{a}_s$ change their role, $\hat{a}_s^\dagger$ becomes the annihilation operator and $\hat{a}_s$ the creation operator. Note that Eq. (9.63) only has physical significance for $n_s = 0$ because double occupation of electronic states violates the Pauli principle.

- the number operator is given by $\hat{n}_s = \hat{a}_s^\dagger \hat{a}_s$,
$$\hat{n}_s|n_s,\cdots\rangle = \hat{a}_s^\dagger\hat{a}_s|n_s,\cdots\rangle \equiv \sqrt{n_s}\hat{a}_s^\dagger|n_s-1,\cdots\rangle = n_s|n_s,\cdots\rangle. \tag{9.64}$$

- an absent particle cannot be annihilated. This is embodied by Eq. (9.60b),
$$\hat{a}_s|n_s,\cdots\rangle \equiv \sqrt{n_s}|n_s-1,\cdots\rangle = 0 \quad \text{for} \quad n_s = 0. \tag{9.65}$$

- the Pauli principle is satisfied. This is embodied by Eq. (9.59b),
$$\hat{a}_s\hat{a}_s^\dagger|n_s,\cdots\rangle = (1-\hat{a}_s^\dagger\hat{a}_s)|n_s,\cdots\rangle = (1-n_s)|n_s,\cdots\rangle = 0 \quad \text{for} \quad n_s = 1. \tag{9.66}$$

- *any* N-body state $|\psi_\gamma\rangle = |1_r,\cdots,1_s,\cdots,1_t\rangle$ can be constructed by repetitive use of a set of creation operators
$$|\psi_\gamma\rangle = \prod_{s\in\gamma} \hat{a}_s^\dagger\,|0\rangle\,, \tag{9.67}$$
where the index $s \in \gamma = \{q,\cdots,r,\cdots,t\}$ points to the set of one-body states to be populated in normal order and $|0\rangle \equiv |0_1, 0_2,\cdots\rangle$ is called the *vacuum state.*

- also the vacuum state is unit normalized,
$$\langle 0|0\rangle = \left\langle 1_s|\hat{a}_s^\dagger\hat{a}_s|1_s\right\rangle = \langle 1_s|\hat{n}_s|1_s\rangle = \langle s|s\rangle = 1, \tag{9.68}$$
where α_s is an arbitrary orbital.

- the number states created from the vacuum are *antisymmetric.* This follows from the commutation relation $\{\hat{a}_r^\dagger, \hat{a}_s^\dagger\} = 0$,
$$|1_r, 1_s\rangle = \hat{a}_r^\dagger\hat{a}_s^\dagger\,|0\rangle = -\hat{a}_s^\dagger\hat{a}_r^\dagger\,|0\rangle = -|1_s, 1_r\rangle. \tag{9.69}$$

Thus we have obtained the *occupation number representation.* By extending $\mathbf{H}^N$ to $\mathbf{H}^{Gr}$ the definition of the number states and their normalization has remained unchanged,
$$\langle n_1', n_2',\cdots|n_1, n_2,\cdots\rangle = \delta_{n_1,n_1'}\delta_{n_2,n_2'}\cdots\,. \tag{9.70}$$

Importantly, by turning to $\mathbf{H}^{Gr}$ the condition on particle conservation is lost. This has the very convenient consequence that in the closure relation (9.57) the restricted sum may be replaced by an *unrestricted* sum, thus allowing for all possible values of N,
$$\sum_{n_1,n_2\cdots} |n_1,n_2,\cdots\rangle\,\langle n_1,n_2,\cdots| = \mathbb{1}, \tag{9.71}$$
where $n_1, n_2,\cdots$ can take the values 0 or 1. This is called closure within $\mathbf{H}^{Gr}$.

Problem 9.6. Show that the following commutation relations hold
$$\left[\hat{n}_q, \hat{a}_s^\dagger\right] = +\hat{a}_s^\dagger\delta_{qs} \quad \text{and} \quad [\hat{n}_q, \hat{a}_s] = -\hat{a}_s\delta_{qs}\,. \tag{9.72}$$

9.3.4 Operators in the occupation number representation

The real added value of the occupation number representation is in the calculation of the interaction terms of the atomic Hamiltonian. In the present section we show that the extension of one-body operators into Grand Hilbert space is given by

$$Q_1 = \sum_i q_i \quad \rightarrow \quad \hat{Q}_1 = \sum_{s,s'} \langle s'|q|s\rangle \hat{a}_{s'}^\dagger \hat{a}_s, \tag{9.73}$$

where the sum in the expression for Q_1 runs over the *particle index* and the sums in the expression for $\hat{Q}_1$ run over the *state index* of all one-body states (occupied or not) and $\hat{a}_s^\dagger$ and $\hat{a}_s$ are the construction operators that change the occupation of the state $|\alpha_s\rangle$. Likewise the extension of two-body operators is given by

$$Q_2 = \tfrac{1}{2}\sum_{i,j}{}' q_{ij} \quad \rightarrow \quad \hat{Q}_2 = \tfrac{1}{2}\sum_{t,t'}\sum_{s,s'} (s',t'|q_{12}|s,t)\hat{a}_{s'}^\dagger \hat{a}_{t'}^\dagger \hat{a}_t \hat{a}_s. \tag{9.74}$$

To demonstrate the validity of these simple expressions we rederive the expression of Sections 9.2.1 and 9.2.2. As we shall see, in the occupation representation these expressions are obtained with a minimal effort by straightforward application of the operator algebra. The key idea is based on the orthonormality relation

$$\langle \psi_{\alpha'}|\psi_\alpha\rangle = \langle n_1', n_2', \cdots |n_1, n_2, \cdots\rangle = \delta_{n_1,n_1'}\delta_{n_2,n_2'}\cdots . \tag{9.75}$$

In the language of the occupation number representation for N-electron atoms this means that the inner product is zero unless every state that is created on the ket side is annihilated on the bra side,

$$\langle \alpha_1, \cdots \alpha_N|\alpha_1, \cdots \alpha_N\rangle = \langle 0|\hat{a}_N \cdots \hat{a}_1 \hat{a}_1^\dagger \cdots \hat{a}_N^\dagger|0\rangle = 1. \tag{9.76}$$

9.3.4.1 One-body operators:

- *Diagonal matrix elements.*

  $$\langle \psi_\alpha|\hat{Q}_1|\psi_\alpha\rangle = \sum_{s,s'} \langle s'|q|s\rangle \langle 0|\hat{a}_N \cdots \hat{a}_1 \hat{a}_{s'}^\dagger \hat{a}_s \hat{a}_1^\dagger \cdots \hat{a}_N^\dagger|0\rangle.$$

  In view of the diagonality any one-body state that is destroyed has to be recreated, otherwise the matrix element will be zero by orthonormality of the one-body states. This means that only the following terms contribute:

  $$\hat{Q}_1 = \sum_s \langle s|q|s\rangle \hat{a}_s^\dagger \hat{a}_s = \sum_s \langle s|q|s\rangle \hat{n}_s, \tag{9.77}$$

  which is readily evaluated by summing the contributions of the occupied states $\{|\kappa\rangle\}$,

  $$\langle \psi_\alpha|\hat{Q}_1|\psi_\alpha\rangle = \sum_\kappa \langle \alpha_\kappa|q|\alpha_\kappa\rangle. \tag{9.78}$$

  Here we regained Eq. (9.44).

- *Off-diagonal matrix elements differing in one pair of states* (the pair $\langle\kappa'|$ and $|\kappa\rangle$). The only way in which such matrix elements can be nonzero is if we destroy the state $|\kappa\rangle$ and create the state $|\kappa'\rangle$. This means that only one term contributes,

  $$\hat{Q}_1 = \langle \kappa'|q|\kappa\rangle \hat{a}_{\kappa'}^\dagger \hat{a}_\kappa, \tag{9.79}$$

which is readily evaluated to yield,

$$\langle\psi_{\alpha'}|\hat{Q}_1|\psi_\alpha\rangle = (-)^{p_\kappa + p_{\kappa'}}\langle\alpha_{\kappa'}|q|\alpha_\kappa\rangle, \tag{9.80}$$

which coincides with the result (9.43) with p_κ and $p_{\kappa'}$ representing the orders of the permutations that bring the states $|\alpha_\kappa\rangle$ and $|\alpha_{\kappa'}\rangle$ to the first position in the Slater determinant.

- *Off-diagonal matrix elements differing in more than one pair of states.* In this case we always have
$$\langle\psi_{\alpha'}|\hat{Q}_1|\psi_\alpha\rangle = 0 \tag{9.81}$$
because the operator $\hat{Q}_1$ can at most replace one state by an other.

9.3.4.2 Two-body operators:

- *Diagonal matrix elements* $\langle\psi_\alpha|\hat{Q}_2|\psi_\alpha\rangle$*.* In view of the diagonality, any one-body state that is destroyed has to be recreated. If we annihilate two one-body states, we have two options, first annihilate $|s\rangle$ and then $|t\rangle$ or *vice versa* (note that $a_s a_t|\psi_\alpha\rangle \neq 0$ implies $a_t a_s|\psi_\alpha\rangle \neq 0$). Exploiting this symmetry we obtain the sum of two terms, which leaves us with a single option to recreate the states. We implement this option by first recreating $\langle t|$ and subsequently $\langle s|$ (the inverse order yields the same result by renaming $s \leftrightarrow t$). Summing over all different pairs s and t we obtain
$$\hat{Q}_2 = \tfrac{1}{2}\sum_{t,s}{}'[(s,t|q_{12}|s,t)\hat{a}_s^\dagger\hat{a}_t^\dagger\hat{a}_t\hat{a}_s + (s,t|q_{12}|t,s)\hat{a}_s^\dagger\hat{a}_t^\dagger\hat{a}_s\hat{a}_t], \tag{9.82}$$
where the prime on the summation stands for $t \neq s$. Switching to the number operators, $\hat{n}_t = \hat{a}_t^\dagger\hat{a}_t$, and using the fermionic commutation relations $\{\hat{a}_s, \hat{a}_t^\dagger\} = 0$ and $\{\hat{a}_t, \hat{a}_s\} = 0$ we have $\hat{a}_s^\dagger\hat{a}_t^\dagger\hat{a}_t\hat{a}_s = \hat{a}_s^\dagger\hat{a}_s\hat{a}_t^\dagger\hat{a}_t = \hat{n}_s\hat{n}_t$ and $\hat{a}_s^\dagger\hat{a}_t^\dagger\hat{a}_s\hat{a}_t = -\hat{a}_s^\dagger\hat{a}_s\hat{a}_t^\dagger\hat{a}_t = \hat{n}_s\hat{n}_t$ the expression for $\hat{Q}_2$ becomes
$$\hat{Q}_2 = \tfrac{1}{2}\sum_{t,s}{}'\,[(s,t|q_{12}|s,t) - (s,t|q_{12}|t,s)]\,\hat{n}_s\hat{n}_t. \tag{9.83}$$
This operator is readily evaluated by summing the contributions of the occupied pairs of states $\{|\alpha_\kappa\rangle, |\alpha_\nu\rangle\}$,
$$\langle\psi_\alpha|\hat{Q}_2|\psi_\alpha\rangle = \tfrac{1}{2}\sum_{\kappa,\nu}{}'\,[(\alpha_\kappa,\alpha_\nu|q_{12}|\alpha_\kappa,\alpha_\nu) - (\alpha_\kappa,\alpha_\nu|q_{12}|\alpha_\nu,\alpha_\kappa)]\,. \tag{9.84}$$
Here we regained Eq. (9.52).

- *Off-diagonal matrix elements differing in one pair of states* (the pair $\langle\nu'|$ and $|\nu\rangle$). If we annihilate two occupied one-body states, we have two options, first $|\kappa\rangle$ and then $|\nu\rangle$ or *vice versa*, before creating the state $\langle\nu'|$ and recreating $\langle\kappa|$. This means that for each value of κ only two terms contribute:
$$\hat{Q}_2 = \sum_\kappa{}'[(\kappa,\nu'|q_{12}|\kappa,\nu)\hat{a}_\kappa^\dagger\hat{a}_{\nu'}^\dagger\hat{a}_\nu\hat{a}_\kappa + (\kappa,\nu'|q_{12}|\nu,\kappa)\hat{a}_\kappa^\dagger\hat{a}_{\nu'}^\dagger\hat{a}_\kappa\hat{a}_\nu]. \tag{9.85}$$
Switching to the number operators, $\hat{n}_s = \hat{a}_s^\dagger\hat{a}_s$, and using the commutation relations $\{\hat{a}_\kappa^\dagger, \hat{a}_{\nu'}^\dagger\} = \{\hat{a}_\kappa^\dagger, \hat{a}_\nu\} = 0$ (note that $\nu' \neq \kappa$ and $\nu \neq \kappa$) we have $\hat{a}_\kappa^\dagger\hat{a}_{\nu'}^\dagger\hat{a}_\nu\hat{a}_\kappa = \hat{a}_{\nu'}^\dagger\hat{a}_\nu\hat{n}_\kappa$ and $\hat{a}_\kappa^\dagger\hat{a}_{\nu'}^\dagger\hat{a}_\kappa\hat{a}_\nu = -\hat{a}_{\nu'}^\dagger\hat{a}_\nu\hat{n}_\kappa$ this becomes
$$\langle\psi_{\alpha'}|Q_2|\psi_\alpha\rangle = (-)^{p_\kappa+p_\nu}\sum_\kappa\,[(\alpha_\kappa,\alpha_\nu|q_{12}|\alpha_\kappa,\alpha_\nu) - (\alpha_\kappa,\alpha_\nu|q_{12}|\alpha_\nu,\alpha_\kappa)]\,, \tag{9.86}$$

which coincides with the result (9.50) with p_ν and $p_{\nu'}$ representing the orders of the permutations that bring the states $|\alpha_\nu\rangle$ and $|\alpha_\kappa\rangle$, respectively, to the first column position in the Slater determinant.

- *Off-diagonal matrix elements differing in two pairs of states* (the pairs $\langle\kappa'|, |\kappa\rangle$ and $\langle\nu'|, |\nu\rangle$). If we annihilate two occupied one-body states, we have two option, first $|\kappa\rangle$ and then $|\nu\rangle$ or *vice versa*, before creating the states $\langle\nu'|$ and $\langle\kappa'|$. This means that only two terms contribute:

$$\hat{Q}_2 = (\kappa',\nu'|q_{12}|\kappa,\nu)\hat{a}^\dagger_{\kappa'}\hat{a}^\dagger_{\nu'}\hat{a}_\nu\hat{a}_\kappa + (\kappa',\nu'|q_{12}|\nu,\kappa)\hat{a}^\dagger_{\kappa'}\hat{a}^\dagger_{\nu'}\hat{a}_\kappa\hat{a}_\nu. \tag{9.87}$$

Switching to the number operators, $\hat{n}_s = \hat{a}^\dagger_s\hat{a}_s$, and using the commutation relations $\{\hat{a}^\dagger_{\kappa'},\hat{a}^\dagger_{\nu'}\} = \{\hat{a}^\dagger_{\kappa'},\hat{a}_\nu\} = 0$ (note that $\nu' \neq \kappa'$ and $\nu \neq \kappa'$) we have $\hat{a}^\dagger_{\kappa'}\hat{a}^\dagger_{\nu'}\hat{a}_\nu\hat{a}_\kappa = \hat{a}^\dagger_{\nu'}\hat{a}_\nu\hat{a}^\dagger_{\kappa'}\hat{a}_\kappa$ and $\hat{a}^\dagger_{\kappa'}\hat{a}^\dagger_{\nu'}\hat{a}_\kappa\hat{a}_\nu = -\hat{a}^\dagger_{\nu'}\hat{a}_\nu\hat{a}^\dagger_{\kappa'}\hat{a}_\kappa$ this becomes

$$\langle\psi_{\alpha'}|Q_2|\psi_\alpha\rangle = (-)^{p_\kappa+p_\nu}\left[(\alpha_\kappa,\alpha_\nu|q_{12}|\alpha_\kappa,\alpha_\nu) - (\alpha_\kappa,\alpha_\nu|q_{12}|\alpha_\nu,\alpha_\kappa)\right], \tag{9.88}$$

which coincides with the result (9.49) with p_ν and $p_{\nu'}$ representing the orders of the permutations that bring the states $|\alpha_\nu\rangle$ and $|\alpha_{\kappa'}\rangle$, respectively, to the first column position in the Slater determinant.

- *Off-diagonal matrix elements differing in more than two pairs of states.* In this case we always have

$$\langle\psi_{\alpha'}|\hat{Q}_2|\psi_\alpha\rangle = 0 \tag{9.89}$$

because the operator $\hat{Q}_2$ can annihilate and create at most replace two states.

9.4 Angular momentum of N-electron Slater determinants

9.4.1 Total orbital angular momentum L

Having established a procedure to calculate the matrix elements of one-body and two-body operators for properly symmetrized N-electron basis states $|\psi_\alpha\rangle = |\alpha_1,\cdots,\alpha_N\rangle$, where $|\alpha_\kappa\rangle = |n^\kappa l^\kappa m_l^\kappa s m_s^\kappa\rangle$ with $\kappa \in \{1,\cdots N\}$ and $s = \frac{1}{2}$ being one-electron eigenstates of the spin-orbital type, we are in a position to determine the properties of the total orbital angular momentum operator

$$\mathbf{L} = \sum_{i=1}^{N} \boldsymbol{l}_i \tag{9.90}$$

on the basis $\{|\psi_\alpha\rangle\}$. Obvious questions involve the action of the operators L_z, $L_\pm$ and $\mathbf{L}^2$ on a given many-body basis state $|\psi_\alpha\rangle$. Using the closure relation the action of any operator G can be written in the form of an expansion in the basis functions

$$G|\psi_\alpha\rangle = \sum_{\alpha'} |\psi_{\alpha'}\rangle\langle\psi_{\alpha'}|G|\psi_\alpha\rangle \tag{9.91}$$

and we shall use this relation to investigate L_z, $L_\pm$ and $\mathbf{L}^2$. Importantly, we shall find that Slater determinants are not necessarily eigenstates of the operators $L_\pm$ and $\mathbf{L}^2$.

- *The operator L_z.* The operator $L_z = \sum_i l_z^{(i)}$ is of the diagonal one-body type. It conserves the angular momentum and its projection along the z axis is diagonal in the $\{|\psi_\alpha\rangle\}$ representation. Thus, the expansion (9.91) reduces to a single term

$$L_z|\psi_\alpha\rangle = |\psi_\alpha\rangle\langle\psi_\alpha|L_z|\psi_\alpha\rangle = |\psi_\alpha\rangle \sum_{\kappa=1}^{N} \langle l^\kappa m_l^\kappa|l_z|l^\kappa m_l^\kappa\rangle\langle s m_s^\kappa|s m_s^\kappa\rangle = M_L^\alpha \hbar\,|\psi_\alpha\rangle, \tag{9.92}$$

where we factored out the spin part, $\langle sm_s^\kappa|sm_s^\kappa\rangle = 1$, and where

$$M_L^\alpha = \sum_{\kappa=1}^{N} m_l^\kappa \tag{9.93}$$

is the magnetic quantum number of the total orbital angular momentum of the state $|\psi_\alpha\rangle$.

- *The operator* $L_\pm$. The operator $L_\pm = \sum_i l_\pm^{(i)}$ is of the off-diagonal one-body type. It raises or lowers the m_l^κ of *one* of the electrons of the state $|\psi_\alpha\rangle$ by one unit of angular momentum. Thus, if $\{|\psi_\gamma\rangle\}$ represents the subset (of N elements) of $\{|\psi_{\alpha'}\rangle\}$ for which m_l^κ (and M_L^α) change by one, the expansion (9.91) reduces to

$$\begin{aligned} L_\pm|\psi_\alpha\rangle &= \sum_\gamma |\psi_\gamma\rangle\langle\psi_\gamma|L_\pm|\psi_\alpha\rangle = \sum_{\kappa=1}^{N} |\psi_\alpha(m_l^\kappa \pm 1)\rangle\langle l^\kappa(m_l^\kappa \pm 1)|l_\pm|l^\kappa m_l^\kappa\rangle \\ &= \sum_{\kappa=1}^{N} \sqrt{l^\kappa(l^\kappa+1) - m_l^\kappa(m_l^\kappa \pm 1)}\,\hbar\,|\psi_\alpha(m_l^\kappa \pm 1)\rangle. \end{aligned} \tag{9.94}$$

Again the spin part has been factored out, $\langle sm_s^\kappa|sm_s^\kappa\rangle = 1$. With the notation $|\psi_\gamma\rangle = |\psi_\alpha(m_l^\kappa \pm 1)\rangle$, with $\kappa \in \{1,\cdots N\}$, we mean that the state $|\alpha_\kappa\rangle = |n^\kappa l^\kappa m_l^\kappa s m_s^\kappa\rangle$ has been replaced by $|\alpha'_\kappa\rangle = |n^\kappa l^\kappa(m_l^\kappa \pm 1)sm_s^\kappa\rangle$. With this choice of ordering of the many-body state the phase factor is always unity, $(-1)^{2p} = 1$. The meaning of $|\psi_\alpha(m_l^\kappa \pm 1)\rangle = |\alpha'_\kappa\rangle$ is best expressed in the occupation number representation

$$|\alpha'_\kappa\rangle = \hat{a}^\dagger_{\alpha'_\kappa}\hat{a}_{\alpha_\kappa}|\alpha_\kappa\rangle. \tag{9.95}$$

- *The operator* $\mathbf{L}^2$. This operator $\mathbf{L}^2 = (\sum_i \boldsymbol{l}_i)^2$ can be written in the form

$$\mathbf{L}^2 = \sum_i \boldsymbol{l}_i^2 + \sum_{i,j}{}' \boldsymbol{l}_i \cdot \boldsymbol{l}_j = \sum_i \boldsymbol{l}_i^2 + \frac{1}{2}\sum_{i,j}{}'[2l_z^{(i)}l_z^{(j)} + (l_+^{(i)}l_-^{(j)} + l_-^{(i)}l_+^{(j)})]. \tag{9.96}$$

Since $l_-^{(i)}$ and $l_+^{(j)}$ commute for $i \neq j$ and the indices run over the same set of values, $i, j \in \{1,\cdots N\}$, the expression for $\mathbf{L}^2$ reduces to

$$\mathbf{L}^2 = \sum_i \boldsymbol{l}_i^2 + \sum_{i,j}{}'[l_z^{(i)}l_z^{(j)} + l_+^{(i)}l_-^{(j)}]. \tag{9.97}$$

The first term is of the diagonal one-body type and the second of the diagonal two-body type. The remaining term is of the off-diagonal two-body type with differences in two pairs. In view of the off-diagonality of the $l_+^{(i)}l_-^{(j)}$ operator, the direct terms vanish. Along the same lines as above the action of the operator $\mathbf{L}^2$ is given by

$$\begin{aligned} \mathbf{L}^2|\psi_\alpha\rangle = &\left\{\sum_{\kappa=1}^{N} l^\kappa(l^\kappa+1) + \sum_{\kappa,\kappa'=1}^{N}{}' m_l^\kappa m_l^{\kappa'}\right\}\hbar^2\,|\psi_\alpha\rangle + \\ &+ \sum_{\kappa,\kappa'=1}^{N}{}' \sqrt{l^\kappa(l^\kappa+1) - m_l^\kappa(m_l^\kappa+1)}\sqrt{l^{\kappa'}(l^{\kappa'}+1) - m_l^{\kappa'}(m_l^{\kappa'}-1)}\,\hbar^2\,|\psi_\alpha(m_l^\kappa+1)(m_l^{\kappa'}-1)\rangle, \end{aligned} \tag{9.98}$$

where the notation

$$|\psi_\gamma\rangle = |\psi_\alpha(m_l^\kappa+1)(m_l^{\kappa'}-1)\rangle \equiv |\psi_\alpha(m_l^{\kappa'}-1)(m_l^\kappa+1)\rangle, \tag{9.99}$$

with $\kappa, \kappa' \in \{1, \cdots N\}$, indicates that the state $|\alpha_\kappa\rangle = |n^\kappa l^\kappa m_l^\kappa s m_s^\kappa\rangle$ has been replaced by $|\alpha'_\kappa\rangle = |n^\kappa l^\kappa (m_l^\kappa + 1) s m_s^\kappa\rangle$ and the state $|\alpha_{\kappa'}\rangle = |n^{\kappa'} l^{\kappa'} m_l^{\kappa'} s m_s^{\kappa\prime}\rangle$ by $|\alpha'_{\kappa'}\rangle = |n^{\kappa'} l^{\kappa'} (m_l^{\kappa'} - 1) s m_s^{\kappa'}\rangle$. Note that

$$|\psi_\alpha(m_l^\kappa + 1)(m_l^{\kappa'} - 1)\rangle = -|\psi_\alpha\rangle \quad \text{for } m_l^{\kappa'} - m_l^\kappa = 1. \tag{9.100}$$

The meaning of $|\psi_\alpha(m_l^\kappa + 1)(m_l^{\kappa'} - 1)\rangle$ is best expressed in the occupation number representation

$$|\psi_\alpha(m_l^\kappa + 1)(m_l^{\kappa'} - 1)\rangle = |\alpha'_\kappa, \alpha'_{\kappa'}\rangle = \hat{a}^\dagger_{\alpha'_\kappa} \hat{a}^\dagger_{\alpha'_{\kappa'}} \hat{a}_{\alpha_{\kappa'}} \hat{a}_{\alpha_\kappa} |\alpha_\kappa, \alpha_{\kappa'}\rangle. \tag{9.101}$$

There are $\binom{N}{2}$ different states of this type and these correspond to all different pair combinations of $\kappa, \kappa' \in \{1, \cdots N\}$ with $\kappa \neq \kappa'$. Note that for these states $\langle\psi_\gamma|L_z|\psi_\gamma\rangle = \langle\psi_\alpha|L_z|\psi_\alpha\rangle$. As demonstrated in Problem 9.8 Eq. (9.98) can be strongly simplified for *stretched* states of N equal angular momenta l, where both the total angular momentum and its projection are maximized ($L = M_L = Nl$).

9.4.1.1 Example:

Let us further clarify the notation $|\psi_\alpha(m_l^\kappa + 1)(m_l^{\kappa'} - 1)\rangle$. For the state

$$|\psi_\alpha\rangle = |\alpha_\kappa, \alpha_{\kappa'}\rangle = |m_l^\kappa, m_l^{\kappa'}\rangle_{nd^2} = |\dot{1}, \dot{0}\rangle_{nd^2} \tag{9.102}$$

we have $|\alpha_\kappa\rangle = |n^\kappa l^\kappa m_l^\kappa s m_s^\kappa\rangle = |n, 2, 1, \frac{1}{2}, \frac{1}{2}\rangle$ and $|\alpha_{\kappa'}\rangle = |n^{\kappa'} l^{\kappa'} m_l^{\kappa'} s m_s^{\kappa\prime}\rangle = |n, 2, 0, \frac{1}{2}, \frac{1}{2}\rangle$. The states

$$|\psi_\gamma\rangle = |\psi_\alpha(m_l^\kappa + 1)(m_l^{\kappa'} - 1)\rangle = |\alpha'_\kappa, \alpha'_{\kappa'}\rangle = |\dot{2}, -\dot{1}\rangle_{nd^2} \tag{9.103a}$$

$$|\psi'_\gamma\rangle = |\psi_\alpha(m_l^\kappa - 1)(m_l^{\kappa'} + 1)\rangle = |\alpha'_\kappa, \alpha'_{\kappa'}\rangle = |\dot{0}, \dot{1}\rangle_{nd^2} = -|\dot{1}, \dot{0}\rangle_{nd^2} \tag{9.103b}$$

correspond to, respectively

$$\left.\begin{aligned} |\alpha'_\kappa\rangle &= |n^\kappa l^\kappa (m_l^\kappa + 1) s m_s^\kappa\rangle = |n, 2, 2, \tfrac{1}{2}, \tfrac{1}{2}\rangle \\ |\alpha'_{\kappa'}\rangle &= |n^{\kappa'} l^{\kappa'} (m_l^{\kappa'} - 1) s m_s^{\kappa\prime}\rangle = |n, 2, -1, \tfrac{1}{2}, \tfrac{1}{2}\rangle \end{aligned}\right\} \tag{9.104a}$$

$$\left.\begin{aligned} |\alpha'_\kappa\rangle &= |n^\kappa l^\kappa (m_l^\kappa - 1) s m_s^\kappa\rangle = |n, 2, 0, \tfrac{1}{2}, \tfrac{1}{2}\rangle \\ |\alpha'_{\kappa'}\rangle &= |n^{\kappa'} l^{\kappa'} (m_l^{\kappa'} + 1) s m_s^{\kappa\prime}\rangle = |n, 2, +1, \tfrac{1}{2}, \tfrac{1}{2}\rangle \end{aligned}\right\}. \tag{9.104b}$$

Problem 9.7. Calculate the total orbital angular momentum of the Slater determinant $|\dot{1}, \dot{0}\rangle_{np^2}$.

Solution. For two equivalent electrons we have $N = 2$ and the expression for $\mathbf{L}^2$ becomes

$$\begin{aligned} \mathbf{L}^2 |\dot{1}, \dot{0}\rangle_{np^2} &= \left\{2l(l+1) + 2m_l^{(1)} m_l^{(2)}\right\} \hbar^2 \, |\dot{1}, \dot{0}\rangle_{np^2} \\ &+ \sqrt{l(l+1) - m_l^{(1)}(m_l^{(1)} + 1)} \sqrt{l(l+1) - m_l^{(2)}(m_l^{(2)} - 1)} \, \hbar^2 \, |\psi_\alpha(m_l^{(1)} + 1)(m_l^{(2)} - 1)\rangle \\ &+ \sqrt{l(l+1) - m_l^{(2)}(m_l^{(2)} + 1)} \sqrt{l(l+1) - m_l^{(1)}(m_l^{(1)} - 1)} \, \hbar^2 \, |\psi_\alpha(m_l^{(2)} + 1)(m_l^{(1)} - 1)\rangle \end{aligned}$$

Substituting $l^{(1)} = l^{(2)} = l = 1$, $m_l^{(1)} = 1$ and $m_l^{(2)} = 0$ we calculate $m_l^{(1)} m_l^{(2)} = 0$ and

$$\begin{array}{lll} m_l^{(1)}(m_l^{(1)} + 1) = 2 & m_l^{(2)}(m_l^{(2)} - 1) = 0 & |\psi_\alpha(m_l^{(1)} + 1)(m_l^{(2)} - 1)\rangle = |\dot{2}, -\dot{1}\rangle_{np^2} \\ m_l^{(2)}(m_l^{(2)} + 1) = 0 & m_l^{(1)}(m_l^{(1)} - 1) = 0 & |\psi_\alpha(m_l^{(2)} + 1)(m_l^{(1)} - 1)\rangle = -|\dot{1}, \dot{0}\rangle_{np^2} \end{array}$$

Thus we obtain

$$\mathbf{L}^2 |\dot{1}, \dot{0}\rangle_{np^2} = \{2l(l+1) - 2\}\hbar^2 \, |\dot{1}, \dot{0}\rangle_{np^2} = 2\hbar^2 \, |\dot{1}, \dot{0}\rangle_{np^2}$$

and with $L(L+1) = 2$ we calculate $L = 1$. □

Problem 9.8. Show that eigenstates with $L = M_L = Nl$, i.e. with stretched total orbital angular momentum, can be represented by a single N-body Slater determinant $|\psi_\alpha^{ll}\rangle = |\alpha_1, \cdots, \alpha_N\rangle$ of spin-orbitals $|\alpha_\kappa\rangle = |n^\kappa llsm_s^\kappa\rangle$ with $\kappa \in \{1, \cdots N\}$. For $N > 2$ the spin-orbitals must differ in the quantum numbers n^κ and/or m_s^κ.

Solution. Setting $l^\kappa = m_l^\kappa = l$ in Eq. (9.92) and (9.98) these expression evaluate to

$$\begin{aligned}
&L_z|\psi_\alpha^{ll}\rangle = Nl\hbar\,|\psi_\alpha^{ll}\rangle \\
&\mathbf{L}^2|\psi_\alpha^{ll}\rangle = \left[N\,l(l+1) + N(N-1)l^2\right]\hbar^2|\psi_\alpha^{ll}\rangle = Nl(Nl+1)\hbar^2|\psi_\alpha^{ll}\rangle,
\end{aligned}$$

where $Nl = L = M_L$ and $|\psi_\alpha^{ll}\rangle$ is the Slater determinant we are looking for. Analogous expressions can be derived for stretched spin states. □

9.4.1.2 Commutation relations

Starting from $\mathbf{L} = \sum_{i=1}^N \boldsymbol{l}_i$ and $L_z = \sum_{i=1}^N l_z^{(i)}$ it is straightforward to derive the following commutation relations (see Problems 9.9 and 9.10)

$$[\mathbf{L}^2, \boldsymbol{l}_i^2] = 0 \text{ and } [L_z, \boldsymbol{l}_i^2] = 0 \tag{9.106a}$$

$$[\mathbf{L}^2, l_z^{(i)}] \neq 0 \text{ but } [\mathbf{L}^2, L_z] = 0. \tag{9.106b}$$

Problem 9.9. Prove the commutation relations (9.106b)

$$[\mathbf{L}^2, l_\nu^{(i)}] \neq 0 \text{ but } [\mathbf{L}^2, L_\nu] = 0 \;\text{ for } i \in \{1, \cdots N\} \text{ and } \nu \in \{x, y, z\}.$$

Note that this is a generalization of the commutation relation (4.8).

Solution. Let us choose $\nu = z$ (proof analogous for $\nu \in \{x, y\}$). Using Eq. (9.97) we find

$$\begin{aligned}
[\mathbf{L}^2, l_z^{(i)}] &= \sum_j [\boldsymbol{l}_j^2, l_z^{(i)}] + \sum_{j,k}{}' \left([l_x^{(j)}l_x^{(k)}, l_z^{(i)}] + [l_y^{(j)}l_y^{(k)}, l_z^{(i)}] + [l_z^{(j)}l_z^{(k)}, l_z^{(i)}]\right) \\
&= [\boldsymbol{l}_i^2, l_z^{(i)}] + \sum_j{}' \left(l_x^{(j)}[l_x^{(i)}, l_z^{(i)}] + l_y^{(j)}[l_y^{(i)}, l_z^{(i)}]\right) + \sum_k{}' \left([l_x^{(i)}, l_z^{(i)}]l_x^{(k)} + [l_y^{(i)}, l_z^{(i)}]l_y^{(k)}\right),
\end{aligned}$$

where the prime indicates that $j \neq i \neq k$. Changing dummy index $k \to j$ and using the commutation relation (1.36) this results in [

$$[\mathbf{L}^2, l_z^{(i)}] = 2\sum_j{}' \left(l_x^{(j)}[l_x^{(i)}, l_z^{(i)}] + l_y^{(j)}[l_y^{(i)}, l_z^{(i)}] + l_z^{(j)}[l_z^{(i)}, l_z^{(i)}]\right) = 2\hbar\sum_j{}' \left(-l_x^{(j)}l_y^{(i)} + l_y^{(j)}l_x^{(i)}\right) \neq 0.$$

This shows that $\mathbf{L}^2$ and $l_z^{(i)}$do *not* commute. Summing the $l_z^{(i)}$ to L_z we obtain

$$[\mathbf{L}^2, L_z] = \sum_i [\mathbf{L}^2, l_z^{(i)}] = 2\hbar\sum_{i,j}{}' \left(l_y^{(j)}l_x^{(i)} - l_x^{(j)}l_y^{(i)}\right) = 0$$

because i and j run over the same range of values $i, j \in \{1, \cdots N\}$. □

Problem 9.10. Prove the commutation relations (9.106a)

$$[\mathbf{L}^2, \boldsymbol{l}_i^2] = 0 \text{ and } [L_\nu, \boldsymbol{l}_i^2] = 0 \;\text{ for } i \in \{1, \cdots N\} \text{ and } \nu \in \{x, y, z\}.$$

Note that this is a generalization of the commutation relation (4.7).

Solution. Using Eq. (9.96) we have

$$[\mathbf{L}^2, \boldsymbol{l}_i^2] = \sum_j [\boldsymbol{l}_j^2, \boldsymbol{l}_i^2] + \sum_{j,k}{}' [\boldsymbol{l}_j \cdot \boldsymbol{l}_k, \boldsymbol{l}_i^2]$$

The first term vanishes because $\sum_j[\boldsymbol{l}_j^2,\boldsymbol{l}_i^2]=[\boldsymbol{l}_i^2,\boldsymbol{l}_i^2]=0$. Also the second term is zero because

$$\begin{aligned}\sum_{j,k}{}'[\boldsymbol{l}_j\cdot\boldsymbol{l}_k,\boldsymbol{l}_i^2] &= \sum_{\nu=x,y,z}\sum_{j,k}{}'\left([l_\nu^{(j)},\boldsymbol{l}_i^2]l_\nu^{(k)}+l_\nu^{(j)}[l_\nu^{(k)},\boldsymbol{l}_i^2]\right),\\ &= \sum_{\nu=x,y,z}\sum_{k}{}'[l_\nu^{(i)},\boldsymbol{l}_i^2]l_\nu^{(k)}+\sum_{\nu=x,y,z}\sum_{j}{}'l_\nu^{(j)}[l_\nu^{(i)},\boldsymbol{l}_i^2]=0\end{aligned}$$

because $[l_\nu^{(i)},\boldsymbol{l}_i^2]=0$ for $\nu\in\{x,y,z\}$; the prime indicates that $j\neq i\neq k$. Hence, $\mathbf{L}^2$ and $\boldsymbol{l}_i^2$ indeed commute. In view of the definition of L_ν we have

$$[L_\nu,\boldsymbol{l}_i^2]=\sum_j[l_\nu^{(j)},\boldsymbol{l}_i^2]=[l_\nu^{(i)},\boldsymbol{l}_i^2]=0. \qquad \square$$

9.4.2 Total electronic spin S

The properties of the total spin angular momentum operator

$$\mathbf{S}=\textstyle\sum_i\boldsymbol{s}_i \tag{9.107}$$

acting on the basis $\{|\psi_\alpha\rangle\}$ is rapidly derived from the expressions for the orbital angular momentum derived above. The spin case is somewhat simpler because the spin of the individual electrons is always $s=\frac{1}{2}$ and the magnetic quantum number can only take the values $m_s=\pm1/2$. Thus we obtain

- *The operator* $S_z=\sum_i s_z^{(i)}$. In analogy with Eq. (9.92) we find

  $$S_z|\psi_\alpha\rangle=M_S^\alpha\hbar\,|\psi_\alpha\rangle, \tag{9.108}$$

  where $M_S^\alpha=\sum_\kappa m_s^\kappa$ is the total magnetic quantum number of the state $|\psi_\alpha\rangle$.

- *The operator* $S_\pm=\sum_i s_\pm^{(i)}$. In analogy with Eq. (9.94) we find

  $$S_\pm|\psi_\alpha\rangle=\sum_\kappa\sqrt{s(s+1)-m_s^\kappa(m_s^\kappa\pm1)}\,\hbar\,|\psi_\alpha(m_s^\kappa\pm1)\rangle. \tag{9.109}$$

- *The operator* $\mathbf{S}^2=(\sum_i\boldsymbol{s}_i)^2$. In analogy with Eq. (9.98) we find

$$\begin{aligned}\mathbf{S}^2|\psi_\alpha\rangle &= \left\{\sum_\kappa s(s+1)+\sum_{\kappa,\kappa'}{}'m_s^\kappa m_s^{\kappa'}\right\}\hbar^2\,|\psi_\alpha\rangle+\\ &\quad+\sum_{\kappa,\kappa'}{}'\sqrt{s(s+1)-m_s^\kappa(m_s^\kappa+1)}\sqrt{s(s+1)-m_s^{\kappa'}(m_s^{\kappa'}-1)}\,\hbar^2\,|\psi_\alpha(m_s^\kappa+1)(m_s^{\kappa'}-1)\rangle.\end{aligned} \tag{9.110}$$

9.4.2.1 Commutation relations

Analogous to the commutation relations for the orbital angular momentum it is straightforward to derive the following commutation relations for the total electronic spin

$$[\mathbf{S}^2,\boldsymbol{s}_i^2]=0 \quad \text{and} \quad [S_z,\boldsymbol{s}_i^2]=0; \quad [\mathbf{S}^2,s_z^{(i)}]\neq0 \quad \text{but} \quad [\mathbf{S}^2,S_z]=0. \tag{9.111}$$

9.4.3 Total electronic angular momentum J

To conclude this chapter we also consider the total electronic angular momentum,

$$\mathbf{J} = \textstyle\sum_i (\boldsymbol{l}_i + \boldsymbol{s}_i). \tag{9.112}$$

Since $\mathbf{J} = \mathbf{L} + \mathbf{S}$ we can derive the following commutation relations,

$$[\mathbf{J}^2, \boldsymbol{l}_i^2] = 0 \text{ and } [J_z, \boldsymbol{l}_i^2] = 0. \tag{9.113}$$

Problem 9.11. Prove the commutation relations (9.113)

$$[\mathbf{J}^2, \boldsymbol{l}_i^2] = 0 \text{ and } [J_z, \boldsymbol{l}_i^2] = 0 \quad \text{for } i \in \{1, \cdots N\}.$$

Solution. Using the first commutation relation (9.106a) we obtain

$$[\mathbf{J}^2, \boldsymbol{l}_i^2] = [\mathbf{L}^2 + \mathbf{S}^2 + \mathbf{L}\cdot\mathbf{S}, \boldsymbol{l}_i^2] = [\mathbf{L}\cdot\mathbf{S}, \boldsymbol{l}_i^2]$$

and using the second commutation relation (9.106a) we find

$$\begin{aligned}[\mathbf{L}\cdot\mathbf{S}, \boldsymbol{l}_i^2] &= [L_x S_x + L_y S_y + L_z S_z), \boldsymbol{l}_i^2] \\ &= [L_x, \boldsymbol{l}_i^2] S_x + [L_y, \boldsymbol{l}_i^2] S_y + [L_z, \boldsymbol{l}_i^2] S_z = 0.\end{aligned}$$

□

10

Ground states of many-electron atoms

The structure of the electronic ground state of all atomic elements can be predicted by a set of rules, commonly referred to under the name *Aufbau* principle and first formulated by Niels Bohr in the beginning of the 1920's [20]. It was known since the work of Dmitry Mendeleev in 1869 that the elements can be grouped systematically in order of growing nuclear charge (Z) in the form of a periodic table [72]. The Aufbau principle explains the periodic structure of the table and provides us with the electron configuration of the atomic ground state as well as with the angular momentum properties of the elements. The interpretation of the table evolved over the years but its periodic structure remained a defining feature. As shown in Table A.1 the elements are collected in seven *periods* (rows) subdivided in *groups* (columns). The periods correspond to shells of electrons with the period number defining the principal quantum number of the least bound s shell. Within a period, the group number reflects the filling of the shells. For instance, the $1s^2$ configuration of the helium ground state consists of two equivalent s electrons with $m_l = 0$ and $m_s = \pm\frac{1}{2}$ and represents the fully filled $1s$ shell. Likewise, the $1s^2 2s^2 2p^6$ configuration of the neon ground state consists of closed shells, with two equivalent s electrons in the $1s$ and the $2s$ shells with $m_l = 0$ and $m_s = \pm\frac{1}{2}$ and six equivalent p electrons in the $2p$ shell with $m_l = 0, \pm 1$ and $m_s = \pm\frac{1}{2}$. One distinguishes between short periods (group I through VIII), long periods (group 1 through 18, which include 10 groups of *transition elements*) and extra-long periods (which include an additional 14 groups of *rare-earth elements* - *lanthanides* and *actinides*).[1] The transition elements involve filling of the d shells and the rare-earth elements filling of the f shells.

Together, the shells of equivalent electrons provide the *atomic shell structure* of the atom, which is the backbone of the Aufbau principle. In X-ray spectroscopy one uses the shell notation $K, L, M, \cdots$ for the principal quantum numbers $n = 1, 2, 3, \cdots$. The rotational substructure is represented by an index; e.g., L_1, L_2, L_3. Although this notation is valuable for the innermost shells it is not practical for the outer shells of large atoms. In the latter case shells of different n can have similar binding energy. Therefore, we shall refer to shells by specifying always both n and l. When n and l no longer represent good quantum numbers the picture of a single relevant electron configuration breaks down. This happens when two configurations are approximately degenerate and a mixed configuration results in stronger binding. This being said, for most elements, a single electron configuration is a good starting point.

In ground state atoms the *closed shells* form a spherically symmetric *core* of electrons surrounded by typically one or two incomplete shells of *valence* electrons. In Section 4.6 we found that the core gives rise to substantial screening of the nuclear charge, in such a way that at large distance the valence electrons behave similar to the electrons of one-, two-, three-,$\cdots$ electron atoms with a singly-, doubly-, triply-,$\cdots$ charged nucleus, respectively. The success of describing atoms in terms of electron configurations points to the presence of a mostly *central* effective field similar to the

---

[1] The *rare-earth elements* are often referred to with the plural *rare earths*. Strictly speaking this term is reserved for the oxides of these elements.

Hartree self-consistent field introduced in Section 8.5. The Pauli principle and exchange phenomena can be incorporated into the Hartree method by representing the electron configuration by a Slater determinant. This is known as the Hartree-Fock approach (Section 10.2).

10.1 Aufbau principle and Hund's rules

The *valence electrons* are of special importance for the Aufbau principle because their configuration determines the atomic ground state. The name *valence* points to the number of electrons participating in *chemical bonding*. This context also explains the names *donor* shell (for shells with less than half filling) and *acceptor* shell (for shells with more than half filling). As the binding energy of the valence electrons increases with shell filling, closed shells are least favorable for chemical bonding. Almost filled shells carry the angular momentum of the vacant electron(s). Such vacancies behave like electrons of positive charge and negative mass and are referred to as *holes* in the closed shell. Neglecting spin-orbit coupling, we can use the angular momentum addition rules to determine all possible values of the total orbital angular momentum and the total spin of a given electron configuration,

$$\mathbf{L} = \sum_i \boldsymbol{l}_i \ \text{ and } \ \mathbf{S} = \sum_i \boldsymbol{s}_i. \tag{10.1}$$

Thus we identify one or more so called LS terms, each consisting of $(2L+1)(2S+1)$ *degenerate* energy levels sharing the quantum numbers L and S. The energy of the LS terms depends on the electrostatic repulsion between the spinorbitals. For this reason we speak of *electrostatic coupling* of the single-electron orbital angular momenta $\{\boldsymbol{l}_i\}$ and of the single-electron spins $\{\boldsymbol{s}_i\}$ into states of well-defined L and S.

Closed shells can be represented by a single non-degenerate LS term ($L = 0$, $S = 0$). This means that only the valence electrons determine the atomic angular momentum; i.e., the valence electrons suffice to determine the LS term of the electronic ground state. The latter can be established by a sequence of three semi-empirical rules of thumb, the *Hund rules*, for which we shall establish the physical underpinning. The first two Hund rules are designed to select the LS term with smallest electrostatic repulsion between the spinorbitals:

Rule 1 Choose the maximum value of S consistent with the Pauli principle
Rule 2 Choose the maximum value of L consistent with the Pauli principle.

For a given LS term we can still have several possible values of the total electronic angular momentum J, which is the conserved quantity of the electron cloud (neglecting the hyperfine interaction with the nuclear spin) and ranges in integer steps from $|L-S|$ to $L+S$, thus adding up to the above mentioned $(2L+1)(2S+1)$ degenerate levels. The third Hund rule discriminates between these values:

$$\textit{Rule 3} \ \text{ Choose } J = \begin{cases} J_{\min} = |L-S| \text{ for shells } \textit{less} \text{ than half-filled} \\ J_{\max} = L+S \ \text{ for shells } \textit{more} \text{ than half-filled.} \end{cases}$$

To appreciate the third Hund rule we have to understand how the degeneracy of the LS terms is lifted by the spin-orbit interaction. In one-electron atoms this originates in the velocity-induced coupling of the spin $\boldsymbol{s}$ of the electron with its own orbital angular momentum $\boldsymbol{l}$ into the total electronic angular momentum $\boldsymbol{j}$. In many-electron atoms we have to deal with competition between the electrostatic coupling and the spin-orbit coupling. This gives rise to different coupling schemes depending on Z.

10.2 Hartree-Fock method

10.2.1 Hamiltonian

The Hund rules offer a simple procedure to predict the electronic ground state of the elements, at least in most cases. Therefore, it is important for our understanding of the periodic system to be aware of the general principles behind these rules. To identify these principles we shall introduce the Hartree-Fock method, which is a self-consistent field method that captures most of the physics determining the atomic ground state. It differs from the Hartree method because it accounts for exchange. It also provides insight in the limitations of the Hund rules.

We start from the Hartree Hamiltonian (8.42) for N electrons with mutual repulsion and moving in the electrostatic field of the nucleus of charge Ze,

$$\mathcal{H}=\sum_{i=1}^{N}h_0^{(i)}+\tfrac{1}{2}\sum_{i,j=1}^{N}{}'\frac{1}{\rho_{ij}}. \tag{10.2}$$

We recall from Chapters 7 and 8 that the repulsion term can be interpreted as giving rise to a mostly centrally symmetric screening potential about the nucleus. Following up on this result we start the discussion by simply presuming that also in the present case central symmetry dominates the motion of the individual electrons. This enables us to use separation of variables, which implies that the individual electrons occupy spinorbitals of well-defined angular momentum (just as in the hydrogenic wavefunctions). Importantly, $\mathcal{H}$ is invariant under rotation of the spatial coordinates about the origin. Therefore, the *total* orbital angular momentum ($\mathbf{L}$) is a conserved quantity (i.e., L and M_L are good quantum numbers - see also Problem 7.1). Moreover, as $\mathcal{H}$ is spin independent, also the total spin ($\mathbf{S}$) is conserved and S and M_S are good quantum numbers. In other words, the Hamiltonian $\mathcal{H}$ is diagonal in the $|LM_L,SM_S\rangle$ representation. Later we shall analyze how the spin-orbit interaction breaks this symmetry.

Knowing the number of electrons we use the periodic system to guess the electron configuration. To assure orthogonality of the single-electron wavefunctions the N-electron state $|\psi_\alpha\rangle$ is constructed in the form of a Slater determinant

$$|\psi_\alpha\rangle=|\alpha_1,\cdots\alpha_N\rangle \tag{10.3}$$

of one-electron spinorbitals

$$|\alpha_\kappa\rangle=|n^\kappa l^\kappa m_l^\kappa s m_s^\kappa\rangle=|u_\kappa\rangle\otimes|sm_s^\kappa\rangle, \tag{10.4}$$

with $\kappa\in\{1,\cdots N\}$ being the *state index*. As the electron configuration of partially filled shells leaves freedom in choosing the magnetic quantum numbers m_l and m_s usually several Slater determinants qualify for our purpose and the ground state will generally be a linear combination of those.

The Hartree-Fock method is a mean-field method in which *a single* Slater determinant of spin orbitals, $|\psi_\alpha\rangle$, is used as a variational trial function to search for the electronic ground-state energy of many-electron atoms [102, 43]. In Hartree atomic units the energy of the state $|\psi_\alpha\rangle$ is given by

$$\varepsilon=\varepsilon(\alpha_1,\cdots\alpha_N)=\langle\psi_\alpha|\mathcal{H}|\psi_\alpha\rangle=\sum_{i=1}^{N}\langle\psi_\alpha|h_0^{(i)}|\psi_\alpha\rangle+\tfrac{1}{2}\sum_{i,j=1}^{N}{}'\langle\psi_\alpha|\frac{1}{\rho_{ij}}|\psi_\alpha\rangle. \tag{10.5}$$

This expression is valid to first order in perturbation theory. The Schrödinger Hamiltonians $h_0^{(i)}$ in the first summation are operators of the one-body diagonal type and the Coulomb repulsions $1/\rho_{ij}$ in the second summation are of the two-body type. To first order in perturbation theory we are only interested in the diagonal matrix elements of the latter. Thus, it follows with the aid of Eqs. (9.44) and (9.52) that the energy of the state $|\psi_\alpha\rangle$ can be written as summations over the state indices,

$$\varepsilon=\sum_{\kappa=1}^{N}\langle u_\kappa|h_0|u_\kappa\rangle+\tfrac{1}{2}\sum_{\kappa,\nu=1}^{N}{}'\left[(u_\kappa,u_\nu|\frac{1}{\rho_{12}}|u_\kappa,u_\nu)-(u_\kappa,u_\nu|\frac{1}{\rho_{12}}|u_\nu,u_\kappa)\,\delta_{m_s^\kappa,m_s^\nu}\right]. \tag{10.6}$$

Note that the spinorbitals are separated in their spin and orbital parts, $|\alpha_\kappa\rangle = |u_\kappa\rangle \otimes |sm_s^\kappa\rangle$. The last term of Eq. (10.6) is the exchange term and shows that the Coulomb repulsion is reduced for electrons in the same spin state because these cannot be at the same position; they avoid close proximity as a result of the quantum correlations of Fermi-Dirac statistics.

10.2.2 Configuration mixing

Importantly, the Coulomb repulsions $1/\rho_{ij}$ can also couple the Slater determinant $|\psi_\alpha\rangle$ of the configuration α to Slater determinants $|\psi_\beta\rangle$ of the configurations β as long as these configurations differ in not more than two spinorbitals. Thus, the configurations become coupled in accordance with Eq. (H.28) of second-order time-independent perturbation theory,

$$|\psi_n\rangle \simeq |\psi_\alpha\rangle + \sum_\beta{}' |\phi_\beta\rangle \frac{\langle\psi_\beta|\frac{1}{2}\sum_{i,j}' \rho_{ij}^{-1}\,|\psi_\alpha\rangle}{E_\alpha^0 - E_\beta^0}. \tag{10.7}$$

Fortunately, in many cases the configuration energies E_α^0 and E_β^0 differ sufficiently to render the second-order admixture negligible. Therefore we shall restrict the discussion to first order.

10.2.3 Hartree-Fock equations

To best approximate the energy of the ground state we search for the set $\{\alpha_\kappa\}$ of N spinorbitals that minimize $\langle\psi_\alpha|\mathcal{H}|\psi_\alpha\rangle$ under the constraints $\langle\alpha_\kappa|\alpha_\kappa\rangle = 1$ and $\langle\alpha_\kappa|\alpha_\nu\rangle = 0$ for $\kappa \neq \nu$; i.e., in addition to the conservation of normalization (as required for the Hartree equations) we also enforce the orthogonality of all orbitals in order to maintain the structure of the Slater determinants [102, 43]. For this purpose we consider the energy $\varepsilon(\alpha_1, \cdots \alpha_N)$, see Eqs. (10.5) and (10.6), as a functional of the spinorbitals $\alpha_1, \cdots \alpha_N$. In particular, for the spinorbital α_κ the functional dependence on the other spinorbitals (α_ν, with $\nu \neq \kappa$) is given by

$$H_\kappa(\alpha_1, \cdots \alpha_N) \equiv \langle u_\kappa|h_0|u_\kappa\rangle + \sum_{\nu=1}^{N}{}' \left[(u_\kappa, u_\nu|\frac{1}{\rho_{12}}|u_\kappa, u_\nu) - (u_\kappa, u_\nu|\frac{1}{\rho_{12}}|u_\nu, u_\kappa)\,\delta_{m_s^\kappa, m_s^\nu} \right], \tag{10.8}$$

where the prime indicates $\nu \neq \kappa$. Repeating the procedure of Section 8.5 the double summation in Eq. (10.6) has been reduced to a single summation Eq. (10.8) and the factor 1/2 disappears; i.e., we sum over all *pairs of orbitals* involving one electron in the spinorbital $|\alpha_\kappa\rangle$. The result is the sum of the unscreened *one-electron* contribution plus the *pair* contribution of the Coulomb interaction between the electron in state $|\alpha_\kappa\rangle$ and all other electrons while taking into account the exchange correlations. Note that the latter only play a role for $m_s^\kappa = m_s^\nu$; i.e., among electrons in the same spin state (cf. Problem 9.5).

To optimize the state $|u_\kappa\rangle$ we construct the lagrangian for the variation of $H_\kappa(\alpha_1, \cdots \alpha_N)$ under the constraints $\langle\alpha_\kappa|\alpha_\kappa\rangle = \langle u_\kappa|u_\kappa\rangle = 1$ and $\langle\alpha_\nu|\alpha_\kappa\rangle = \langle u_\nu|u_\kappa\rangle\langle m_s^\nu|m_s^\kappa\rangle = 0$, where $u_\nu, u_\kappa \in \{u_1, \cdots u_N\}$,

$$\mathcal{L}_\kappa(\alpha_1, \cdots \alpha_N, \lambda_{\kappa 1}, \cdots \lambda_{\kappa N}) = H_\kappa(\alpha_1, \cdots \alpha_N) + \sum_\nu \lambda_{\kappa\nu} \left[\langle u_\nu|u_\kappa\rangle\langle m_s^\nu|m_s^\kappa\rangle - \delta_{\nu,\kappa}\right]. \tag{10.9}$$

Here $\lambda_{\kappa\kappa}$ is the Lagrange multiplier for the normalization constraint $\langle u_\kappa|u_\kappa\rangle = 1$ and $\lambda_{\nu\kappa}$, with $\nu \neq \kappa$, is the Lagrange multiplier for the orthogonality constraint $\langle u_\nu|u_\kappa\rangle\langle m_s^\nu|m_s^\kappa\rangle = 0$. Furthermore, comparing Eq. (10.9) with its hermitian conjugate we find that $\lambda_{\nu\kappa} = \lambda_{\kappa\nu}^*$, which means that the matrix $(\lambda_{\nu\kappa})$ is hermitian. Applying the procedure of Appendix I.1.3 it suffices to minimize the lagrangian (10.9) with respect to $\langle u_\kappa|$,

$$\begin{aligned}\delta\mathcal{L}_\kappa = \langle\delta u_\kappa|h_0|u_\kappa\rangle \\ + \sum_\nu{}' \left[(\delta u_\kappa, u_\nu|\frac{1}{\rho_{12}}|u_\kappa, u_\nu) - (\delta u_\kappa, u_\nu|\frac{1}{\rho_{12}}|u_\nu, u_\kappa)\,\delta_{m_s^\kappa, m_s^\nu}\right] \\ + \sum_\nu \lambda_{\kappa\nu}[\langle\delta u_\nu|u_\kappa\rangle\langle m_s^\nu|m_s^\kappa\rangle - \delta_{\nu,\kappa}].\end{aligned} \quad (10.10)$$

With this procedure the orbital u_κ is found as the solution of a set of N coupled integro-differential equations, the *Hartree-Fock equations*,

$$h_0 u_\kappa(\boldsymbol{\rho}_1) + \sum_\nu{}' \left[\langle u_\nu|\frac{1}{\rho_{12}}|u_\nu\rangle u_\kappa(\boldsymbol{\rho}_1) - \langle u_\nu|\frac{1}{\rho_{12}}|u_\kappa\rangle\,\delta_{m_s^\kappa, m_s^\nu}\, u_\nu(\boldsymbol{\rho}_1)\right] = -\sum_\nu \lambda_{\nu\kappa}\langle m_s^\nu|m_s^\kappa\rangle\, u_\kappa(\boldsymbol{\rho}_1). \quad (10.11)$$

Just like the Hartree equations, the Hartree-Fock equations have to be solved iteratively until self-consistency is reached between the orbitals u_κ and their screening potentials. The solution is not unique because the determinant $|\psi_\alpha\rangle = |\alpha_1, \cdots \alpha_N\rangle$ is invariant under a unitary transformation U of the spinorbitals (see Problem 9.4). This freedom can be exploited to diagonalize the matrix $(\lambda_{\kappa\nu})$, which is always possible because it is hermitian. If we suppose that this goal is realized by the operator $\tilde{U}$ and results in the states $|\tilde{u}_\kappa\rangle = \tilde{U}|u_\kappa\rangle$, with $\kappa \in \{1, \cdots N\}$, Eq. (10.11) is replaced by

$$h_0 \tilde{u}_\kappa(\boldsymbol{\rho}_1) + \sum_\nu{}' \left[\langle \tilde{u}_\nu|\frac{1}{\rho_{12}}|\tilde{u}_\nu\rangle \tilde{u}_\kappa(\boldsymbol{\rho}_1) - \langle \tilde{u}_\nu|\frac{1}{\rho_{12}}|\tilde{u}_\kappa\rangle\,\delta_{m_s^\kappa, m_s^\nu}\, \tilde{u}_\nu(\boldsymbol{\rho}_1)\right] = \varepsilon_\kappa \tilde{u}_\kappa(\boldsymbol{\rho}_1), \quad (10.12)$$

where we defined $\varepsilon_\kappa \equiv -\lambda_\kappa$. Since $\langle\tilde{u}_\nu|\rho_{12}^{-1}|\tilde{u}_\nu\rangle = \langle u_\nu|\rho_{12}^{-1}|u_\nu\rangle$ this set of equations reduces to the Hartree equations (8.63) by omitting the exchange terms. Since we can drop the tilde in Eqs. (10.12) we shall continue from this point on (without loss of generality) by using the symbol u_κ also for the diagonalized equations. In hindsight we come to the conclusion that the orthogonality condition is not an intrinsic requirement of the Hartree-Fock method but could have been omitted by a clever choice of basis in the first place.

The total energy $\varepsilon(\alpha_1, \cdots \alpha_N)$ is stationary if the functionals $H_\kappa(\alpha_1, \cdots \alpha_N)$ are simultaneously stationary under variation of the u_κ. The *optimized* values are denoted by

$$\varepsilon = \varepsilon(\alpha_1, \cdots \alpha_N)|_{\mathrm{opt}} \quad \text{and} \quad \varepsilon_\kappa = H_\kappa(\alpha_1, \cdots \alpha_N)|_{\mathrm{opt}}. \quad (10.13)$$

Importantly, the total energy is *not* simply the sum of the $H_\kappa(\alpha_1, \cdots \alpha_N)|_{\mathrm{opt}}$,

$$\varepsilon \neq \sum_{\kappa=1}^N \varepsilon_\kappa = \sum_{\kappa=1}^N \langle u_\kappa|h_0|u_\kappa\rangle + \sum_{\kappa,\nu=1}^N{}' \left[(u_\kappa, u_\nu|\frac{1}{\rho_{12}}|u_\kappa, u_\nu) - (u_\kappa, u_\nu|\frac{1}{\rho_{12}}|u_\nu, u_\kappa)\,\delta_{m_s^\kappa, m_s^\nu}\right], \quad (10.14)$$

because this would amount to double counting of the interactions. Hence, the proper expression is obtained by subtracting the interaction energy,

$$\varepsilon = \sum_{\kappa=1}^N \varepsilon_\kappa - \tfrac{1}{2}\sum_{\kappa,\nu=1}^N{}' \left[\mathcal{J}(u_\kappa, u_\nu) - \mathcal{K}(u_\kappa, u_\nu)\,\delta_{m_s^\kappa, m_s^\nu}\right]. \quad (10.15)$$

In this notation, the optimized form of Eq. (10.8) becomes

$$\varepsilon_\kappa = \langle u_\kappa|h_0|u_\kappa\rangle + \sum_{\nu=1}^N{}' \left[\mathcal{J}(u_\kappa, u_\nu) - \mathcal{K}(u_\kappa, u_\nu)\,\delta_{m_s^\kappa, m_s^\nu}\right]. \quad (10.16)$$

Substituting this expression into (10.15) we regain the form of Eq. (10.6) for the total energy,

$$\varepsilon = \sum_{\kappa=1}^{N} \langle u_\kappa | h_0 | u_\kappa \rangle + \tfrac{1}{2} {\sum_{\kappa,\nu=1}^{N}}{}' \left[\mathcal{J}(u_\kappa, u_\nu) - \mathcal{K}(u_\kappa, u_\nu)\, \delta_{m_s^\kappa, m_s^\nu} \right], \tag{10.17}$$

but with the hydrogenic states replaced by Hartree-Fock-optimized orbitals. Recalling Problem 7.9 we know that (for equivalent electrons) the exchange integral is positive definite, $\mathcal{K}(u_\kappa, u_\nu) > 0$. Therefore, the energy is minimal if S is maximized, just as phrased in Hund's first rule. Phenomenologically the exchange terms manifest themselves as a strong interaction that tends to align the spins. This is called *ferromagnetic exchange.* It is much stronger than typical magnetic interactions as it originates from spin-dependent differences in electrostatic screening of the nuclear charge.

10.2.4 Koopmans' theorem

The energy ε_κ of an electron in the spinorbital $|\alpha_\kappa\rangle$ of a many-electron atom represents the total energy of this electron when taking into account the Coulomb field of the nucleus and the screening by all other electrons of the atom (in the mean field approximation). Note that this is the energy for *instant* removal of an electron from this state. This is equal to the *ionization* energy of the electron under the conjecture that rearrangement of the remaining charge (during removal of the electron) may be neglected,

$$\varepsilon_\kappa = (\varepsilon_{\text{atom}} - \varepsilon_{\text{ion}}) + \cdots . \tag{10.18}$$

This relation is known as *Koopmans' theorem* [65]. The theorem is best satisfied for ionization of inner core electrons in large atoms.

Koopmans' theorem is important because it enables a comparison between Hartree-Fock theory and experiment. To obtain the theorem in a more formal way we consider the total energy ε_N of an N-electron atom. The energy of the ion created by removal of one electron is denoted by ε_{N-1}. We presume the central field approximation to be well justified in both cases. In the Hartree-Fock approximation the energies of atom and ion can be expressed, respectively, as

$$\varepsilon_N = \sum_{\mu=1}^{N} \langle u_\mu | h_0 | u_\mu \rangle + \tfrac{1}{2} {\sum_{\mu,\nu=1}^{N}}{}' \left[\mathcal{J}(u_\mu, u_\nu) - \mathcal{K}(u_\mu, u_\nu) \delta_{m_s^\mu, m_s^\nu} \right] \tag{10.19}$$

$$\varepsilon_{N-1} = \sum_{\mu=1}^{N-1} \langle u_\mu | h_0 | u_\mu \rangle + \tfrac{1}{2} {\sum_{\mu,\nu=1}^{N-1}}{}' \left[\mathcal{J}(u_\mu, u_\nu) - \mathcal{K}(u_\mu, u_\nu) \delta_{m_s^\mu, m_s^\nu} \right]. \tag{10.20}$$

In this notation it is the electron in state $|u_N\rangle$ that is removed. Subtracting the two expressions we obtain

$$\begin{aligned} \varepsilon_N - \varepsilon_{N-1} = \langle u_N | h_0 | u_N \rangle &+ \tfrac{1}{2} \sum_{\nu=1}^{N-1} \left[\mathcal{J}(u_N, u_\nu) - \mathcal{K}(u_N, u_\nu) \delta_{m_s^N, m_s^\nu} \right] \\ &+ \tfrac{1}{2} \sum_{\mu=1}^{N-1} \left[\mathcal{J}(u_\mu, u_N) - \mathcal{K}(u_\mu, u_N) \delta_{m_s^N, m_s^\nu} \right]. \end{aligned} \tag{10.21}$$

This result is obtained without loss of generality because any of the occupied orbitals $|u_\kappa\rangle$, with $\kappa \in \{1, \cdots N\}$, can be labeled $|u_N\rangle$. However, in writing these expressions we assume that the Coulomb integrals between two orbitals u_μ and u_ν are not affected by the removal of an electron from the orbital u_κ. This is known as the frozen *frozen orbital* approximation. It is only partially satisfied because the removal affects the nuclear screening for all other electrons and therefore the radial distributions of their orbitals. Using the properties of the Coulomb integrals the difference becomes - see Eq. (7.47)

$$\varepsilon_N - \varepsilon_{N-1} = \langle u_\kappa | h_0 | u_\kappa \rangle + \sum_{\nu=1}^{N-1} \left[\mathcal{J}(u_\kappa, u_\nu) - \mathcal{K}(u_\kappa, u_\nu) \delta_{m_s^N, m_s^\nu} \right] = \varepsilon_\kappa, \tag{10.22}$$

which confirms the theorem for the case of instant removal.

10.2.5 Fock operators - direct and exchange contributions

The notation of the Hartree-Fock equations can be simplified to the form

$$\left[-\tfrac{1}{2}\boldsymbol{\nabla}^2 - \frac{Z}{\rho} + J_\kappa(\rho) - K_\kappa(\rho) \right] u_\kappa(\boldsymbol{\rho}) = \varepsilon_\kappa u_\kappa(\boldsymbol{\rho}). \tag{10.23}$$

With this expression we regained the familiar form of the Hartree equations but have the advantage that the Pauli principle is implicitly satisfied. The expression has the appearance of a set of Schrödinger equations for electrons in the orbitals u_κ but formally this is not the case because the operators are *not* one-electron Hamiltonians but give rise to coupling between the equations. By comparison with Eq. (10.12) we find that the operators $J_\kappa(\rho)$ and $K_\kappa(\rho)$ are defined by the expressions

$$J_\kappa(\rho)|u_\kappa\rangle = |u_\kappa\rangle \sum_\nu{}' \langle u_\nu | \frac{1}{\rho_{12}} | u_\nu \rangle \tag{10.24a}$$

$$K_\kappa(\rho)|u_\kappa\rangle = \sum_\nu{}' |u_\nu\rangle \langle u_\nu | \frac{1}{\rho_{12}} | u_\kappa \rangle \delta_{m_s^\kappa, m_s^\nu}. \tag{10.24b}$$

The operators $J_\kappa(\rho)$ and $K_\kappa(\rho)$ represent effective operators for, respectively, the direct and exchange contributions to the Coulomb repulsion energy of an electron in the orbital u_κ. Importantly, only electrons in the same spin state as the electron under consideration contribute to the exchange. In Dirac notation the Hartree-Fock equations takes the form

$$F_\kappa |u_\kappa\rangle = \varepsilon_\kappa |u_\kappa\rangle, \tag{10.25}$$

where $F_\kappa \equiv h_0 + J_\kappa(\rho) - K_\kappa(\rho)$. The operators F_κ are called *Fock operators*. Their expectation value, $\varepsilon_\kappa = \langle u_\kappa | F_\kappa | u_\kappa \rangle$, is given by Eq. (10.16).

Hartree-Fock-Slater approximation

Slater discovered an approximation of the Hartree-Fock method that is particularly valuable to gain physical insight in the meaning of the exchange terms [103]. For two electrons in the same state ($\kappa = \nu$) the difference of the direct and the exchange terms vanishes,

$$(u_\kappa, u_\nu | \frac{1}{\rho_{12}} | u_\kappa, u_\nu) - (u_\kappa, u_\nu | \frac{1}{\rho_{12}} | u_\nu, u_\kappa)\, \delta_{m_s^\kappa, m_s^\nu} = 0 \quad \text{for } \kappa = \nu. \tag{10.26}$$

This has the interesting consequence that we can drop the prime in the derivation of the Hartree-Fock equations as the omitted term yields zero anyhow. In the position representation Eqs. (10.24) become

$$J_\kappa(\rho) u_\kappa(\boldsymbol{\rho}_1) = u_\kappa(\boldsymbol{\rho}_1) \sum_\nu \langle u_\nu | \frac{1}{\rho_{12}} | u_\nu \rangle = u_\kappa(\boldsymbol{\rho}_1) U_D(\boldsymbol{\rho}_1) \tag{10.27a}$$

$$K_\kappa(\rho) u_\kappa(\boldsymbol{\rho}_1) = \sum_\nu u_\nu(\boldsymbol{\rho}_1) \langle u_\nu | \frac{1}{\rho_{12}} | u_\kappa \rangle \delta_{m_s^\kappa, m_s^\nu} = u_\kappa(\boldsymbol{\rho}_1) U_X(\boldsymbol{\rho}_1). \tag{10.27b}$$

where $U_D(\boldsymbol{\rho}_1)$ represents an effective interaction potential, called the *direct screening potential*,

$$U_D(\boldsymbol{\rho}_1) = \sum_{\nu} \int \frac{1}{\rho_{12}} u_{\nu}^*(\boldsymbol{\rho}_2) u_{\nu}(\boldsymbol{\rho}_2) d\boldsymbol{\rho}_2 \tag{10.28}$$

and $U_X(\boldsymbol{\rho})$ is another effective interaction potential, known as the *exchange interaction*

$$U_X(\boldsymbol{\rho}_1) = \sum_{\nu} \delta_{m_s^{\kappa}, m_s^{\nu}} \frac{u_{\kappa}^*(\boldsymbol{\rho}_1) u_{\nu}(\boldsymbol{\rho}_1)}{|u_{\kappa}(\boldsymbol{\rho}_1)|^2} \int \frac{1}{\rho_{12}} u_{\nu}^*(\boldsymbol{\rho}_2) u_{\kappa}(\boldsymbol{\rho}_2) d\boldsymbol{\rho}_2. \tag{10.29}$$

In terms of these potentials the Hartree-Fock equations turn into the *Hartree-Fock-Slater equations*,

$$\left[-\tfrac{1}{2} \boldsymbol{\nabla}^2 - \frac{Z}{\rho} + U_D(\boldsymbol{\rho}) - U_X(\boldsymbol{\rho}) \right] u_{\kappa}(\boldsymbol{\rho}) = \varepsilon_{\kappa} u_{\kappa}(\boldsymbol{\rho}), \tag{10.30}$$

where both $U_D(\boldsymbol{\rho})$ and $U_X(\boldsymbol{\rho})$ vanish at large distance from the nucleus. With this expression we regained the familiar form of the Hartree equations but with the advantage that the Pauli principle is implicitly satisfied.

To elucidate the significance of the effective energy potentials $U_D(\boldsymbol{\rho})$ and $U_X(\boldsymbol{\rho})$ we start by noting that the number density of electrons at position $\mathbf{r}$ is obtained by summing over the probability densities of all occupied orbitals at position $\mathbf{r}$,

$$n(\mathbf{r}) = \sum_{\nu} |u_{\nu}(\mathbf{r})|^2. \tag{10.31}$$

This is the *total electron density* at position $\mathbf{r}$. Integrating over this distribution we obtain the total number of electrons, $\int n(\mathbf{r}) d\mathbf{r} = N$. Thus, the *direct* contribution to the potential energy of an electronic charge at position $\boldsymbol{\rho}_1$ in the Coulomb field of *all* electrons (including the one under consideration; i.e., the one in the orbital u_{κ}) can be written as

$$U_D(\boldsymbol{\rho}_1) = \sum_{\nu} \langle u_{\nu} | \frac{1}{\rho_{12}} | u_{\nu} \rangle = \int \frac{1}{\rho_{12}} n(\boldsymbol{\rho}_2) d\boldsymbol{\rho}_2. \tag{10.32}$$

Clearly, by summing over all orbitals we overestimate the Coulomb repulsion because we include the repulsion of the probe electron in the state $|u_{\kappa}\rangle$ with its own mean field. This is called the *self energy* contribution to $U_D(\boldsymbol{\rho}_1)$ and is of course nonphysical.

Next we show that the mentioned overestimate is exactly compensated by the exchange terms. For this purpose we start from the orthonormality of the electronic orbitals, $\int u_{\nu}^*(\mathbf{r}) u_{\kappa}(\mathbf{r}) d\mathbf{r} = \delta_{\nu,\kappa}$. Summing over *all* occupied orbitals (including the one under consideration) we find exactly unity,

$$\sum_{\nu} \int u_{\nu}^*(\mathbf{r}) u_{\kappa}(\mathbf{r}) d\mathbf{r} = 1. \tag{10.33}$$

This is not surprising because all orbitals with $\nu \neq \kappa$ are orthogonal. The expression (10.33) suggest to switch summation and integration and to introduce a quantity which is called the *electron exchange density* at position $\mathbf{r}_2$ for electrons in the spinorbital α_{κ} and at position $\mathbf{r}_1$,

$$n_{ex}(\mathbf{r}_1, \mathbf{r}_2) = \sum_{\nu} \frac{u_{\nu}^*(\mathbf{r}_2) u_{\kappa}^*(\mathbf{r}_1) u_{\kappa}(\mathbf{r}_2) u_{\nu}(\mathbf{r}_1)}{|u_{\kappa}(\mathbf{r}_1)|^2} \delta_{m_s^{\kappa}, m_s^{\nu}}. \tag{10.34}$$

For electrons in different spin states $(m_s^{\kappa} \neq m_s^{\nu})$ the exchange density vanishes, $n_{ex}(\mathbf{r}_1, \mathbf{r}_2) \equiv 0$. For electrons in the same spin state $(m_s^{\kappa} = m_s^{\nu})$ the exchange density is

$$n_{ex}(\mathbf{r}, \mathbf{r}) = \sum_{\nu} u_{\nu}^*(\mathbf{r}) u_{\nu}(\mathbf{r}) \delta_{m_s^{\kappa}, m_s^{\nu}} = n_{\uparrow\uparrow}(\mathbf{r}). \tag{10.35}$$

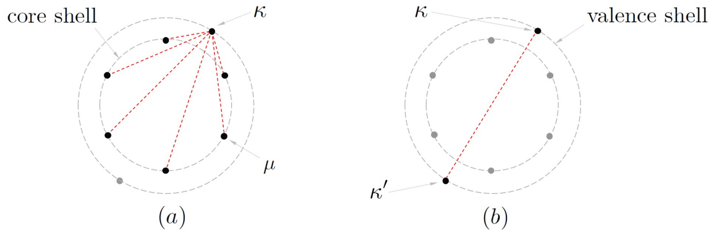

Figure 10.1: Schematic diagram of the separation into core and valence electrons: (a) *inter-shell* interaction between the valence orbital $|\kappa\rangle$ and the core orbitals $\{\mu\}$; (b) *intra-shell* interaction between the valence orbitals $|\kappa\rangle$ and $|\kappa'\rangle$ in a partially filled shell.

Note that $n_{\uparrow\uparrow}(\mathbf{r})/n(\mathbf{r})$ is the fraction of the electron density with the same spin and at the same position $\mathbf{r}$ as a probe electron in the spinorbital under consideration, $\alpha_\kappa(\mathbf{r})$. In view of Eq. (10.33) the exchange density satisfies the property

$$\int n_{ex}(\mathbf{r}_1,\mathbf{r}_2)d\mathbf{r}_2 = \delta_{m_s^\kappa,m_s^\nu}\frac{u_\kappa^*(\mathbf{r}_1)u_\nu(\mathbf{r}_1)}{|u_\kappa(\mathbf{r}_1)|^2}\sum_\nu\int u_\nu^*(\mathbf{r}_2)u_\kappa(\mathbf{r}_2)d\mathbf{r}_2 = \delta_{m_s^\kappa,m_s^\nu}. \tag{10.36}$$

For $\nu \neq \kappa$ the integral over $\mathbf{r}_2$ yields zero; for $\nu = \kappa$ the integral yields unity and the prefactor equals 1 provided the two electrons are in the same spin state. In other words, with this integral over the position of the second electron (which can be in *any* of the occupied states - including the one under consideration) we extract in total exactly one electron with spin parallel to that of the spinorbital under consideration). This is as it should be because two electrons in the same spin state cannot be found at the same position. Thus, in Slater's picture each electron of the atom is surrounded by an *exchange hole* (also called *Fermi hole*) in which electrons in the same spin state are excluded. The exchange contribution to the potential energy of an electronic charge at position $\mathbf{r}_1$ in the Coulomb field of *all* electrons can be written as

$$U_X(\boldsymbol{\rho}_1) = \sum_\nu\langle u_\nu|\frac{1}{\rho_{12}}|u_\kappa\rangle\frac{u_\kappa^*(\boldsymbol{\rho}_1)u_\nu(\boldsymbol{\rho}_1)}{|u_\kappa(\boldsymbol{\rho}_1)|^2}\delta_{m_s^\kappa,m_s^\nu} = \int\frac{1}{\rho_{12}}n_{ex}(\boldsymbol{\rho}_1,\boldsymbol{\rho}_2)d\boldsymbol{\rho}_2. \tag{10.37}$$

10.2.6 Energy functionals for valence electrons

In this section we have a special look at the valence electrons; i.e., the electrons in one or more *partially filled* shells $\{\alpha_\kappa\}$. Let α_κ be the spinorbital of one of these valence electrons. This electron will interact with the other valence electrons $\alpha_{\kappa'}$ as well as with the core electrons $\{\alpha_\mu\}$; i.e., the energy functional (10.8) can be written in the form (see Fig. 10.1)

$$H_\kappa(u_1,\cdots u_N) \equiv \langle u_\kappa|h_0|u_\kappa\rangle + \sum_\mu^{\text{core}}E(\alpha_\kappa,\alpha_\mu) + \sum_{\kappa'}^{\text{valence}}{}'E(\alpha_\kappa,\alpha_{\kappa'}). \tag{10.38}$$

Here $E(\alpha_\kappa,\alpha_\mu)$ is the Coulomb repulsion energy between the spinorbitals α_κ and α_μ. In terms of the direct and exchange integrals (7.46) this energy becomes

$$E(\alpha_\kappa,\alpha_\mu) = \left[\mathcal{J}(u_\kappa,u_\mu) - \mathcal{K}(u_\kappa,u_\mu)\delta_{m_s^\kappa,m_s^\mu}\right]. \tag{10.39}$$

Let us calculate the contribution to the core summation of *a single* closed shell, the shell nl (see Fig. 10.1a),

$$E_{nl^{2(2l+1)}}(\alpha_\kappa) \equiv \sum_\mu^{nl\,\text{shell}}E(\alpha_\kappa,\alpha_\mu). \tag{10.40}$$

The spinorbitals of this shell are $|\alpha_\mu\rangle = |nlm_l sm_s\rangle$, with $-l \leq m_l \leq l$ and $m_s = \pm\frac{1}{2}$, so the summation can be written as

$$E_{nl^{2(2l+1)}}(\alpha_\kappa) = \sum_{m_s=-1/2}^{1/2} \sum_{m_l=-l}^{l} [\mathcal{J}(nlm_l, n^\kappa l^\kappa m_{l^\kappa}) - \mathcal{K}(nlm_l, n^\kappa l^\kappa m_{l^\kappa})\delta_{m_s m_s^\kappa}] \tag{10.41}$$

$$= \sum_{m_l=-l}^{l} [2\mathcal{J}(nlm_l, n^\kappa l^\kappa m_{l^\kappa}) - \mathcal{K}(nlm_l, n^\kappa l^\kappa m_{l^\kappa})]. \tag{10.42}$$

With the aid of Eqs. (7.59) the Coulomb integrals $\mathcal{J}$ and $\mathcal{K}$ can be expressed in terms of the angular integrals a^k and b^k and the radial integrals F^k and G^k. Using the properties of a^k and b^k (see Problems 7.4, 7.5 and 7.6) the summation over m_l can be evaluated and turns out to be *independent* of m_l and m_s,

$$E_{nl^{2(2l+1)}}(\alpha_\kappa) = \sum_k \sum_{m_l=-l}^{l} [2a^k(lm_l, l^\kappa m_{l^\kappa})F^k(nl, n^\kappa l^\kappa) - b^k(m_l, m_{l^\kappa})G^k(nl, n^\kappa l^\kappa)]$$

$$= \sum_k \left[2(2l+1)F^k(nl, n^\kappa l^\kappa) - (2l+1) \begin{pmatrix} l & k & l^\kappa \\ 0 & 0 & 0 \end{pmatrix}^2 G^k(nl, n^\kappa l^\kappa) \right]. \tag{10.43}$$

This expression can be written in the form of a potential energy integral using Eqs. (7.63a),

$$E_{nl^{2(2l+1)}}(\alpha_\kappa) = \int_0^\infty U_{nl}^{(\kappa)}(\rho) \left[\tilde{R}_{n^\kappa l^\kappa}(\rho)\right]^2 \rho^2 d\rho, \tag{10.44}$$

where

$$U_{nl}^{(\kappa)}(\rho) \equiv \sum_k \left[2(2l+1)U_F^k(\rho) - (2l+1) \begin{pmatrix} l & k & l^\kappa \\ 0 & 0 & 0 \end{pmatrix}^2 \frac{\tilde{R}_{nl}(\rho)U_G^k(\rho)\tilde{R}_{n^\kappa l^\kappa}(\rho)}{\tilde{R}_{nl}(\rho)\tilde{R}_{nl}(\rho)} \right] \tag{10.45}$$

is the screening potential of the shell nl for valence electrons in the shell $n^\kappa l^\kappa$.

Repeating the above procedure for all shells of the core we write the energy functional

$$H_\kappa(u_1, \cdots u_N) \equiv \sum_{nl} \langle u_\kappa | h_0 + U_{nl}^{(\kappa)}(\rho) | u_\kappa \rangle + \sum_{\kappa'}^{\text{valence}}{}' E(\alpha_\kappa, \alpha_{\kappa'}), \tag{10.46}$$

where the sum runs over all closed shells of the atom. This is an important result. Although two equivalent valence electrons of nonzero angular momentum can have different charge distributions, as expressed by $|Y_l^m(\theta,\phi)|^2$, the screening by the electronic core is the same; i.e., independent of the magnetic quantum number m_{l^κ}. In Problem 10.1 this is explicitly verified for the electrostatic interaction of p valence electrons with a closed d shell. This result becomes intuitively clear if we realize (cf. Section 10.3) that the electronic core has a spherical charge distribution and all spherical harmonics have the same normalization.

An important consequence of the screening by the core being independent of the magnetic quantum numbers m_{l^κ} and m_{s^κ} of the valence electrons is that only the interactions *within* a valence shell determine which valence state has the lowest energy. The core electrons affect the binding of the valence electrons through screening of the nuclear charge and this can favor one valence shell over another but among equivalent electrons the core has no influence on the actual valence state with the lowest energy. The latter (i.e., the ground state) is determined by the Coulomb repulsion

Table 10.1: Coulomb repulsion energies of closed shells and of closed shells with a single valence electron.

E_{ns^2}	$= F_0(ns^2)$		
E_{np^6}	$= 15F_0(np^2) - 30F_2(np^2)$	$F_2 = F^2/25$	
$E_{nd^{10}}$	$= 45F_0(nd^2) - 70F_2(nd^2) - 630F_4(nd^2)$	$F_2 = F^2/49$	$F_4 = F^4/441$
$E_{ns^2}(n's)$	$= 2F_0(ns, n's) - G_0(ns, n's)$		
$E_{ns^2}(n'p)$	$= 2F_0(ns, n'p) - G_1(ns, n'p)$	$G_1 = G^1/3$	
$E_{ns^2}(n'd)$	$= 2F_0(ns, n'd) - G_2(ns, n'd)$	$G_2 = G^2/5$	
$E_{nd^{10}}(n'p)$	$= 10F_0(nd, n'p) - 10\,G_1(nd, n'p) - 105\,G_3(nd, n'p)$	$G_1 = G^1/15$	$G_3 = G^3/245$

between the valence electrons (see Fig. 10.1*b*). The contribution of the valence electrons to the binding energy of the atom can be written in the form

$$\varepsilon_{val} = \sum_{\kappa} I(\alpha_\kappa) + \sum_{\kappa,\mu} E(\alpha_\kappa, \alpha_\mu) + \tfrac{1}{2} \sum_{\kappa,\kappa'}{}' E(\alpha_\kappa, \alpha_{\kappa'}), \tag{10.47}$$

where $I(\alpha_\kappa) = \langle u_\kappa | h_0 | u_\kappa \rangle$ is the hydrogenic energy of the valence electron in spinorbital α_μ and the summations represent the sum over all valence (κ) and core (μ) electrons. The core contribution to the binding energy is

$$\varepsilon_{core} = \sum_{\mu} I(\alpha_\mu) + \tfrac{1}{2} \sum_{\mu,\mu'}{}' E(\alpha_\mu, \alpha_{\mu'}). \tag{10.48}$$

By summing over the angular integrals the Coulomb repulsion energy on entire configurations can be expressed in terms of a small set of Coulomb integrals, which can be evaluated numerically starting from the Hartree-Fock solutions. Some of these compact expressions are presented in Table 10.1. Once the Coulomb integrals are known it is straightforward to calculate the binding energy of the elements. For a one-electron atom (*boron*) this is demonstrated in Problem 10.2.

Problem 10.1. Show by explicit calculation that the electrostatic interaction of one p valence electron with a closed d shell is independent of the magnetic quantum numbers m_l and m_s of the p electron and given by

$$E_{nd^{10}}(n'p) = 10F_0(nd, n'p) - 10\,G_1(nd, n'p) - 105\,G_3(nd, n'p).$$

Solution. Since the d shell is closed we have $E_{nd^{10}}(p_u) = E_{nd^{10}}(\dot{p}_u) = E_{nd^{10}}(\overline{p}_u)$, with $u \in \{1, 0, -1\}$. Let us first calculate the electrostatic repulsion energy for a $\dot{p}_1$ electron:

$$\begin{aligned} E_{nd^{10}}(\dot{p}_1) = E(\dot{p}_1, \dot{d}_2) + E(\dot{p}_1, \dot{d}_1) + E(\dot{p}_1, \dot{d}_0) + E(\dot{p}_1, \dot{d}_{-1}) + E(\dot{p}_1, \dot{d}_{-2}) \\ + E(\dot{p}_1, \bar{d}_2) + E(\dot{p}_1, \bar{d}_1) + E(\dot{p}_1, \bar{d}_0) + E(\dot{p}_1, \bar{d}_{-1}) + E(\dot{p}_1, \bar{d}_{-2}). \end{aligned}$$

Using Table 7.1 we have

$$\begin{aligned} E(\dot{p}_1, \dot{d}_2) + E(\dot{p}_1, \bar{d}_2) &= 2\mathcal{J}(p_1, d_2) - \mathcal{K}(p_1, d_2) = 2F_0 + 4F_2 - 6G_1 - 3G_3 \\ E(\dot{p}_1, \dot{d}_1) + E(\dot{p}_1, \bar{d}_1) &= 2\mathcal{J}(p_1, d_1) - \mathcal{K}(p_1, d_1) = 2F_0 - 2F_2 - 3G_1 - 9G_3 \\ E(\dot{p}_1, \dot{d}_0) + E(\dot{p}_1, \bar{d}_0) &= 2\mathcal{J}(p_1, d_0) - \mathcal{K}(p_1, d_0) = 2F_0 - 4F_2 - G_1 - 18G_3 \\ E(\dot{p}_1, \dot{d}_{-1}) + E(\dot{p}_1, \bar{d}_{-1}) &= 2\mathcal{J}(p_1, d_{-1}) - \mathcal{K}(p_1, d_{-1}) = 2F_0 - 2F_2 - 30G_3 \\ E(\dot{p}_1, \dot{d}_{-2}) + E(\dot{p}_1, \bar{d}_{-2}) &= 2\mathcal{J}(p_1, d_{-2}) - \mathcal{K}(p_1, d_{-2}) = 2F_0 + 4F_2 - 45G_3. \end{aligned}$$

Adding up these contribution we find $E_{nd^{10}}(\dot{p}_1) = 10F_0 - 10G_1 - 105G_3$, where $F_0 = F^0$, $F_2 = F^2/35$, $G_1 = G^1/15$ and $G_3 = G^3/245$. The same result is obtained for $E_{nd^{10}}(\dot{p}_{-1})$. What remains to be shown is that this result is also obtained for $E_{nd^{10}}(p_0)$. For this purpose we calculate

$$\begin{aligned} E(\dot{p}_0, \dot{d}_{-2}) + E(\dot{p}_0, \bar{d}_{-2}) + E(\dot{p}_0, \dot{d}_2) + E(\dot{p}_0, \bar{d}_2) &= 4F_0 - 16F_2 - 30G_3 \\ E(\dot{p}_0, \dot{d}_{-1}) + E(\dot{p}_0, \bar{d}_{-1}) + E(\dot{p}_0, \dot{d}_1) + E(\dot{p}_0, \bar{d}_1) &= 4F_0 + 8F_2 - 6G_1 - 48G_3 \\ E(\dot{p}_0, d_0) + E(\dot{p}_0, \bar{d}_0) &= 2F_0 + 8F_2 - 4G_1 - 27G_3. \end{aligned}$$

Adding up these contribution we indeed find again $E_{nd^{10}}(p_0) = 10F_0 - 10G_1 - 105G_3$. □

Problem 10.2. Derive an expression for the ground state energy of boron (B).

Solution. Boron is a group III atom with electron configuration $1s^22s^22p$; i.e., with the $2p$ electron as the only valence electron. The Coulomb energy of the ground state can be written as

$$\varepsilon(1s^2,2s^2,2p) = 2I(1s) + 2I(2s) + I(2p) + E_{1s^2} + E_{2s^2} + E_{1s^2}(2s^2) + E_{1s^2}(2p) + E_{2s^2}(2p),$$

where $I(nl) = \langle nl|h_0|nl\rangle$ is the hydrogenic energy of a single electron. The Coulomb repulsion energies are found with Table 7.1: $E_{1s^2} = E(1\dot{s},1\bar{s}) = F_0(1s^2)$, $E_{2s^2} = F_0(2s^2)$, $E_{1s^2}(2s^2) = E_{1s^2}(2\dot{s}) + E_{1s^2}(2\bar{s}) = 4F_0(2s,1s) - 2G_0(2s,1s)$, $E_{1s^2}(2p) = 2F_0(2p,1s) - G_1(2p,1s)$ and $E_{2s^2}(2p) = 2F_0(2p,2s) - G_1(2p,2s)$, with $F_0 = F^0$, $G_0 = G^0$ and $G_1 = G^1/3$. Adding the various terms the Coulomb energy becomes

$$\begin{aligned}\varepsilon(1s^22s^22p) = {} & 2I(1s) + 2I(2s) + I(2p) + F_0(1s^2) + F_0(2s^2)\\ & + 4F_0(2s,1s) - 2G_0(2s,1s) + 2F_0(2p,1s) - G_1(2p,1s) + 2F_0(2p,2s) - G_1(2p,2s). \quad \square\end{aligned}$$

10.3 Atoms with zero orbital angular momentum

At this point we can start the search for the physics underlying the Hund rules. It will be our goal to predict the angular momentum of the ground state of an arbitrary element of the periodic system. The period and group of the element provides an Ansatz for the atomic ground state configuration, adequate in most cases but with some interesting exceptions. To determine the state of angular momentum of the ground states we proceed in steps. First we consider atoms with a ground-state configuration of only closed shells. Then we look at half-filled shells. In subsequent sections we add new aspects to the analysis until we can handle the most general case. The Hund rules turn out not to be of general validity but nevertheless provide valuable guidance to sharpen our understanding of the physics that determines the ground states of atomic systems.

10.3.1 Closed shell atoms - ${}^1S_0$

We start with atoms composed of only closed (sub)shells. For closed shells of given values of n and l, only *a single* nonzero Slater determinant can represent the angular momentum state of the atom,

$$|\dot{l},\bar{l},\cdots,\dot{0},\bar{0},\cdots,-\dot{l},-\bar{l}\rangle_{nl^{2(2l+1)}}. \tag{10.49}$$

Moreover, the magnetic quantum numbers of the spinorbitals add up to zero,

$$M_L = 2\sum_{m_l} m_l = 0 \quad \text{and} \quad M_S = 0. \tag{10.50}$$

Hence, the angular momentum Hilbert space is one-dimensional, which means that the total orbital and the total spin angular momentum have to be zero ($L = 0$, $S = 0$); i.e., closed-shell atoms are characterized by a ${}^1S_0$ term. The charge distribution is *spherical* as can be made explicit with the aid of the addition theorem (L.56) for the case $\hat{\mathbf{r}} = \hat{\mathbf{r}}'$,

$$2\sum_{m=-l}^{l} |Y_l^m(\hat{\mathbf{r}})|^2 = 2\frac{(2l+1)}{4\pi}. \tag{10.51}$$

This is known as *Unsöld's theorem* [115].

There are several types of neutral atoms with only closed shells. Best known are of course the inert gases (group VIII) *helium* (He), *neon* (Ne), *argon* (Ar), *krypton* (Kr), *xenon* (Xe) and *radon* (Rn). Secondly, the *two-electron atoms*. These include the alkaline-earth elements (group II) *beryllium* (Be), *magnesium* (Mg), *calcium* (Ca), *strontium* (Sr), *barium* (Ba) and *radium* (Ra). Further, the transition elements *zinc* (Zn), *cadmium* (Cd) and *mercury* (Hg) (group 12) and the

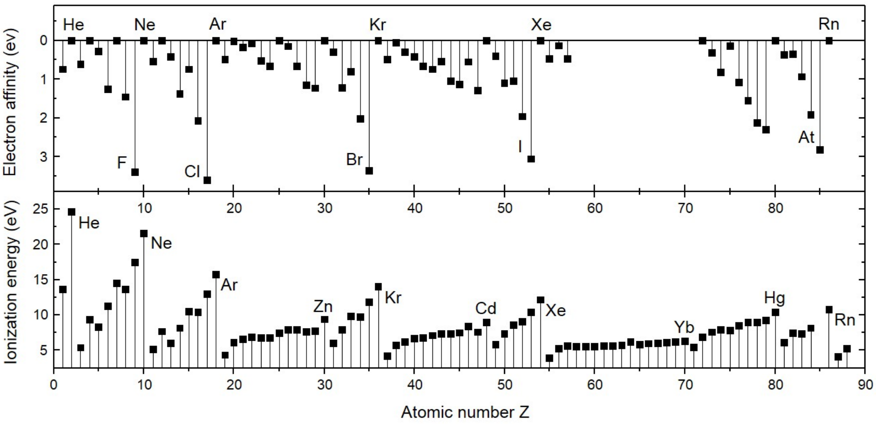

Figure 10.2: Ionization energies and electron affinities of the elements.

rare-earth elements *ytterbium* (Yb) and *nobelium* (No). In all these cases the *electron affinity* (i.e., the ionization energy of the negative ion with the strongest binding energy) is either zero or small as is shown in the upper panel of Fig. 10.2 (cf. Appendix C). The difference is in the *ionization energies*, which are largest for the inert gases as can be seen in the lower panel of Fig. 10.2. This difference arises from the difference in occupation of the shells. For the alkaline-earth elements only two electrons in ns shells share the Coulomb attraction of the nucleus, whereas the filled $2p$ shell (Ne) contains 6 electrons, the filled $3d$ shell (Zn) 10, *etc.*. For a growing number of electrons in a given shell, the binding increases because for neutral atoms the nuclear charge increases with the shell occupation; hence also the ionization energy. So, it takes more energy to pull an electron from a shell of 6 than from a shell of 2 electrons. This effect is counteracted by the electrostatic repulsion of the electrons within a shell, which is large in small shells and small in large shells. As the relative increase in binding is largest for small Z, the differences in ionization energy are most pronounced in the first few rows of the periodic system.

For the inert gases Ne and Ar both the s shell and the p shell are closed; for Kr and Xe this holds for the s, p and d shells; for Rn for the s, p, d and f shells. As the screening efficiency by the core electrons increases with increasing Z the ionization energy of the inert gases decreases accordingly; i.e., Rn is much less *inert* than He.

10.3.2 Atoms with half-filled shells - ${}^{2J+1}S_J$

Let us next turn to atoms with a ground-state configuration of closed shells plus one *half-filled* shell of given values of n and l. In this case again only *a single* nonzero Slater determinant can represent the angular momentum state of the atom. This is the fully symmetric spin state, which can only be combined with an antisymmetric orbital state for the Pauli principle to be satisfied,

$$|\dot{l}, \cdots, \dot{0}, \cdots, -\dot{l}\rangle_{nl^{(2l+1)}}. \tag{10.52}$$

As discussed for the helium atom, antisymmetric orbital states minimize the Coulomb repulsion between the electrons, exactly as we require for atomic ground states. In other words, the total spin is maximized by quantum correlations since alignment of the spins minimizes the Coulomb repulsion within the shell. The magnetic quantum numbers of the state (10.52) add up to

$$M_L = \sum_{m_l} m_l = 0 \quad \text{and} \quad M_S = \tfrac{1}{2}(2l+1) = S. \tag{10.53}$$

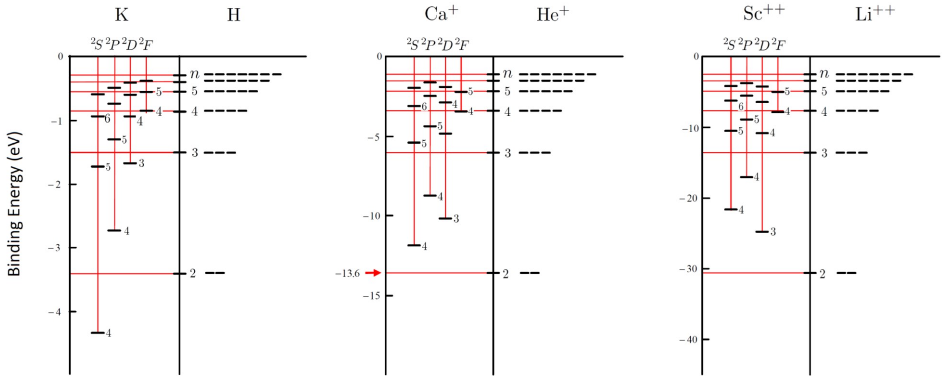

Figure 10.3: Example of three isoelectronic systems (K , Ca$^+$ and Sc^{++}) with one valence electron outside the core configuration of argon. With increasing nuclear charge the screening of the 4s electron by the 3d electron becomes more effective up to the point that the 3d electron is energetically favored; i.e., the ground state is no longer alkali like.

Hence, also in the case of half-filled shells the orbital angular momentum subspace is one-dimensional and the total orbital angular momentum has to be zero ($L = 0$). As a consequence also the charge distribution is spherical. The ground-state terms are of the type $^{2J+1}S_J$, with $J = S = l + \frac{1}{2}$.

Let us look at a few examples: all ground states with three equivalent p electrons are of the type $^4S_{3/2}$. This holds for *nitrogen* (N), *phosphorus* (P), *arsenic* (As), *antimony* (Sb) and *bismuth* (Bi). Likewise, we have for five equivalent d electrons $^6S_{5/2}$. This holds for *manganese* (Mn), *technetium* (Tc) and *rhenium* (Re). For the seven equivalent f electrons of *europium* (Eu) we have $^8S_{7/2}$ (cf. Appendix C). *Chromium* (Cr) and *molybdenum* (Mo) are special because in these cases both an s shell and a d shell are half filled.

10.4 Atoms with one valence electron

10.4.1 Competition between electron configurations

We found that in closed shells both L and S are zero. This immediately implies that for all one-electron atoms the total angular momentum is equal to the angular momentum of the valence electron. Interestingly, in *potassium* (K) the 4s shell starts to be populated rather than the 3d shell. The same preference holds for the 5s shell over the both the 4d and 4f shells. This is the case of *rubidium* (Rb). In *indium* (In) the occupation of the 5p shell is preferred over the 4f shell. These preferences originate in differences of penetration of the various nl orbitals of the valences electrons into the closed shells of *core electrons*. The $R_{ns}(\rho)$ wavefunctions penetrate all the way to the nucleus. Therefore, the electron core is less effective in screening the nucleus for s electrons than for p, d, f electrons.

Anomalies occur in the periodic table when two configurations have approximately the same energy. This holds for instance for the [Ar]$3d^54s^1$ and [Ar]$3d^44s^2$ configurations of *chromium* (Cr) and for the [Ar]$3d^{10}4s^1$ and [Ar]$3d^94s^2$ configurations of *copper* (Cu). In both cases the occupation of the 3d shell is marginally favored over that of the 4s shell (cf. Appendix C). Other examples are the [Kr]$4p^64d^45s$ and [Kr]$4p^64d^35s^2$ configurations of *niobium* (Nb) and the [Xe]$4f^{14}5d^96s$ and [Xe]$4f^{14}5d^86s^2$ configurations of *platinum* (Pt). In such cases it is more difficult to estimate the ground state energy because the electronic wavefunction cannot be properly approximated by a single configuration. This phenomenon is referred to as *configuration interaction*. In theories it is accounted for by using a linear combination of configurations for the electronic state (cf. Section 10.2.2).

As an example of the arguments that come into play when discussing configuration interaction we compare the configuration of *potassium* (K) with that of *copper* (Cu). Starting from the closed shell configuration [Ar] we note that the $4s$ *electron* is favored over the $3d$ *electron.* However, starting from the closed shell configuration [Zn], we note that the $4s$ *hole* is favored over the $3d$ *hole.* How can this be if the $4s$ electron state is preferentially bound? This paradox shows that, apparently, the preferred binding of the $4s$ electron observed in K is lost in the case of Cu. This can be understood by considering the strong increase in nuclear charge along the 4^{th} period, from $Z_{\mathrm{K}} = 19$ to $Z_{\mathrm{Cu}} = 29$.

As screening is always incomplete, the increase in Z tends to increase the binding of *all* electrons but the actual increase depends on screening details of the individual orbitals:

- *Screening by the core:* As the core electrons of *potassium* $(1s, 2s, 2p, 3s)$ are least screened, the increase in binding energy with increasing Z is strongest for these electrons. This results in core contraction. The contraction of the $3d$ orbital (and to a lesser extent the $4p$ orbital) is more pronounced than that of the $4s$ orbital (because the $4s$ electron always probes the nucleus). This phenomenon is sometimes referred to as the collapse of the $3d$ shell. We can convince ourselves about this effect by comparing the energy levels of *potassium* (K), singly ionized *calcium* (Ca^+) and doubly ionized *scandium* (Sc^{2+}), which are *isoelectronic* (i.e., have the same number of electrons) but differ in the nuclear charge - see Fig. 10.3. Actually, the electronic ground state configurations of the transition-metal ions Sc^{2+}, Ti^{3+}, V^{4+}, *etc.*, are all $[\mathrm{Ar}]3d^1$. This shows that even a modest increase in nuclear charge from $Z_{\mathrm{K}} = 19$ to $Z_{\mathrm{Sc}} = 21$ is sufficient to remove the penetration advantage of the $4s$ electron and favor the $3d$ electron.

- *Screening by the valence electrons:* The collapsed $3d$ shell acts as an additional screening layer for the $4s$ electrons. Therefore, with growing $3d$ occupation (along the 4^{th} period) the binding of the $4s$ electron erodes by $3d$ screening up to the point that a $3d$ electron is favored. This first happens for *chromium* (Cr) and later in the period for *copper* (Cu). Beyond Cr the $4s$ electron is again favored because all $3d$ orbitals are already occupied once and screening of an additional $3d$ electron by the others is more effective at double occupation (not reduced by quantum correlations). Yet, as the increase in Z continues along the 4^{th} period the story repeats itself: with the $4s$ shell closed the $3d$ occupation resumes and the $4s$ binding erodes until the $3d$ electron is again favored at $Z = 29$. This manifests itself as the $4s$ hole in the configuration of Cu.

10.4.2 Core polarization - unrestricted Hartree-Fock method

Thus far in calculating Coulomb repulsion we presumed that all electrons of a closed shell have the same radial wavefunction. In Section 7.1.3 we briefly abandoned this restriction and found that to achieve binding of H^- the two electrons of the $1s$ shell should have different Bohr radii; i.e., half of the shell is compressed and the other half is inflated. In the case of H^- this arises from the correlation in the electron motion, which tends to keep the inter-electronic separation as large as possible. We now consider a similar phenomenon but with quantum correlations at its origin. The principle is illustrated in Fig. 10.4 where we show a schematic diagram in which the $3s$ electron of *sodium* (Na) interacts with the $2p^6$ core shell. The Coulomb repulsion energy between the valence electron and the $2p^6$ shell is given by a part which includes exchange

$$E(3\dot{s}, 2\dot{p}_1) + E(3\dot{s}, 2\dot{p}_0) + E(3\dot{s}, 2\dot{p}_{-1}) = 3F_0 - 3G_1, \tag{10.54}$$

where $G_1 = G^1/3$ and a part which does *not* include exchange (see Problem 9.5)

$$E(3\dot{s}, 2\bar{p}_1) + E(3\dot{s}, 2\bar{p}_0) + E(3\dot{s}, 2\bar{p}_{-1}) = 3F_0. \tag{10.55}$$

As the Coulomb repulsion is less in the former case, the up-spin part of the core will be less compressed by the valence electron than the down-spin part. To allow for this effect one has to use different orbitals for spin-up and spin-down in the Hartree-Fock optimization. This is known as the

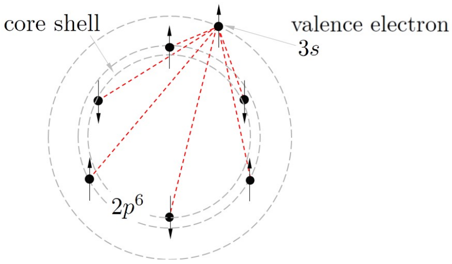

Figure 10.4: Principle of core polarization by a spin-up valence electron. The Coulomb repulsion by the core shell differs for spin-up and spin-down core electrons due to the presence (spin-up) or absence (spin-down) of the exchange contribution. In the diagram this is illustrated by splitting the $2p^6$ core shell into two shells of slightly different diameter.

unrestricted Hartree-Fock method. This approach requires the use of twice as many core orbitals as in the ordinary Hartree-Fock method introduced in Section 10.2.3. The latter is called the *restricted* Hartree-Fock method because all electrons within a closed shell are forced to have the same radial wavefunction, irrespective of the spin state. An important consequence of the separation of the core shells in a spin-up and a spin-down part is the appearance of a spin density which is *globally balanced* but *locally not*. This is called local polarization of the electron core. Of particular importance is core polarization of s shells as this gives rise to a nonzero electron spin density at the nucleus, which is rigorously absent in the restricted Hartree-Fock picture. This gives rise to an *induced* Fermi contact interaction. This contact interaction can also be induced by valence electrons with $l \neq 0$. As the induced spin at the nucleus is opposite to the spin of the polarizing valence electron it tends to suppress the hyperfine splitting for parallel coupling ($j = l + s$) and to enhance the splitting for antiparallel coupling ($j = l - s$). This can give rise to a level inversion of the hyperfine levels as is illustrated for the $2\,^2P_{1/2}$ and $2\,^2P_{3/2}$ fine-structure doublet of ^{7}Li in Fig. 5.3.

10.5 Atoms with more than one valence electron - Hund's Rule 1 & 2

10.5.1 Introduction

Thus far we have been dealing with an unambiguous angular momentum state of the atom. Once we have more than one valence electron in a partially filled shell (but not half filled) matters complicate considerably because by coupling of angular momenta more than one angular momentum state can be associated with a given electron configuration. So, it takes an additional effort to determine which angular momentum state (LS term) corresponds to the electronic ground state of a given electron configuration. The first two Hund rules provide us with a rapid assessment of the LS term corresponding to the electronic ground state.

In the present section we determine for a given electron configuration which LS terms are consistent with Fermi-Dirac statistics; i.e., can be expressed as a linear combination of (nonzero) Slater determinants. Once we know the relevant LS terms we calculate their electrostatic energies and demonstrate that the first two Hund rules correctly predict (in practically all cases) the LS term of lowest electrostatic repulsion between the valence electrons, which corresponds to the electronic ground state of a given electron configuration.

10.5.2 Partially filled shells with np^2 configuration

As the first case of a partially filled shell with two electrons we consider the np^2 configuration. This is the case of the group IV atoms C, Si, Ge, Sn and Pb. In the absence of the Pauli principle the electronic pair state $|\psi_{12}\rangle$ can be expressed as a linear combination of the $(2l+1)^2(2s+1)^2 = 36$

Table 10.2: Example np^2 configuration: (top) uncoupled representation - the 15 linearly independent pair states consistent with the Pauli principle; (bottom) coupled representation - all LS terms (including degeneracy these yield 36 linearly independent states).

np^2		M_S			deg.
uncoupled		1	0	-1	15
M_L	2		$\lvert\dot{1},\bar{1}\rangle$		1
	1	$\lvert\dot{1},\dot{0}\rangle$	$\lvert\dot{1},\bar{0}\rangle\lvert\bar{1},\dot{0}\rangle$	$\lvert\bar{1},\bar{0}\rangle$	4
	0	$\lvert\dot{1},-\dot{1}\rangle$	$\lvert\dot{1},-\bar{1}\rangle\lvert\dot{0},\bar{0}\rangle\lvert\bar{1},-\dot{1}\rangle$	$\lvert\bar{1},-\bar{1}\rangle$	5
	-1	$\lvert\dot{0},-\dot{1}\rangle$	$\lvert\dot{0},-\bar{1}\rangle\lvert\bar{0},-\dot{1}\rangle$	$\lvert\bar{0},-\bar{1}\rangle$	4
	-2		$\lvert-\dot{1},-\bar{1}\rangle$		1

np^2		L			deg.
coupled		0	1	2	36

	1	${}^3S_1$	${}^3P_2, {}^3P_1, {}^3P_0$	${}^3D_3, {}^3D_2, {}^3D_1$	27

basis states of the *uncoupled* representation $\{|nlm_{l_1}sm_{s_1}\rangle \otimes |nlm_{l_2}sm_{s_2}\rangle\}$ with $l = 1$ and $s = \frac{1}{2}$. Using a basis transformation this basis can be reexpressed into a basis of

$$\binom{6}{2} = 15 \tag{10.56}$$

fully antisymmetric and 21 partly or fully symmetric *linearly independent* states. For equivalent electrons the 21 partly or fully symmetric basis states have to be excluded on the basis of the Pauli principle. The leaves a 15-dimensional Hilbert space consistent with the Pauli principle. The 15 *linearly independent* antisymmetric states are readily identified in the Slater determinant notation. In Table 10.2 they are grouped by the values of $M_L = m_{l_1} + m_{l_2}$ and $M_S = m_{s_1} + m_{s_2}$.

Further insight into the role of the Pauli principle for partially filled shells is obtained by analyzing the np^2 configuration in the *coupled representation* of the total orbital angular momentum $\mathbf{L} = \boldsymbol{l}_1 + \boldsymbol{l}_2$ coupled with the total spin $\mathbf{S} = \boldsymbol{s}_1 + \boldsymbol{s}_2$ into the total angular momentum $\mathbf{J} = \mathbf{L} + \mathbf{S}$. In a potential field of central symmetry J is a good quantum number. For the np^2 configuration the total orbital angular quantum number can take the values $L = 0, 1, 2$ with possible total spin $S = 0, 1$. In the coupled representation $\{|JM_J\rangle\}$ we have 9 *singlet* states ($S = 0$) and 27 *triplet* states ($S = 1$); i.e., together again 36 atomic states can be identified. In the absence of spin-orbit coupling these are all degenerate. In the LS-term notation these 36 states are also given in Table 10.2. Three questions immediately arise:

1. which of these LS terms are consistent with the Pauli principle?
2. what is the relation between the LS terms and the Slater determinants?
3. which term has the lowest energy?

10.5.2.1 Determination of LS terms consistent with Pauli principle

To answer the first question we are guided by the knowledge that the dimension of the anti-symmetric subspace is independent of the choice of basis. Hence we search for 15 basis states in the coupled representation. This is done with the aid of a decision table. For the np^2 configurations this is Table 10.3.

We start with the angular momentum state of the largest multiplicity, i.e., the ${}^3D$ sector of the coupled representation. This sector is not contained in the anti-symmetric subspace because for $L = 2$ and $S = 1$ the ${}^3D$ sector must include the Slater determinant $|\dot{1},\dot{1}\rangle$, which corresponds to

Table 10.3: Decision table for np^2 configurations using the known LS-term degeneracy to determine the spin-orbit Terms consistent with the Pauli principle for two equivalent p-electrons.

[†] The sliced-arrow notation has no significance other than being compact.

$M_L = m_{l_1} + m_{l_2} = 2$ and $M_S = m_{s_1} + m_{s_2} = 1$. But this determinant violates the Pauli principle and therefore has to be excluded.

Continuing with the triplet manifolds, we turn to the ^3P sector, which is the largest of the remaining sectors. Since $L = 1$ and $S = 1$, the ^3P sector must include the Slater determinant $|\dot{1}, \dot{0}\rangle$, which corresponds to $M_L = m_{l_1} + m_{l_2} = 1$ and $M_S = m_{s_1} + m_{s_2} = 1$. Hence, we identify: $|\dot{1}, \dot{0}\rangle = |^3P; M_L = 1, M_S = 1\rangle$. In Problem 9.7 we calculated L with the algebraic method of Eq. 9.98 (which requires a larger effort than the dimensional analysis of the present section). Because the determinant $|\dot{1}, \dot{0}\rangle$ is consistent with the Pauli principle it must be within the anti-symmetric part of the Hilbert space. Actually, this must hold for the whole ^3P sector because all eigenstates of this sector can be generated from $|\dot{1}, \dot{0}\rangle$ with the shift operators $L_\pm$ and $S_\pm$ and these preserve the antisymmetric symmetry - see Eq. (9.94) and question b.). Furthermore, because the ^3P sector represents a 3×3-fold degenerate manifold, also 9 linearly independent determinants are required to represent the ^3P sector for all combinations of $M_S = 1, 0, -1$ and $M_L = 1, 0, -1$. These 9 possibilities are collected in Table 10.4 along with the basis states of the ^1D and ^1S sectors, which are also Pauli-allowed (compare with Table 10.4-top).

Next we turn to the ^3S sector, for which $L = 0$ and $S = 1$. This sector has to be excluded because there is only a single Slater determinant with $M_S = 1$ and $M_L = 0$ consistent with the Pauli principle but this one was already assigned as part of the ^3P manifold. So, we proceed with the singlet sectors. First ^1D ($L = 2; S = 0$), this 1×5-fold degenerate sector includes the Slater determinant $|\dot{1}, \bar{1}\rangle$, which is allowed by the Pauli principle. Thus the ^1D sector must be part of the subspace spanned by 5 linearly independent Slater determinants corresponding to all combinations of $M_S = 0$ and $M_L = 2, 1, 0, -1, -2$ (these 5 possibilities are collected Table 10.4).

At this point we assigned $9 + 5 = 14$ of the 15 basis states, which leaves only a single non-degenerate sector; i.e., a $^1S_0$ term (also collected in Table 10.4). The same result is also obtained by continuing the procedure of Table 10.3 until we decided on all LS terms. Note that in view of the symmetry of the table only the non-positive (or the non-negative) $M_J = M_L + M_S$ values suffice to assign all LS terms. We found that only the ^3P, ^1D and ^1S sectors are consistent with the Pauli principle. In the coupled representation this implies the terms $^3P_2$, $^3P_1$, $^3P_0$, $^1D_2$ and $^1S_0$. Including their degeneracies we recover again the $5+3+1+5+1 = 15$-dimensional subspace of antisymmetric states identified at the beginning of this section (see Table 10.5).

10.5.2.2 The LS terms decomposed as linear combinations of Slater determinants

Let us turn to the second question. At this point we have identified all LS terms of the np^2 configurations consistent with the Pauli principle. It would be nice if a unique mapping would

Table 10.4: Multiplicity analysis of the upper part of Table 10.2 to identify the 15 linearly independent LS terms of the np^2 configuration consistent with the Pauli principle. Note the 3×3 block of the ^3P sector, the 1×5 block of the ^1D sector and the 1×1 block of the ^1S sector.

$\vert^{2S+1}L; M_L, M_S\rangle$		M_S			deg.
(coupled)		1	0	-1	15
M_L	2		$\vert^1D; 2, 0\rangle$		1
	1	$\vert^3P; 1, 1\rangle$	$\vert^3P; 1, 0\rangle\vert^1D; 1, 0\rangle$	$\vert^3P; 1, -1\rangle$	4
	0	$\vert^3P; 0, 1\rangle$	$\vert^3P; 0, 0\rangle\vert^1S; 0, 0\rangle\vert^1D; 0, 0\rangle$	$\vert^3P; 0, -1\rangle$	5
	-1	$\vert^3P; -1, 1\rangle$	$\vert^3P; -1, 0\rangle\vert^1D; -1, 0\rangle$	$\vert^3P; -1, -1\rangle$	4
	-2		$\vert^1D; -2, 0\rangle$		1

exist onto the Slater determinants. Unfortunately this is generally not the case. Exceptions are the LS-term states $|LM_L, SM_S\rangle \equiv |^{2S+1}L; M_L, M_S\rangle$ for which a single LS term combines with a single determinant in Table 10.3,

$$|^3P; 1, 1\rangle = |\dot{1}, \dot{0}\rangle_{np^2} \tag{10.57}$$

$$|^1D; 2, 0\rangle = |\dot{1}, \bar{1}\rangle_{np^2}. \tag{10.58}$$

The first example corresponds to a stretched spin state ($M_S = S = 2s = 1$), the second with a stretched orbital angular momentum state ($M_L = L = 2l = 2$). Being stretched states these examples represent eigenstates of the total spin and the total angular momentum, respectively (see Problem 9.8). To find the other basis states of the ^3P sector in the Hilbert space of the np^2 configuration we compare the action of the spin lowering operator S_- in both representations,

$$S_\pm|\psi_\alpha\rangle = \begin{cases} \sqrt{S(S+1) - M_S(M_S \pm 1)}\,\hbar\,|\psi_\alpha(M_S \pm 1)\rangle \\ \sum_\kappa \sqrt{s(s+1) - m_s^\kappa(m_s^\kappa \pm 1)}\,\hbar\,|\psi_\alpha(m_s^\kappa \pm 1)\rangle. \end{cases} \tag{10.59}$$

Starting from the stretched spin state (10.57) we calculate

$$\left.\begin{aligned} S_-|^3P; 1, 1\rangle &= \sqrt{2}\,\hbar\,|^3P; 1, 0\rangle \\ S_-|\dot{1}, \dot{0}\rangle_{np^2} &= \hbar\,|\bar{1}, \dot{0}\rangle_{np^2} + \hbar\,|\dot{1}, \bar{0}\rangle_{np^2} \end{aligned}\right\} \to |^3P; 1, 0\rangle = \sqrt{\tfrac{1}{2}}\left[|\dot{1}, \bar{0}\rangle_{np^2} + |\bar{1}, \dot{0}\rangle_{np^2}\right]. \tag{10.60}$$

Although it is a bit laborious we may convince ourselves explicitly with Eqs. (9.98), (9.92), (9.110) and (9.108) that the r.h.s. of Eq. (10.60) is indeed an eigenstate of $\mathbf{L}^2, L_z, \mathbf{S}^2$ and S_z. To find the

Table 10.5: Coupled and uncoupled basis states for np^2 configurations. In both cases we can identify 15 linearly independent pair states spanning the antisymmetric subspace in which the Pauli principle is satisfied.

uncoupled					coupled						
M_L					$\vert J, M_J\rangle$

	$\vert\dot{1}, \bar{0}\rangle\vert\bar{1}, \dot{0}\rangle$	$\vert\dot{1}, -\dot{1}\rangle$			$\vert 2, 1\rangle$	$\vert 2, 1\rangle$	$\vert 1, 1\rangle$			1	
	$\vert\bar{1}, \bar{0}\rangle$	$\vert\dot{1}, -\bar{1}\rangle\vert\dot{0}, \bar{0}\rangle\vert\bar{1}, -\dot{1}\rangle$	$\vert\dot{0}, -\dot{1}\rangle$		$\vert 2, 0\rangle$	$\vert 2, 0\rangle$	$\vert 1, 0\rangle$	$\vert 0, 0\rangle$	$\vert 0, 0\rangle$	0	
		$\vert\bar{1}, -\bar{1}\rangle$	$\vert\dot{0}, -\bar{1}\rangle\vert\bar{0}, -\dot{1}\rangle$		$\vert 2, -1\rangle$	$\vert 2, -1\rangle$	$\vert 1, -1\rangle$			-1	
			$\vert\bar{0}, -\bar{1}\rangle$	$\vert -\dot{1}, -\bar{1}\rangle$	$\vert 2, -2\rangle$	$\vert 2, -2\rangle$				-2	

basis of the ^1D sector in the Hilbert space of the np^2 configuration we compare the action of the orbital lowering operator L_- on both representations

$$L_\pm|\psi_\alpha\rangle = \begin{cases} \sqrt{L(L+1)-M_L(M_L\pm 1)}\,\hbar\,|\psi_\alpha(M_L\pm 1)\rangle \\ \sum_\kappa \sqrt{l^\kappa(l^\kappa+1)-m_l^\kappa(m_l^\kappa \pm 1)}\,\hbar\,|\psi_\alpha(m_l^\kappa\pm 1)\rangle. \end{cases} \tag{10.61}$$

Starting from the stretched orbital angular momentum state (10.58) we obtain

$$\left.\begin{aligned} L_-|^1D;2,0\rangle &= 2\hbar\,|^1D;1,0\rangle \\ L_-|\dot{1},\bar{1}\rangle_{np^2} &= \sqrt{2}\,\hbar\,|\dot{0},\bar{1}\rangle_{np^2} + \sqrt{2}\,\hbar\,|\dot{1},\bar{0}\rangle_{np^2} \end{aligned}\right\} \rightarrow |^1D;1,0\rangle = \sqrt{\tfrac{1}{2}}\left[|\dot{1},\bar{0}\rangle_{np^2} - |\bar{1},\dot{0}\rangle_{np^2}\right]. \tag{10.62}$$

The minus sign appeared when the determinantal state $|\dot{0},\bar{1}\rangle_{np^2}$ was brought to standard order. Note that the states $|^3P;1,0\rangle$ and $|^1D;1,0\rangle$ are orthogonal eigenstates of $\mathbf{L}^2, L_z, \mathbf{S}^2$ and S_z, both composed of the same Slater determinants.

To express the basis state $|^1S;0,0\rangle$ of the ^1S sector in Slater determinants we have to take a different approach because this sector does not contain a stretched state. However, we can use the L_- operator to construct the states $|^3P;0,0\rangle$ and $|^1D;0,0\rangle$, which both must be orthogonal to $|^1S;0,0\rangle$. For the state $|^3P;0,0\rangle$ we find with the aid of Eqs. (10.60) and (9.94)

$$\left.\begin{aligned} L_-|^3P;1,0\rangle &= \sqrt{2}\,\hbar\,|^3P;0,0\rangle \\ L_-\sqrt{\tfrac{1}{2}}\left[|\dot{1},\bar{0}\rangle_{np^2} + |\bar{1},\dot{0}\rangle_{np^2}\right] &= \hbar\,|\dot{1},-\bar{1}\rangle_{np^2} + \hbar\,|\bar{1},-\dot{1}\rangle_{np^2} \end{aligned}\right\} \rightarrow$$

$$\rightarrow |^3P;0,0\rangle = \sqrt{\tfrac{1}{2}}\left[|\dot{1},-\bar{1}\rangle_{np^2} + |\bar{1},-\dot{1}\rangle_{np^2}\right]. \tag{10.63}$$

Analogously we find with the aid of Eq. (10.62) for the state $|^1D;0,0\rangle$

$$\left.\begin{aligned} L_-|^1D;1,0\rangle &= \sqrt{6}\,\hbar\,|^1D;0,0\rangle \\ L_-\sqrt{\tfrac{1}{2}}\left[|\dot{1},\bar{0}\rangle_{np^2} - |\bar{1},\dot{0}\rangle_{np^2}\right] &= 2\hbar\,|\dot{0},\bar{0}\rangle_{np^2} + \hbar\,|\dot{1},-\bar{1}\rangle_{np^2} - \hbar\,|\bar{1},-\dot{1}\rangle_{np^2} \end{aligned}\right\} \rightarrow$$

$$\rightarrow |^1D;0,0\rangle = \sqrt{\tfrac{1}{6}}\left[2|\dot{0},\bar{0}\rangle_{np^2} + |\dot{1},-\bar{1}\rangle_{np^2} - |\bar{1},-\dot{1}\rangle_{np^2}\right]. \tag{10.64}$$

What remains to be done is to find the coefficients that orthonormalize the linear combination $|^1S;0,0\rangle = a|\dot{0},\bar{0}\rangle_{np^2} + b|\dot{1},-\bar{1}\rangle_{np^2} + c|\bar{1},-\dot{1}\rangle_{np^2}$ with respect to both $|^3P;0,0\rangle$ and $|^1D;0,0\rangle$. To be orthogonal to $|^3P;0,0\rangle$ we require $\sqrt{1/2}\,b + \sqrt{1/2}\,c = 0 \Rightarrow b = -c$. To be also orthogonal to $|^1D;0,0\rangle$ the coefficients should satisfy the relation $\sqrt{2/3}\,a - \sqrt{1/6}\,c - \sqrt{1/6}\,c = 0 \Rightarrow a = c$. Thus, the normalized linear combination is

$$|^1S;0,0\rangle = \sqrt{\tfrac{1}{3}}\left[|\dot{0},\bar{0}\rangle_{np^2} - |\dot{1},-\bar{1}\rangle_{np^2} + |\bar{1},-\dot{1}\rangle_{np^2}\right]. \tag{10.65}$$

10.5.2.3 The first Hund rule

The remaining question concerns the energies of the LS terms. First of all we note that all the terms identified in Table 10.3 have the same energy in the screened Coulomb field of the nucleus,

$$E_c(np^2) = -2\times hcR_\infty Z_{np}^2/n^2, \tag{10.66}$$

where Z_{np} has to be determined experimentally, or theoretically by numerical integration of the radial Schrödinger equation for a p-electron ($l = 1$) in the screened Coulomb field of the nucleus. Therefore, the electrostatic repulsion between the electrons determines which LS term has the lowest energy and this repulsion is smallest for the largest average separation between the electrons. In view of Pauli exclusion of close approach of identical fermions, we may argue that the symmetric spin states (the states with the largest total spin S) are energetically most favorable (like in the helium ground state). This insight provides the physics behind the *first Hund rule*:

> The *Coulomb repulsion* between the valence electrons of an atomic ground state configuration is *minimal for the maximum (Pauli-allowed) value of the total spin*, S.

For the np^2 configuration the terms with the largest spin ($S = 1$) are the triplet terms ${}^3P_{2,1,0}$. The ground state of carbon is indeed a ${}^3P$ term: ${}^3P_0$ (cf. Appendix C). To decide among the terms ${}^3P_2$, ${}^3P_1$ and ${}^3P_0$ we need the *third Hund rule.* This rule originates in the spin-orbit interaction and will be discussed in Section 10.6.

Calculation of Term energies: Let us explicitly verify the validity of the first Hund rule by calculating the energy of the three LS terms identified above. Because in zero field the energy is independent of the magnetic quantum numbers it can be determined for any value of M_L and M_S. First we calculate the energy for the stretched states. In Hartree atomic units the electrostatic repulsion energy of the ${}^3P$ term is given by

$$E({}^3P) = \langle \dot{1}, \dot{0}| \frac{1}{\rho_{12}} |\dot{1}, \dot{0}\rangle_{np^2}. \tag{10.67}$$

This is a diagonal matrix element of a two-body operator and using Eq. (9.52) we find

$$E({}^3P) = (p_1, p_0| \frac{1}{\rho_{12}} |p_1, p_0) - (p_0, p_1| \frac{1}{\rho_{12}} |p_1, p_0) = \mathcal{J} - \mathcal{K}, \tag{10.68}$$

where $\mathcal{J} = (p_1, p_0|\rho_{12}^{-1}|p_1, p_0)$ and $\mathcal{K} = (p_0, p_1|\rho_{12}^{-1}|p_1, p_0)$ are the Coulomb integrals defined by Eqs. (7.46). For two p electrons Eq. (10.68) reduces to

$$E({}^3P) = \sum_{k=0,2} \left[a^k(p_1, p_0) F^k(np^2) - b^k(p_1, p_0) G^k(np^2) \right]. \tag{10.69}$$

Substituting the values for $a^k(p_1, p_0)$ and $b^k(p_1, p_0)$ for $k = 0, 2$ from Table 7.1 the electrostatic repulsion can be written as the sum of two F integrals (note that $F^k = G^k$ for equivalent electrons),

$$E({}^3P) = F_0 - 2F_2 - 3G_2 = F_0 - 5F_2. \tag{10.70}$$

In accordance with convention the common denominators of the a^k and b^k coefficients were eliminated by redefining the F integrals: $F_0 \equiv F^0$, $F_2 \equiv F^2/25$.

Also the ${}^1D$ term represents a stretched angular momentum state (orbital angular momentum in this case),

$$E({}^1D) = \langle \dot{1}, \bar{1}| \frac{1}{\rho_{12}} |\dot{1}, \bar{1}\rangle_{np^2}. \tag{10.71}$$

This case is even simpler than the ${}^3P$ term because the exchange term vanishes; as the orbital part is stretched it is manifestly symmetric - note also the antisymmetric spin part. Looking up $a^k(p_1, p_1)$ for $k = 0, 2$ from Table 7.1 the expression for the electrostatic repulsion takes the form

$$E({}^1D) = \sum_{k=0,2} a^k(p_1, p_1) F^k(np^2) = F_0 + F_2. \tag{10.72}$$

Note that $E({}^1D) > E({}^3P)$, in accordance with the first Hund rule.

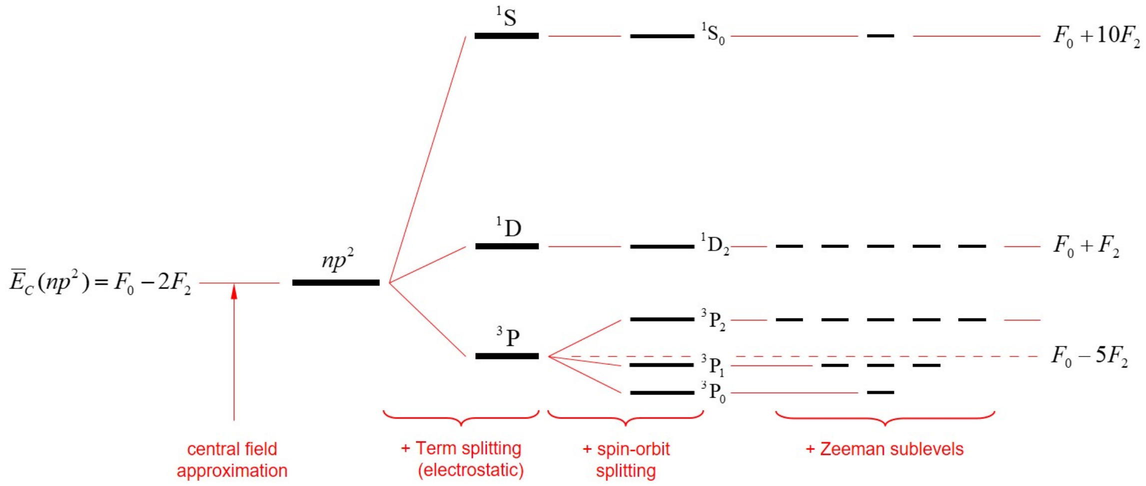

Figure 10.5: Fine-structure diagram of atoms from the carbon group (group 14) as an example of a np^2 valence configuration.

10.5.2.4 Slater sum rule

The electrostatic repulsion energy is more difficult to calculate for the ^1S term because it does not represent a stretched angular momentum state. In such cases the direct and exchange integrals do not suffice to calculate the energy with the straightforward way used above. Slater formulated a sum rule that enables to work around this complication. It is based on the invariance of the trace of the matrix of an operator $\mathcal{H}$ under a unitary transformation, $\mathcal{H}' = U^{-1}\mathcal{H}U$, from the coupled to the uncoupled representation,

$$\mathrm{tr}\,(\mathcal{H}') = \mathrm{tr}\,(U^{-1}\mathcal{H}U) = \mathrm{tr}\,(UU^{-1}\mathcal{H}) = \mathrm{tr}\,(\mathcal{H}). \tag{10.73}$$

This invariance follows from property (M.26) of square matrices. Secondly, the sum rule is based on the degeneracy of all magnetic sublevels M_S and M_L of a given LS term in zero field. Together with the states $|^3P;0,0\rangle$ and $|^1D;0,0\rangle$ the state $|^1S;0,0\rangle$ spans a 3 dimensional subspace. The electrostatic repulsion is diagonal in this basis and summing the diagonal matrix elements we obtain for the trace of the 3×3 matrix

$$\mathrm{tr}\,(3\times 3) = E(^3P) + E(^1D) + E(^1S) = 2F_0 - F_2 - 3G_2 + E(^1S), \tag{10.74}$$

where we used the M_S and M_L independence of the LS term energies. The same subspace is spanned by the determinantal states $|\dot{0},\bar{0}\rangle_{np^2}$, $|\dot{1},-\bar{1}\rangle_{np^2}$ and $|\bar{1},-\dot{1}\rangle_{np^2}$. The trace of the corresponding matrix is given by[1]

$$\begin{aligned}\mathrm{tr}\,(3\times 3) &= \langle\dot{0},\bar{0}|\frac{1}{\rho_{12}}|\dot{0},\bar{0}\rangle_{np^2} + \langle\dot{1},-\bar{1}|\frac{1}{\rho_{12}}|\dot{1},-\bar{1}\rangle_{np^2} + \langle\bar{1},-\dot{1}|\frac{1}{\rho_{12}}|\bar{1},-\dot{1}\rangle_{np^2}\\ &= (F_0+4F_2) + (F_0+F_2) + (F_0+F_2) = 3F_0 + 6F_2. \end{aligned}\tag{10.75}$$

Here the three matrix elements were calculated by looking up the a^k terms with the aid of Table 7.1. Comparing Eqs. (10.74) and (10.75), we find

$$E(^1S) = F_0 + 7F_2 + 3G_2 = F_0 + 10F_2. \tag{10.76}$$

Note that $E(^1S) > E(^3P)$, again in accordance with the first Hund rule.

---

[1] For diagonal matrix elements of the type $\langle\dot{u},\bar{v}|\rho_{12}^{-1}|\dot{u},\bar{v}\rangle$ the exchange terms do not contribute - see Problems 9.2 and 9.5.

10.5.3 Partially filled shells with nd^2 configuration

As a second example of a partially filled shell we consider the nd^2 configuration. This is the case of Ti, Zr, Hf and Rf. In the absence of the Pauli principle the electronic pair state $|\psi_{12}\rangle$ can be expressed as a linear combination of the $(2l+1)^2(2s+1)^2 = 100$ basis states of the *uncoupled* representation $\{|nlm_{l_1}sm_{s_1}\rangle \otimes |nlm_{l_2}sm_{s_2}\rangle\}$, with $l = 2$ and $s = \frac{1}{2}$. In this case we obtain

$$\binom{10}{2} = 45 \tag{10.77}$$

linearly independent antisymmetric states consistent with the Pauli principle. In Table 10.6 they are grouped by the values of $M_L = m_{l_1} + m_{l_2}$ and $M_S = m_{s_1} + m_{s_2}$.

Like in the case of the np^2 configuration we proceed by analyzing the nd^2 configuration in the *coupled representation* of the total orbital angular momentum $\mathbf{L} = \boldsymbol{l}_1 + \boldsymbol{l}_2$ coupled with the total spin $\mathbf{S} = \boldsymbol{s}_1 + \boldsymbol{s}_2$ into the total angular momentum $\mathbf{J} = \mathbf{L} + \mathbf{S}$. In a potential field of central symmetry J is a good quantum number. For the nd^2 configuration the orbital angular quantum number can take the values $L = 0, 1, 2, 3, 4$ with possible spin $S = 0, 1$. In the coupled representation $\{|JM_J\rangle\}$ again a total of 100 atomic states can be identified. In the LS-term notation these 100 states are also given in Table 10.6.

10.5.3.1 Determination of LS terms consistent with Pauli principle

Next we have to select the LS terms consistent with the Pauli principle. We start again with the terms of the highest multiplicity; i.e., with ${}^3G$. Since $L = 4$ and $S = 1$ the ${}^3G$ manifold must include the Slater determinant $|\dot{2},\dot{2}\rangle$, which corresponds to $M_L = 4$ and $M_S = 1$. But this determinant violates the Pauli principle and therefore has to be excluded. Continuing with the triplet manifolds, we turn to the ${}^3F$ terms, where $L = 3$ and $S = 1$. Therefore, the ${}^3F$ manifold must include the Slater determinant $|2, 1\rangle$, which corresponds to $M_L = 3$ and $M_S = 1$. Because this

Table 10.7: Decision table using the known LS-term degeneracy to determine the spin-orbit Terms consistent with the Pauli principle for two equivalent d-electrons .

†The sliced-arrow notation has no significance other than being compact.

determinant is consistent with the Pauli principle it must be within the fully anti-symmetric part of the Hilbert space. Further, because the ^3F terms represent a 21-fold degenerate manifold, also 21 linearly independent determinants are required to represent the ^3F sector of Hilbert space for all combinations of $M_S = 1, 0, -1$ and $M_L = 2, 1, 0, -1, -2$.

In Table 10.7 the determinants are assigned. Next we proceed with the ^3D term, where $L = 2$ and $S = 1$. It has to be excluded because there is only one linearly independent Slater determinant with $M_S = 1$ and $M_L = 2$ consistent with the Pauli principle and this one has to be assigned to the ^3F manifold. The next manifold is ^3P, which can be accepted because it must include the Slater determinant $|\dot{1}, \dot{0}\rangle$ and we have two determinants with $M_S = 1$ and $M_L = 1$ consistent with the Pauli principle, one was already assigned to the ^3F manifold, but the other serves our purpose. To represent the full ^3P manifold 9 linearly independent determinants are required. The ^3S has to be excluded because only two Slater determinants with $M_S = 1$ and $M_L = 0$ are consistent with the Pauli principle and these have to be assigned to the ^3F and the ^3P manifolds. We proceed by turning to the singlet manifolds, first the ^1G term ($L = 4; S = 0$). This 9-fold degenerate manifold must include the Slater determinant $|\dot{2}, \bar{2}\rangle$, which is allowed by the Pauli principle. Thus the ^1G sector must be part of the anti-symmetric part of Hilbert space spanned by 9 linearly independent Slater determinants corresponding to all combinations of $M_S = 0$ and $M_L = 2, 1, 0, -1, -2$. This procedure is continued until we decided on all LS terms. As illustrated in Table 10.7 only the terms $^3F_{4,3,2}$, $^3P_{2,1,0}$, $^1G_4$, $^1D_2$ and $^1S_0$ are consistent with the Pauli principle. Adding their degeneracies we recover the 45-dimensional Hilbert space of antisymmetric states identified above.

10.5.3.2 The second Hund rule

The relative energies of the LS terms of the nd^2 configuration may be estimated using the guidelines given for the np^2 configuration. All terms identified in Table 10.3 have the same energy in the screened Coulomb field of the nucleus

$$E_c(nd^2) = -2 \times hcR_\infty Z_{nd}^2/n^2, \tag{10.78}$$

where Z_{nd} is to be determined experimentally, or theoretically by numerical integration of the radial Schrödinger equation for a d-electron ($l = 2$) in the screened Coulomb field of the nucleus. The electrostatic repulsion between the electrons is lowest for the state with the largest average

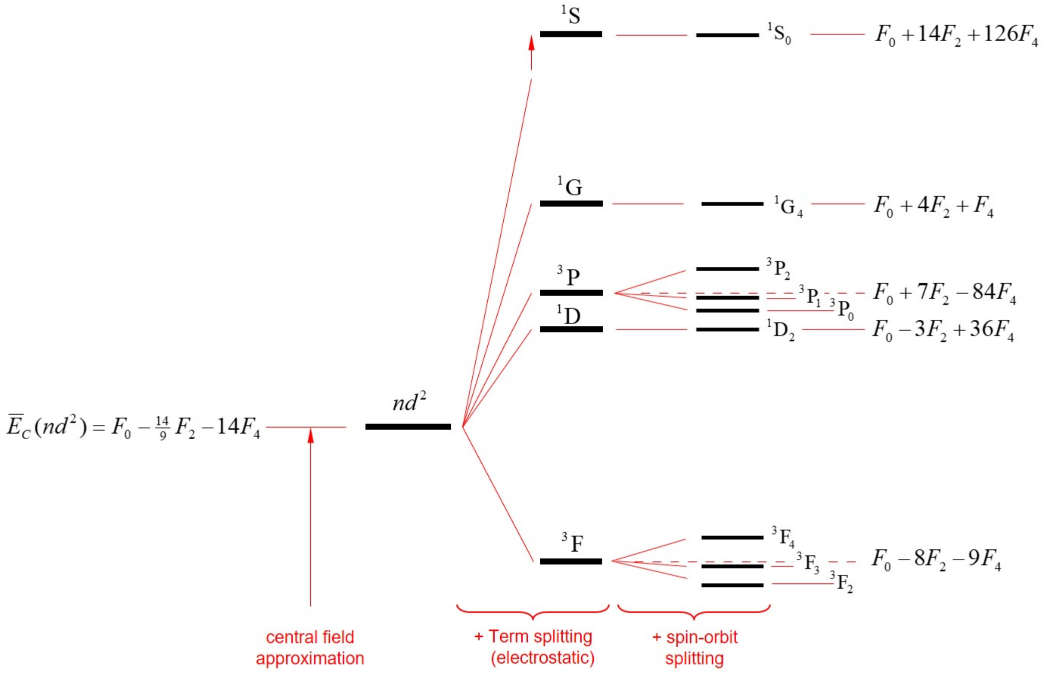

Figure 10.6: Fine-structure diagram of atoms from the titanium group (group 4) as an example of a nd^2 valence configuration.

separation. In view of Pauli exclusion of close approach this is the case for terms of maximum S (*Hund's first rule*).

The decision procedure of Table 10.7 resulted for the nd^2 configuration in *two* terms with $S = 1$: ^3F and ^3P. These terms differ in the coupling of the orbital angular momenta of the d electrons, parallel for the $^3F_{4,3,2}$ terms and antiparallel for the $^3P_{2,1,0}$ terms. If the angular momenta are in the same direction the electrons meet less than if they rotate in opposite direction. Therefore, the electrostatic repulsion is less in the state of maximum L. This exposes the physics behind the *second Hund rule*:

> The *Coulomb repulsion* between the valence electrons of an atomic ground state configuration (of maximal Pauli-allowed S) is *minimal for the maximal (Pauli-allowed) value of the total orbital angular momentum*, L.

Thus, the symmetric spin state with the largest angular momentum has the lowest energy. For the nd^2 configuration this corresponds to one of the triplet terms $^3F_{4,3,2}$. The ground state of Ti is indeed a ^3F term: $^3F_2$ (cf. Appendix C). To decide among the terms $^3F_4$, $^3F_3$ and $^3F_2$ we need *Hund's third rule*, which will be discussed in Section 10.6.

Calculation of Term energies: To conclude this section we verify that also the second Hund rule is confirmed by explicit calculation of the energy. Because in zero field the energy is independent of the magnetic quantum numbers we calculate the energy starting from the stretched spin states with the largest L, which can be written as a single nonzero Slater determinant, $|^3F; 3, 1\rangle = |\dot{2}, \dot{1}\rangle_{nd^2}$. In Hartree atomic units the energy shift caused by electrostatic repulsion of this ^3F term is given by

$$E(^3F) = \langle \dot{2}, \dot{1}| \frac{1}{\rho_{12}} |\dot{2}, \dot{1}\rangle_{nd^2}. \tag{10.79}$$

This is a diagonal matrix element of a two-body operator and using Eq. (9.52) we find

$$E(^3F) = (d2, d1|\rho_{12}^{-1}|d2, d1) - (d1, d2|\rho_{12}^{-1}|d2, d1) = \mathcal{J} - \mathcal{K}, \tag{10.80}$$

where $\mathcal{J} = (d2, d1|\rho_{12}^{-1}|d2, d1)$ and $\mathcal{K} = (d1, d2|\rho_{12}^{-1}|d2, d1)$ are the Coulomb integrals defined by Eqs. (7.46). As we are dealing with equivalent electrons we have $F^k = G^k$ and Eq. (10.79) reduces to

$$E(^3F) = \sum_{k=0,2,4} \left[a^k(d2, d1) F^k(nd^2) - b^k(d2, d1) G^k(nd^2) \right]. \tag{10.81}$$

Substituting the values for $a^k(d2, d1)$ and $b^k(d2, d1)$ for $k = 0, 2, 4$ from Table 7.1 the electrostatic repulsion can be written as the sum of three F integrals (note that $F^k = G^k$ for equivalent electrons),

$$E(^3F) = F_0 - 2F_2 - 4F_4 - 6G_2 - 5G_4 = F_0 - 8F_2 - 9F_4. \tag{10.82}$$

Here, the common denominators of the a^k and b^k coefficients where eliminated by redefining the F integrals: $F_0 \equiv F^0$, $F_2 \equiv F^2/49$ and $F_4 \equiv F^4/441$. The $|^3P; 1, 1\rangle$ term cannot be written as a single determinant. Thus we turn to the Slater sum rule and using the degeneracy of all magnetic sublevels M_S and M_L of a given LS term in zero field we obtain

$$\left.\begin{aligned} \mathrm{tr}\,(2 \times 2) &= E(^3F) + E(^3P) = F_0 - 8F_2 - 9F_4 + E(^3P) \\ \mathrm{tr}\,(2 \times 2) &= \langle \dot{2}, -\dot{1}|\rho_{12}^{-1}|\dot{2}, -\dot{1}\rangle_{nd^2} + \langle \dot{1}, \dot{0}|\rho_{12}^{-1}|\dot{1}, \dot{0}\rangle_{nd^2} = 2F_0 - F_2 - 93F_4 \end{aligned}\right\} \rightarrow$$

$$\rightarrow E(^3P) = F_0 + 7F_2 - 84F_4. \tag{10.83}$$

Thus $E(^3P) - E(^3F) = 15F_2 - 75F_4$ and the second Hund rule is satisfied if

$$E(^3P) > E(^3F) \Leftrightarrow 5F_4/F_2 = (245/441)\, F^4/F^2 < 1. \tag{10.84}$$

This is the case because $F^4 < F^2$ for a given screened potential - see Eq. (7.69).

10.5.4 Metastable excited state configurations

Before proceeding to the Hund's rule 3 we first have a look at some examples of excited states. Although the focus of the present chapter is on the determination of the electronic ground states the general formalism introduced in Chapter 9 can be applied to calculate the LS term energies of any electron configuration; i.e., also the energies of excited state configurations. In this section we shall demonstrate this for the $nsn's$ and $nsn'p$ configurations. In this way we can practice the procedure of Section 10.5 to calculate the Coulomb integrals for many-electron configurations. Thus, we consider the low-lying states of helium-like atoms; in particular, the $^1S_0$ and $^3S_1$ states of helium and the $^1P_1$ and $^3P_{0,1,2}$ states of the alkaline-earth atoms. The triplets terms are of special significance because they can represent metastable atomic states.

10.5.4.1 Metastable helium (He*)

Let us first convince ourselves that the general formalism leads to the same results as derived in Chapter 7 for the excited states of helium. The configuration of the ground state is $1s^2$. Exciting one of the $1s$ electrons to the $2s$ level we obtain the $1s2s$ configuration, which is compatible with $^1S_0$ (non-degenerate) and $^3S_1$ (three-fold degenerate) angular momentum terms, which are both Pauli allowed (because the electrons are non-equivalent). To calculate the electrostatic repulsion energy we turn to the uncoupled representation for which the $1s2s$ subspace can represented by the Slater determinants given in Table 10.8. As all $^3S_1$ levels are degenerate we can calculate the electrostatic repulsion energy in the $^3S_1$ term by by choosing the determinant of the spin-stretched state,

$$E(^3S) = \langle 1\dot{s}, 2\dot{s}|\rho_{12}^{-1}|1\dot{s}, 2\dot{s}\rangle = F_0 - G_0, \tag{10.85}$$

Table 10.8: Example $nsn's$ configuration: (top) uncoupled representation - the 4 linearly independent pair states consistent with the Pauli principle; (bottom) coupled representation.

$nsn's$		M_S			deg.
uncoupled		1	0	-1	
M_L	0	$\lvert n\dot{s}, n'\dot{s}\rangle$	$\lvert n\dot{s}, n'\bar{s}\rangle$ $\lvert n\bar{s}, n'\dot{s}\rangle$	$\lvert n\bar{s}, n'\bar{s}\rangle$	4

$\lvert {}^{2S+1}L; M_L, M_S\rangle$		M_S			deg.
coupled		1	0	-1	
M_L	0	$\lvert {}^3S; 1, 0\rangle$	$\lvert {}^3S; 0, 0\rangle$ $\lvert {}^1S; 0, 0\rangle$	$\lvert {}^3S; -1, 0\rangle$	4

with $F_0 = F^0$ and $G_0 = G^0/3$. The electrostatic repulsion energy in the ${}^1S_0$ term follows most conveniently with the Slater sum rule,

$$E({}^3S) + E({}^1S) = \mathrm{tr}\,(2 \times 2) = \langle 1\dot{s}, 2\bar{s}|\rho_{12}^{-1}|1\dot{s}, 2\bar{s}\rangle + \langle 1\bar{s}, 2\dot{s}|\rho_{12}^{-1}|1\bar{s}, 2\dot{s}\rangle = 2F_0. \tag{10.86}$$

Thus, the electrostatic repulsion energy in the ${}^1S_0$ term is

$$E({}^1S) = \mathrm{tr}\,(2 \times 2) - E({}^3S) = F_0 + G_0. \tag{10.87}$$

Comparing this result with the result of Section 7.3 we identify $\mathcal{J} = F_0$ and $\mathcal{K} = G_0$ (see Fig. 7.4). The average energy of the ${}^1S_0$ - ${}^3S_1$ manifold is

$$\bar{E}(1s, 2s) = [3(F_0 - G_0) + (F_0 + G_0)]/4 = F_0 - G_0/2. \tag{10.88}$$

10.5.4.2 Alkaline earth elements - lowest energy P manifolds

To discuss the low-lying excited states of the alkaline-earth elements we consider in particular the group 2 atoms, which all have a ground state configuration [inertgas]ns^2. The lowest-exited state configuration is [inertgas]$nsnp$, which is compatible with ${}^1P_1$ (three-fold degenerate) and ${}^3P_{0,1,2}$ (nine-fold degenerate) angular momentum terms, which are all Pauli allowed. The calculation of the term energies goes analogously to the case of helium. First we do the decomposition into Slater determinants, see Table 10.9. As all ${}^3P$ levels are degenerate we can calculate the electrostatic repulsion energy in the ${}^3P$ term by choosing the determinant of the fully stretched (spin and orbit) state,

$$E({}^3P) = \langle n\dot{s}, n\dot{p}_1|\rho_{12}^{-1}|n\dot{s}, n\dot{p}_1\rangle = F_0 - G_1, \tag{10.89}$$

with $F_0 = F^0$ and $G_1 = G^1/3$. Using the Slater sum rule,

$$E({}^3P) + E({}^1P) = \mathrm{tr}\,(2 \times 2) = \langle n\dot{s}, n\bar{p}_0|\rho_{12}^{-1}|n\dot{s}, n\bar{p}_0\rangle + \langle n\bar{s}, n\dot{p}_0|\rho_{12}^{-1}|n\bar{s}, n\dot{p}_0\rangle = 2F_0, \tag{10.90}$$

Table 10.9: Example $nsnp$ configuration: in the uncoupled representation we have 12 linearly independent pair states, all consistent with the Pauli principle

$nsnp$		M_S			deg.
uncoupled		1	0	-1	12
M_L	1	$\lvert n\dot{s}, n\dot{p}_1\rangle$	$\lvert n\dot{s}, n\bar{p}_1\rangle$ $\lvert n\bar{s}, n\dot{p}_1\rangle$	$\lvert n\bar{s}, n\bar{p}_1\rangle$	4
	0	$\lvert n\dot{s}, n\dot{p}_0\rangle$	$\lvert n\dot{s}, n\bar{p}_0\rangle$ $\lvert n\bar{s}, n\dot{p}_0\rangle$	$\lvert n\bar{s}, n\bar{p}_0\rangle$	4
	-1	$\lvert n\dot{s}, n\dot{p}_{-1}\rangle$	$\lvert n\dot{s}, n\bar{p}_{-1}\rangle$ $\lvert n\bar{s}, n\dot{p}_{-1}\rangle$	$\lvert n\bar{s}, n\bar{p}_{-1}\rangle$	4

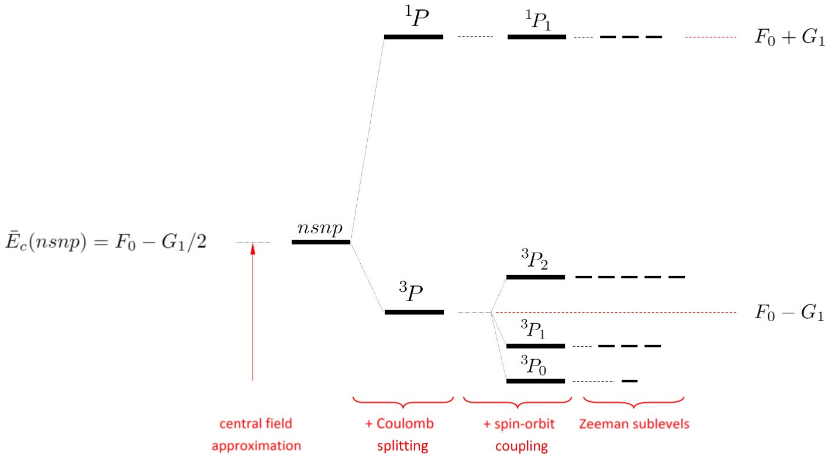

Figure 10.7: Coulomb splitting of $nsnp$ excited-state configuration of the alkaline-earth atoms (compare with Fig. 7.8).

we find for the electrostatic repulsion in the ^1S term

$$E(^1P)=\mathrm{tr}\,(2\times 2)-E(^3P)=F_0+G_1. \qquad (10.91)$$

Hence, the structure of the shift diagram is like that of metastable helium but the exchange integral is a different one, G_1 rather than G_0 (see Fig. 10.7). The average energy of the $^1P_1$ - $^3P_{0,1,2}$ manifold is

$$\bar{E}(n\dot{p},n\dot{s})=[9(F_0-G_1)+3(F_0+G_1)]/12=F_0-G_1/2. \qquad (10.92)$$

Since the Coulomb splitting is $2G_1$, the value of G_1 can be readily determined by atomic spectroscopy. From the data used for the level diagram 7.8 we can immediately determine the exchange integrals for the alkaline earth elements: Be: $G_1(2s,2p)=1.28$ eV, Mg: $G_1(3s,3p)=0.82$ eV, Ca: $G_1(4s,4p)=0.52$ eV, Sr: $G_1(5s,5p)=0.43$ eV, Ba: $G_1(6s,6p)=0.31$ eV. Note that the value drops by a factor 4 along the series which reflects the decreasing importance of the electrostatic interaction between the outer orbitals for growing atomic size (see also Table 10.10).

Problem 10.3. Show that the central field contribution to the electrostatic energy of the $1s^22s2p$ excited state configuration of *beryllium* (see Fig. 10.7) is given by

$$\begin{aligned}\bar{E}_c(1s^22s2p)=2I(1s)+I(2s)+I(2p)+F_0(1s,1s)+2F_0(2s,1s)-G_0(2s,1s)\\ +2F_0(2p,1s)-G_1(2p,1s)+\bar{E}(2p,2s).\end{aligned}$$

Solution. The energy of the $1s^22s2p$ excited state configuration of *beryllium* can be written as

$$\bar{E}_c(1s^22s2p)=2I(1s)+I(2s)+I(2p)+E_{1s^2}+E_{1s^2}(2s)+E_{1s^2}(2p)+\bar{E}(2p,2s),$$

where $\bar{E}(n\dot{p},n\dot{s})$ is energy average (10.92). Further we have $E_{1s^2}=F_0(1s^2)$, $E_{1s^2}(2s)=2F_0(2s,1s)-G_0(2s,1s)$ and $E_{1s^2}(2p)=2F_0(2p,1s)-G_1(2p,1s)$, where $F_0=F^0$, $G_0=G^0$ and $G_1=G^1/3$. Collecting the terms we obtain the desired expression. □

10.6 Fine structure - Hund's rule 3

10.6.1 Zeeman interaction

The Zeeman Hamiltonian of a many-electron atom is given by the sum of the Zeeman contributions of the individual electrons,

$$\mathcal{H}_Z=\sum\nolimits_i[g_L(e/2m_e)\boldsymbol{l}_i+g_e(e/2m_e)\boldsymbol{s}_i]\cdot\mathbf{B}, \qquad (10.93)$$

where $g_L \simeq 1$ is the effective g factor of the orbital motion and $g_e \simeq 2$ the anomalous g factor of the electron spin. In the absence of spin-orbit coupling the total orbital and spin angular momenta

$$\mathbf{L} = \sum_i \boldsymbol{l}_i \quad \text{and} \quad \mathbf{S} = \sum_i \boldsymbol{s}_i \tag{10.94}$$

are conserved quantities. Using the definition of the *Bohr magneton* $\mu_B = e\hbar/2m_e = 9.274\,0154(31)\times 10^{-24}$ J/T the Zeeman Hamiltonian can be written in the form

$$\mathcal{H}_Z = [g_L\mu_B\,(\mathbf{L}/\hbar) + g_e\mu_B\,(\mathbf{S}/\hbar)]\cdot\mathbf{B}. \tag{10.95}$$

Choosing the quantization axis (z axis) along the magnetic field direction this expression becomes

$$\mathcal{H}_Z = [g_L L_z + g_e S_z]\mu_B B/\hbar. \tag{10.96}$$

This Hamiltonian is diagonal in the uncoupled representation $\{|nLM_LSM_S\rangle\}$. The Zeeman shift is given by

$$\Delta E_Z = \langle nLM_LSM_S|\mathcal{H}_Z|nLM_LSM_S\rangle = [g_L M_L + g_e M_S]\mu_B B. \tag{10.97}$$

10.6.2 Spin-orbit interaction

In this section we return to spin-orbit coupling, introduced in Section 4.4 for hydrogen-like atoms. Now it is our task is to generalize this subject to the case of many-electron atoms. The analysis starts with the presence of a velocity-induced magnetic field whenever a particles is moving transversely to an electric field. In particular, electrons orbiting at velocity $\mathbf{v}$ in the electric field $\mathbf{E}$ of the partially shielded nucleus experience such a velocity-induced magnetic field, $\mathbf{B} = (\mathbf{E}\times\mathbf{v})/c^2$, where c is the speed of light (cf. Appendix E). The *spin-orbit coupling* is the coupling of the spin magnetic moment of the electron to this magnetic field. In the central-field approximation the electric field at the position of the electron is given by

$$\mathbf{E} = -\boldsymbol{\nabla}\varphi_{\mathrm{CF}}(r) = -\frac{\mathbf{r}}{r}\frac{d\varphi_{\mathrm{CF}}(r)}{dr}, \tag{10.98}$$

where $\varphi_{\mathrm{CF}}(r)$ is the central-field scalar potential. Including the *Thomas precession* the spin-orbit field takes the form

$$\mathbf{B}_{LS} \simeq -\frac{1}{2m_ec^2}\frac{1}{r}\frac{d\varphi_{\mathrm{CF}}(r)}{dr}\boldsymbol{l}, \tag{10.99}$$

where $\boldsymbol{l} = m_e(\mathbf{r}\times\mathbf{v})$ is the orbital angular momentum operator of the electron. The Hamiltonian describing the *spin-orbit interaction* of an individual electron is

$$\mathcal{H}_{ls} = g_e(e/2m_e)\boldsymbol{s}\cdot\mathbf{B}_{LS} = \xi(r)\boldsymbol{l}\cdot\boldsymbol{s}. \tag{10.100}$$

The function $\xi(r)$ is the *coupling strength*,

$$\xi(r) \simeq -\frac{1}{2m_e^2c^2}\frac{e}{r}\frac{d\varphi_{\mathrm{CF}}(r)}{dr}. \tag{10.101}$$

As long as the screened Coulomb potential, $\varphi_{\mathrm{CF}}(r)$, is a monotonically decreasing function of r, the coupling strength has to be positive,

$$\xi(\rho) \simeq -\frac{1}{2m_e^2c^2}\frac{e^2}{a^2}\frac{1}{\rho}\frac{d[Z_{\mathrm{scr}}(\rho)/\rho]}{d\rho} \equiv \frac{1}{2m_e^2c^2}\frac{e^2}{a^3}\frac{Z(\rho)}{\rho^3} > 0\,, \tag{10.102}$$

where $Z(\rho) \equiv Z_{\mathrm{scr}}(\rho) - \rho dZ_{\mathrm{scr}}(\rho)/d\rho$ is the spin-orbit screening function introduced in Section 4.4.2.

Summing the contributions of individual electrons we arrive at the Hamiltonian for the total spin-orbit interaction of the atom

$$\mathcal{H}_{LS} = \sum_{i=1}^{N}\xi_i(r)\boldsymbol{l}_i\cdot\boldsymbol{s}_i, \tag{10.103}$$

where $i \in \{1,\cdots N\}$ is the particle index of a system of N electrons.

10.6.3 Coupling schemes: LS coupling versus jj coupling

Adding the spin-orbit interaction to the central field Hamiltonian (8.3) we obtain the Hamiltonian

$$\mathcal{H} = \mathcal{H}_{\mathrm{CF}} + \mathcal{H}_{LS},$$

which suffices to calculate the ground states of most many-electron atoms. Recalling that closed subshells of equivalent electrons contribute zero angular momentum to the atom, the spin-orbit contribution can be calculated by restricting the particle-index summation in Eq. (10.103) to the valence electrons. In one-electron atoms this is particularly simple. The spin-orbit coupling results from the coupling of the spin $\boldsymbol{s}$ of the only valence electron with its own orbital angular momentum, $\boldsymbol{l}$. In Section 4.5.3 we found that the strength of this coupling scales with Z^4 for hydrogenic atoms in the weakly relativistic limit; for the alkalies we found it to increase by more than three orders of magnitude (in spite of the screening) when comparing *cesium* with *lithium* (see Section 4.6, in particular Table 4.3). It is straightforward to extend this analysis to one-electron atoms with one p electron (group III) or one d electron (group 3) in the ground state. Matters change when turning to two-electron atoms, two p electrons (group IV) or two d electrons (group 4) or to three-electron atoms, three d electrons (group 5) or three f electrons (*praseodymium*). In these cases not only the coupling strength but also the coupling scheme depends on Z but, whatever the coupling scheme, the total electronic angular momentum $\mathbf{J}$ is conserved (neglecting hyperfine structure).

- For small Z the electrostatic splitting between the LS terms is larger than the fine-structure splitting within the terms. In this case the various $\boldsymbol{l}_i$ couple into a total orbital angular momentum $\mathbf{L}$ and the $\boldsymbol{s}_i$ into a total spin $\mathbf{S}$, and these couple into the total electronic angular momentum
$$\mathbf{J} = \mathbf{L} + \mathbf{S}. \tag{10.104}$$
This coupling is known as LS coupling or *Russell-Saunders coupling.* In the presence of strong Russell-Saunders coupling the degeneracy of the LS terms is lifted by the spin-orbit interaction into levels differing in J. As long as this splitting remains small it can be calculated by perturbation theory with respect to the desired LS term. The Russell-Saunders coupling scheme applies typically to the atoms in the upper part of the periodic system.

- For large Z the spin-orbit interaction of the individual electrons dominates over the electrostatic coupling. This gives rise to a primary coupling into total angular momenta of the individual electrons, $\boldsymbol{j}_i = \boldsymbol{l}_i + \boldsymbol{s}_i$, and a subsequent coupling into the total electronic angular momentum of the atom,
$$\mathbf{J} = \sum_i \boldsymbol{j}_i.$$
This coupling scheme is known as jj coupling. The jj coupled levels differ in spin-orbit coupling energy. As long as the electrostatic interaction energy is small as compared to the splitting of the J levels it can be calculated by perturbation theory with respect to the jj coupled level. This coupling tends to reduce the spin-orbit splitting until the Russell-Saunders limit is reached in which all J levels are degenerate. The jj coupling scheme applies to the heaviest atoms of the periodic table.

- For the middle part of the periodic system the coupling is said to be *intermediate* between LS and jj coupling.

10.6.4 Russell-Saunders coupling

In this course we mostly restrict ourselves to LS coupling and calculate the spin-orbit shift in the *coupled representation* with first-order perturbation theory. This is allowed as long as the spin-orbit splitting is much smaller than the LS-term splitting. This approximation is valid except in cases of *configuration interaction.* For a given LS term, $|LSJM_J\rangle$, the *spin-orbit shift* is given by

$$\Delta E_{n,J}^{LS} = \langle nLSJM_J|\mathcal{H}_{LS}|nLSJM_J\rangle, \tag{10.105}$$

where it remains to be shown that the matrix is diagonal. Decomposing the LS term to the *uncoupled representation* we obtain

$$\Delta E_{n,J}^{LS} = \sum_{M_L,M_L'}\sum_{M_S,M_S'} \langle nLSJM_J|nLM_L'SM_S'\rangle \\ \langle nLM_L'SM_S'|\mathcal{H}_{LS}|nLM_LSM_S\rangle\langle nLM_LSM_S|nLSJM_J\rangle. \tag{10.106}$$

Because the operators $\boldsymbol{l}_i$ operate on the orbital states and $\boldsymbol{s}_i$ on the spin states we can factor out the spin part from the orbital part, and the matrix elements take the form

$$\langle nLM_L'SM_S'|\mathcal{H}_{LS}|nLM_LSM_S\rangle = \sum_i \langle nLM_L'SM_S'|\xi_i(r)\boldsymbol{l}_i\cdot\boldsymbol{s}_i|nLM_LSM_S\rangle \tag{10.107}$$

$$= (\zeta_{nl}/\hbar^2)\sum_i \langle LM_L'|\boldsymbol{l}_i|LM_L\rangle\cdot\langle SM_S'|\boldsymbol{s}_i|SM_S\rangle, \tag{10.108}$$

where the summation runs over all equivalent electrons in the partially filled shell and ζ_{nl} is the *spin-orbit coupling constant* of the electrons in the shell under consideration. Recalling the Wigner-Eckart theorem we know that the components of $\boldsymbol{l}_i$ and $\boldsymbol{s}_i$ are proportional to the corresponding components of $\mathbf{L}$ and $\mathbf{S}$,

$$\langle LM_L'|\boldsymbol{l}_i|LM_L\rangle = \langle L||l_i||L\rangle\langle LM_L'|\mathbf{L}|LM_L\rangle \tag{10.109a}$$

$$\langle SM_S'|\boldsymbol{s}_i|SM_S\rangle = \langle S||s_i||S\rangle\langle SM_S'|\mathbf{S}|SM_S\rangle. \tag{10.109b}$$

Introducing the *Russell-Saunders coupling constant*,

$$\zeta_{nLS} = \zeta_{nl}\sum_i \langle L||l_i||L\rangle\langle S||s_i||S\rangle, \tag{10.110}$$

the Russell-Saunders matrix element becomes

$$\langle nLM_L'SM_S'|\mathcal{H}_{LS}|nLM_LSM_S\rangle = \zeta_{nLS}/\hbar^2\langle LM_L'SM_S'|\mathbf{L}\cdot\mathbf{S}|LM_LSM_S\rangle. \tag{10.111}$$

With the aid of the projection theorem the reduced matrix element $\langle L||l_i||L\rangle$ can be written in the form

$$\langle L||l_i||L\rangle = \frac{\langle LM_L|\boldsymbol{l}_i\cdot\mathbf{L}|LM_L\rangle}{\langle LM_L|\mathbf{L}^2|LM_L\rangle}. \tag{10.112}$$

A similar expression for $\langle S||s_i||S\rangle$ follows analogously. Returning to Eq. (10.111) and substituting this expression into Eq. (10.106) we obtain (after transforming back to the *coupled representation*) the following expression for the spin-orbit shift

$$\Delta E_{n,J}^{LS} = \left(\zeta_{nLS}/\hbar^2\right)\langle LSJM_J|\mathbf{L}\cdot\mathbf{S}|LSJM_J\rangle. \tag{10.113}$$

Here we used the inner product rule (3.159a) to establish that, in Russell-Saunders coupling, the spin-orbit interaction is indeed *diagonal* in the coupled representation. For the spin-orbit shift we find,

$$\Delta E_{n,J}^{LS} = \tfrac{1}{2}\zeta_{nLS}\left[J(J+1) - L(L+1) - S(S+1)\right]. \tag{10.114}$$

For positive coupling constant ($\zeta_{nLS} > 0$) the LS term with the lowest J has the lowest energy. Likewise, for negative coupling constant ($\zeta_{nLS} < 0$) the lowest energy is obtained for the highest value of J. With Eq. (10.114) we have obtained for the case of many-electron atoms the same expression for the spin-orbit shift as derived in Chapter 4 for hydrogen-like atoms. In the present context this expression is valid for the case of LS coupling of arbitrary L and S.

Table 10.10: Fine-structure splitting ratio $\Delta W_2/\Delta W_1$ of ^3P terms for increasing value of Z. For pure Russell-Saunders coupling this ratio is 2. Deviations from this value point to the presence of other coupling mechanisms. In the absence of nuclear spin ($I = 0$) and for large Z this points to a crossover to jj-coupling. This is confirmed by comparing the decrease in Coulomb integral G_1 (see Section) with the increase in fine-structure splitting ΔW_1.

element	Be	Mg	Ca	Sr	Ba	Ra	unit
Z	4	12	20	38	56	88	
G_1	1.28	0.82	0.52	0.43	0.31	0.33	eV
ΔW_1	8×10^{-5}	0.002	0.006	0.023	0.046	0.114	eV
$\Delta W_2/\Delta W_1$	3.6357	2.0297	2.0298	2.1100	2.3695	2.9200	

10.6.4.1 Shift rules for Russell-Saunders coupled angular momenta

As introduced in Section 4.5.2 expressions of the type (10.114) imply *three shift rules* for the spin-orbit manifolds of given J, L and S:

- the shift of the *stretched state* ($J = J_{\max} = L + S$) is given by

$$\Delta E^{LS}_{n,J_{\max}} = \zeta_{nLS} LS. \tag{10.115}$$

- the relative shift of two adjacent LS-coupled manifolds follows the *Landé interval rule*:

$$\Delta W_J = \Delta E^{LS}_{n,J} - \Delta E^{LS}_{n,J-1} = \zeta_{nLS} J, \tag{10.116}$$

  where J is the quantum number of the manifold with the highest multiplicity *of the pair.*

- the weighted mean of the energies of *all manifolds* of a given LS coupling scheme satisfies the *center-of-gravity rule*:

$$\frac{1}{(2L+1)\,(2S+1)} \sum_{J=|L-S|}^{L+S} (2J+1)\,\Delta E^{LS}_{n,J} = 0, \tag{10.117}$$

  where $(2L+1)\,(2S+1)$ is the degeneracy of the unperturbed level.

The shift rules are illustrated for the case $L = 1$, $S = 1$ in Fig. 10.8. In the absence of hyperfine interaction ($I = 0$), breakdown of the interval rule is an indicator for the breakdown of pure LS coupling. For ^3P terms this shows up as a deviation of the pure LS splitting ratio $\Delta W_2/\Delta W_1 = 2$. In Table 10.10 this is illustrated for the Z dependence of $\Delta W_2/\Delta W_1$ for the lowest ^3P terms of the alkaline-earth elements (see also Fig. 7.8).

10.6.5 Equivalence of electrons and holes

Let us consider a closed nl shell and remove one of the electrons. This leaves us with a partially filled shell occupied by $2(2l+1) - 1$ electrons, total orbital angular momentum $\mathbf{L}$ and total spin $\mathbf{S}$. As closed shells have *zero* angular momentum, we know that the angular momenta of the partially filled shell and that of the vacant electron have to add up to zero, $\mathbf{L} + \boldsymbol{l} = 0$ and $\mathbf{S} + \boldsymbol{s} = 0$. In other words, the angular momenta of the partially filled shell are opposite to those of the electron removed,

$$\mathbf{L} = -\boldsymbol{l} \quad \text{and} \quad \mathbf{S} = -\boldsymbol{s}. \tag{10.118}$$

This simple result of what could have been a serious calculation (see Section 10.5) suggests to assign properties to a lacking electron. The configuration behaves like a closed shell in which an imaginary

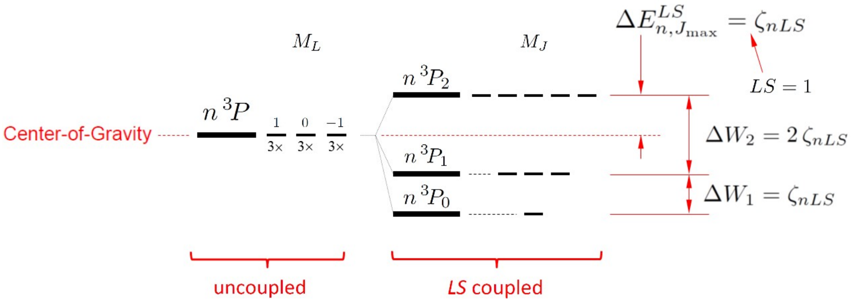

Figure 10.8: The shift rules for spin-orbit coupling in the Russell-Saunders limit plotted for the example $L = 1$, $S = 1$. Triplets of this type are observed in the ground state of low-Z group-12 atoms like *carbon* and in $ns \to np$ excited states of low-Z helium-like atoms like *calcium*.

particle, called the *hole*, cancels all properties of the electron filling the vacancy. So, rather than *removing* an electron from the shell we *add* a hole. The hole has to be always at the position of the vacancy filling electron (i.e., move at the same velocity) and have opposite charge ($q = +e$) and mass ($m_h = -m_e$). Apparently the hole has orbital angular momentum $\boldsymbol{l}_h \equiv \mathbf{L} = -\boldsymbol{l}$ and spin $\boldsymbol{s}_h \equiv \mathbf{S} = -\boldsymbol{s}$. In search for more properties of the hole we return to the nl shell with one vacancy. Rewriting Eq. (10.113) with the aid of Eq. (10.110) we obtain for the spin-orbit shift

$$\Delta E^{LS}_{n,J} = \zeta_{nl} \sum_{i=1}^{2(2l+1)-1} \langle L||l_i||L\rangle\langle S||s_i||S\rangle\langle nLSJM_J|\mathbf{L}\cdot\mathbf{S}|nLSJM_J\rangle, \tag{10.119}$$

Adding and subtracting the contribution of the lacking electron and using Eqs. (10.118) we find for the spin-orbit shift of a shell with a single hole

$$\Delta E^{LS}_{n,J} = -\left(\zeta_{nl}/\hbar^2\right)\langle nLSJM_J|\boldsymbol{l}\cdot\boldsymbol{s}|nLSJM_J\rangle = -\left(\zeta_{nl}/\hbar^2\right)\langle nLSJM_J|\mathbf{L}\cdot\mathbf{S}|nLSJM_J\rangle, \tag{10.120}$$

where

$$\zeta_{nl} = \langle nl||\xi(r)||nl\rangle\hbar^2 > 0 \tag{10.121}$$

is the spin-orbit coupling constant of a single nl electron moving in the shielded nuclear potential. Comparing Eqs. (10.120) and (10.113) we find

$$\zeta_{nLS} = -\zeta_{nl} = -\langle nl||\xi(r)||nl\rangle\hbar^2. \tag{10.122}$$

In view of Eq. (10.101) this expression represents the coupling constant of a single *positive* charge $q = +e$ moving in a nl orbital through the shielded field of the nuclear charge. For the intrinsic magnetic moment we require

$$\boldsymbol{\mu}_h = g_h(e/2m_h)\boldsymbol{s}_h = g_e(e/2m_e)\boldsymbol{s} = -\boldsymbol{\mu}_s, \tag{10.123}$$

which implies $g_h = g_e$. Since the electron and hole are at the same position $\mathbf{r}$ and move with the same velocity $\mathbf{v}$ (i.e., have opposite momentum) we find

$$\boldsymbol{l}_h = -\boldsymbol{l} = -m_e(\mathbf{r}\times\mathbf{v}) = m_h(\mathbf{r}\times\mathbf{v}). \tag{10.124}$$

10.6.6 Third Hund rule

Eq. (10.122) may be generalized to hold for the *ground state* of a partially filled shell of configuration nl^x. Let us suppose that we are interested in the Russell-Saunders coupling constant ζ_{nLS} of a given

LS term of this configuration. Since the coupling constant is independent of J we are free to select the most convenient J manifold to find a relation between ζ_{nLS} and ζ_{nl}. This turns out to be the manifold of the *stretched state*, $J = J_{\max} = L + S$, because in this case the shift rule is particularly simple - see Eq. (10.115),

$$\Delta E^{LS}_{n,J_{\max}} = \langle nLSJ_{\max}M_J|\mathcal{H}_{LS}|nLSJ_{\max}M_J\rangle = \zeta_{nLS}LS. \tag{10.125}$$

Moreover, this is the manifold which contains the pure state, which is the state with $M_J = J$. It is called *pure* because it maps uniquely onto the $M_L = L$, $M_S = S$ sublevel of the uncoupled representation (see Section 4.7.3). In other words, we can equally well calculate the matrix element

$$\Delta E^{LS}_{n,J_{\max}} = \langle nLLSS|\mathcal{H}_{LS}|nLLSS\rangle. \tag{10.126}$$

As this matrix element is diagonal we only have to evaluate the diagonal part of $\mathcal{H}_{LS}$ as is confirmed by the actual calculation,

$$\Delta E^{LS}_{n,J_{\max}} = \langle nLLSS|\zeta_{nLS}L_zS_z|nLLSS\rangle = \zeta_{nLS}LS. \tag{10.127}$$

Next we make the connection with the spin-orbit terms of the individual electrons. For the *ground state* we know that the first two Hund rules are satisfied. This means that the LS term of the ground state carries the largest values of S and L consistent with the Pauli principle. For such terms the subspace with $M_S = S$ and $M_L = L$ can be represented by a *single* Slater determinant (corresponding to the stretched electron - or hole - spin state)

$$|nLLSS\rangle = |m_l^1 m_s^1, \cdots m_l^N m_s^N\rangle_{nl}, \tag{10.128}$$

where

$$M_S = \sum_{\kappa=1}^{N} m_s^\kappa = S \quad \text{and} \quad M_L = \sum_{\kappa=1}^{N} m_l^\kappa = L. \tag{10.129}$$

In terms of the Slater determinants the spin-orbit shift takes the form

$$\begin{aligned}\Delta E^{LS}_{n,J_{\max}} &= \langle m_l^1 m_s^1, \cdots m_l^N m_s^N|\mathcal{H}_{LS}|m_l^1 m_s^1, \cdots m_l^N m_s^N\rangle_{nl} \\ &= \sum_{i=1}^{N}\langle m_l^1 m_s^1, \cdots m_l^N m_s^N|\xi_i(r)\boldsymbol{l}_i\cdot\boldsymbol{s}_i|m_l^1 m_s^1, \cdots m_l^N m_s^N\rangle_{nl}.\end{aligned} \tag{10.130}$$

Hence, we have to evaluate the diagonal matrix elements of the one-body operators $\xi_i(r)\boldsymbol{l}_i\cdot\boldsymbol{s}_i$. With the aid of Eq. (9.44) we obtain

$$\Delta E^{LS}_{n,J_{\max}} = \zeta_{nl}/\hbar^2\sum_{\kappa=1}^{N}\langle lm_l^\kappa sm_s^\kappa|\boldsymbol{l}\cdot\boldsymbol{s}|lm_l^\kappa sm_s^\kappa\rangle = \zeta_{nl}\sum_{\kappa=1}^{N} m_l^\kappa m_s^\kappa. \tag{10.131}$$

Comparing the expressions (10.125) and (10.131) we find the following expression for the coupling constant,

$$\zeta_{nLS} = \frac{\zeta_{nl}}{LS}\sum_{\kappa=1}^{N} m_l^\kappa m_s^\kappa. \tag{10.132}$$

At this point we distinguish between two cases:

a.) *Shells less than half full.* In this case we have $M_S = S = x/2$ (Hund's rule 1), $M_L = L$ (Hund's rule 2), with $m_s^\kappa = \frac{1}{2}$ for $\kappa \in \{1, \cdots N\}$. Substituting these quantum numbers into Eq. (10.132) we obtain

$$\zeta_{nLS} = \frac{1}{2}\frac{\zeta_{nl}}{LS}\sum_{\kappa=1}^{N} m_l^\kappa = \frac{1}{2}\frac{\zeta_{nl}}{LS}M_L = +\frac{\zeta_{nl}}{2S}. \tag{10.133}$$

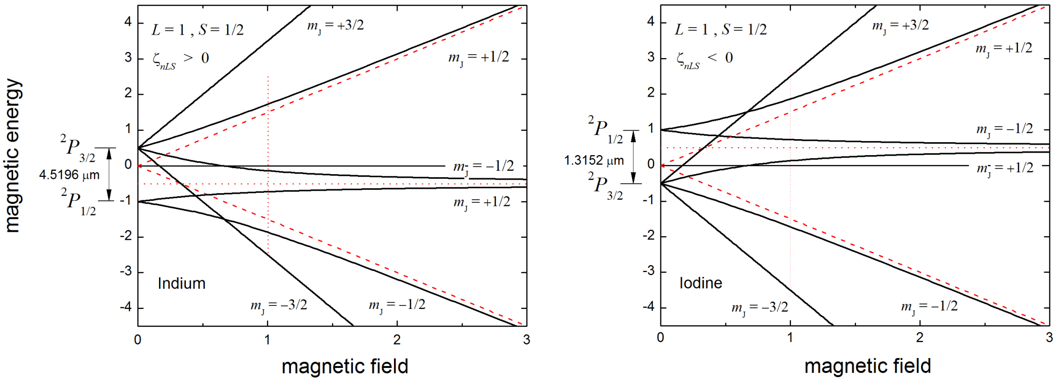

Figure 10.9: Magnetic energy versus magnetic field in units of the fine-structure field B_{fs}. Left: positive spin-orbit shift (one p electron - ground state of Indium). Right: negative spin-orbit shift (one p hole - ground state of Iodine).

b.) *Shells more than half full.* In this case we have $M_S = S = (2l+1) - x/2$ (Hund's rule 1), $M_L = L$ (Hund's rule 2), with $m_s^\kappa = \frac{1}{2}$ for $\kappa \in \{1, \cdots 2l+1\}$ and $m_s^\kappa = -\frac{1}{2}$ for $\kappa \in \{2l+2, \cdots N\}$

$$\zeta_{nLS} = \frac{1}{2}\frac{\zeta_{nl}}{LS}\sum_{\kappa=1}^{2l+1} m_l^\kappa - \frac{1}{2}\frac{\zeta_{nl}}{LS}\sum_{\kappa=2l+2}^{N} m_l^\kappa = -\frac{1}{2}\frac{\zeta_{nl}}{LS}M_L = -\frac{\zeta_{nl}}{2S}. \tag{10.134}$$

The first summation yields zero because $L = 0$ for half-filled shells. The second summation yields $M_L = L$.

Together with Eq. (10.114) the expressions (10.133) and (10.134) provide the scientific underpinning of the *third Hund rule*:

> The *most negative spin-orbit shift* is obtained for the valence electrons of an atomic ground state configuration (of maximal Pauli-allowed S and L) if the *total electronic angular momentum*, J, *is (a) minimal for less-than-half-filled shells*; *(b) maximal for more-than-half-filled shells.*

In Fig. 10.9 the two cases are illustrated by the ground-state fine-structure diagrams of Indium and Iodine. Note that the third Hund rule plays no role in the case of half-filled shells because in this case only a single J value ($J = S$) needs to be considered.

10.7 Zeeman effect in the presence of spin-orbit interaction

10.7.1 Hamiltonian

The Hamiltonian describing the fine-structure of many-electron atoms is given by

$$\mathcal{H} = \mathcal{H}_{\mathrm{CF}} + \mathcal{H}_{LS} + \mathcal{H}_Z, \tag{10.135}$$

where $\mathcal{H}_{\mathrm{CF}}$ is the central-field Hamiltonian (8.3), $\mathcal{H}_Z$ the Zeeman Hamiltonian (10.93) and $\mathcal{H}_{LS}$ the spin-orbit Hamiltonian (10.103). We write this as $\mathcal{H} = \mathcal{H}_0 + \mathcal{H}'$, where

$$\mathcal{H}' = \mathcal{H}_{LS} + \mathcal{H}_Z \tag{10.136}$$

is the perturbation to be considered. Because in weak magnetic fields $\langle\mathcal{H}'\rangle \ll \langle\mathcal{H}_{\mathrm{CF}}\rangle$ we look for a perturbative solution using perturbation theory for degenerate levels. The Hamiltonian $\mathcal{H}_{LS}$ is diagonal in the $\{|nLSJM_J\rangle\}$ (*coupled*) representation and $\mathcal{H}_Z$ in the $\{|nLM_LSM_S\rangle\}$ (*uncoupled*) representation. Physically, there is competition between the mutual coupling of **L** and **S** and the coupling of **L** and **S** individually with the external **B** field. In low fields the spin-orbit coupling is dominant, whereas in the high field limit it may be neglected. Thus, also for many electron atoms we have a *Paschen-Back effect.* In intermediate fields the Hamiltonian is neither diagonal in the coupled nor in the uncoupled representation and we have to solve the secular equation (I.24),

$$|\mathcal{H}'_{\mu,\nu} - W_n| = 0, \tag{10.137}$$

where $\mathcal{H}'_{\mu,\nu}$ are the matrix elements of the perturbation in the representation of choice. Note that the overlap integral in Eq. (I.24) vanishes when using orthonormal basis states.

10.7.2 Description in the uncoupled basis

To solve the secular equation in the *uncoupled* representation within a given LS term we use one of the inner product rules to write the perturbation in the form

$$\mathcal{H}' = \zeta_{nLS}\left[L_zS_z + \tfrac{1}{2}\left(L_+S_- + L_-S_+\right)\right] + (g_L\mu_BL_z + g_S\mu_BS_z)B/\hbar. \tag{10.138}$$

Note that this Hamiltonian conserves the total angular momentum along the z axis; i.e., $M_l + M_S$ is a "good" quantum number (J_z commutes with the Hamiltonian) for all values of the magnetic field. This quantum number will be denoted by M_J. The diagonal matrix elements for given values of $M_J = M_l + M_S$ are given by

$$\begin{aligned}\mathcal{H}'_{M_JM_SM_S} &= \langle L\,(M_J - M_S)\,SM_S|\zeta_{nLS}L_zS_z + (g_L\mu_BL_z + g_S\mu_BS_z)B/\hbar|L\,(M_J - M_S)\,SM_S\rangle\\ &= \zeta_{nLS}\,(M_J - M_S)\,M_S + [g_LM_J + (g_S - g_L)\,M_S]\,\mu_BB,\end{aligned} \tag{10.139}$$

where ζ_{nLS} is the spin-orbit energy given by Eq. (10.133) or (10.133). The off-diagonal elements are found using the shift operators (1.59) and the conservation of M_J,

$$\begin{aligned}\mathcal{H}'_{M_J(M_S\mp1)M_S} &= \tfrac{1}{2}\zeta_{nLS}\langle L\,(M_J - M_S \pm 1)\,S\,(M_S \mp 1)\,|L_\pm S_\mp|L\,(M_J - M_S)\,SM_S\rangle\\ &= \tfrac{1}{2}\zeta_{nLS}\sqrt{L\,(L+1) - (M_J - M_S)\,(M_J - M_S \pm 1)}\sqrt{S\,(S+1) - M_S(M_S \mp 1)}.\end{aligned} \tag{10.140}$$

As demonstrated in Section 4.7 for hydrogen-like atoms, the solution of the secular equation (10.137) can be obtained analytically for arbitrary magnetic fields because the electronic states are *electron spin doublets* $S = s = \frac{1}{2}$) and $J = j = l \pm \frac{1}{2}$. In this case, the characteristic equation is of the asymmetric type (*cf.* Appendix H.3) and factorizes into a product of two (1×1) and $l+1$ (2×2) determinants, each characterized by its own value of $M_J = M_l + M_S$. In Fig. 10.9 the magnetic field dependence based on these solutions is plotted for both positive and negative coupling constants.

For many-electron atoms the factorization of the secular equation into $(d\times d)$ determinants will in general also contain determinants with $d > 2$, for which the diagonalization is best done numerically with *Mathematica.* For the

10.7.3 High-field limit - Paschen-Back effect

In high magnetic fields the spin-orbit coupling is weak as compared to the Zeeman interaction. This is known as the Paschen-Back effect and best analyzed in the *uncoupled* representation $\{|nLM_LSM_S\rangle\}$ in which case the atomic Hamiltonian including the Zeeman interaction, $\mathcal{H}_0 + \mathcal{H}_Z$, is diagonal. In this basis the spin-orbit matrix elements are given by

$$\mathcal{H}^{LS}_{M_L'M_S';M_LM_S} = \zeta_{nLS}\langle LM_L'SM_S'|L_zS_z + \tfrac{1}{2}\left(L_+S_- + L_-S_+\right)|LM_LSM_S\rangle\,. \tag{10.141}$$

As only the diagonal matrix elements of a weak perturbation contribute to leading order in perturbation theory, in high fields the spin-orbit shift is given by $\Delta E^{LS}_{n;M_L M_S} = \zeta_{nLS} M_L M_S$ and the field dependence can be expressed as

$$\Delta E_{n;M_L M_S} = \zeta_{nLS} M_L M_S + (g_L M_L + g_S M_S)\,\mu_B B. \tag{10.142}$$

Note that this expression is valid for *arbitrary* values of L and S.

10.7.4 Low-field limit - Landé factor

For magnetic fields much lower than the fine-structure field ($B \ll B_{\text{fs}}$) the angular momenta $\mathbf{L}$ and $\mathbf{S}$ are coupled into the total electronic angular momentum $\mathbf{J} = \mathbf{L} + \mathbf{S}$. Under these conditions the atomic Hamiltonian

$$\mathcal{H} = (\mathcal{H}_{\text{CF}} + \mathcal{H}_{LS}) + \mathcal{H}_Z \tag{10.143}$$

is best analyzed in the *coupled* representation $\{|nLSJM_J\rangle\}$, where the first two terms of Eq. (10.143) are diagonal and $\mathcal{H}_Z$ acts as the perturbation. In this basis and for given values of n, L, S, J the perturbation gives rise to an energy shift

$$\Delta E^Z_{J,M_J} = \langle JM_J| g_L L_z + g_e S_z\,|JM_J\rangle\,\mu_B B/\hbar \tag{10.144}$$

Note that the operators L_Z and S_Z are diagonal in the $\{|nLSJM_J\rangle\}$ basis because they conserve M_L and M_S and, in view of the M_J *selection rule* (3.89), also $M_L + M_S = M_J$. Hence, in sufficiently low fields J and M_J are "good" quantum numbers for the atomic Hamiltonian (10.143).

Intuitively this situation is also clear: for sufficiently low fields the magnetic moment of the atom will scale with the total electronic angular momentum $\mathbf{J}$,

$$\boldsymbol{\mu}_J = -g_J \mu_B\,(\mathbf{J}/\hbar) \qquad \text{for } B \to 0. \tag{10.145}$$

Hence, the Zeeman energy can be described by the effective Hamiltonian $\mathcal{H}_Z = -\boldsymbol{\mu}_J \cdot \mathbf{B}$. This Hamiltonian yields a Zeeman shift on top of the zero-field spin-orbit shift ΔE^{LS}_{nJ} (for given values of n, L, S, J):

$$\Delta E^Z_{J,M_J} = g_J \mu_B B \langle Jm_J|(J_z/\hbar)\,|JM_J\rangle = g_J \mu_B M_J B \qquad \text{for } B \to 0. \tag{10.146}$$

As was to be expected, also this effective Hamiltonian is diagonal in the $\{|nLSJM_J\rangle\}$ basis if the quantization axis is chosen along the direction of the $\mathbf{B}$ field. Our task is of course to determine the value of g_J.

10.7.4.1 Wigner-Eckart theorem

To understand the relation between Eqs. (10.144) and (10.146) we recall the vector diagram in Fig. 4.6. The slow precession of $\mathbf{J} = \mathbf{L} + \mathbf{S}$ about the direction of a weak probe field (just serving to define a quantization axis) does not affect the projections of the angular momentum operators L_z, S_z and J_z. In other words these operators are invariant under rotation about the z axis. As all three are diagonal in the $\{|nLSJM_J\rangle\}$ basis, the matrix elements of L_z and S_z can be written in the form

$$\langle nLSJM_J|\, L_z\,|nLSJM_J\rangle = \langle lsJ\,\|L\|\,lsJ\rangle\,\langle JM_J|\,J_z\,|JM_J\rangle \tag{10.147a}$$

$$\langle nLSJM_J|\, S_z\,|nLSJM_J\rangle = \langle lsJ\,\|S\|\,lsJ\rangle\,\langle JM_J|\,J_z\,|JM_J\rangle\,, \tag{10.147b}$$

where the proportionality constants $\langle LSJ\,\|L\|\,LSJ\rangle$ and $\langle LSJ\,\|S\|\,LSJ\rangle$ are known as *reduced matrix elements* and are *independent of* M_J. Since $J_z = L_z + S_z$ we find by adding Eqs. (10.147a) and (10.147b) that the reduced matrix elements add up to unity,

$$\langle LSJ\,\|L\|\,LSJ\rangle + \langle LSJ\,\|S\|\,LSJ\rangle = 1 = \langle LSJ\,\|J\|\,LSJ\rangle. \tag{10.148}$$

The projections of $\mathbf{L}$ and $\mathbf{S}$ along the total angular momentum vector $\mathbf{J}$, i.e. $\mathbf{L}\cdot\mathbf{J}$ and $\mathbf{S}\cdot\mathbf{J}$, are conserved while $\mathbf{J}$ precesses about $\mathbf{B}$,

$$\langle nLSJM_J|\, L_z\, |nLSJM_J\rangle = \frac{\langle LSJM_J|\,(\mathbf{L}\cdot\mathbf{J})\, J_z\,|LSJM_J\rangle}{\langle LSJM_J|\,\mathbf{J}^2\,|LSJM_J\rangle}. \tag{10.149}$$

comparing with Eq. (10.147a) we find

$$\langle LSJ\, \|L\|\, LSJ\rangle = \frac{\langle LSJM_J|\,\mathbf{L}\cdot\mathbf{J}\,|LSJM_J\rangle}{\langle LSJM_J|\,\mathbf{J}^2\,|LSJM_J\rangle} = \frac{J(J+1)+L(L+1)-S(S+1)}{2J(J+1)}, \tag{10.150}$$

which is indeed independent of M_J. Analogously we find

$$\langle LSJ\, \|S\|\, LSJ\rangle = \frac{\langle LSJM_J|\,\mathbf{S}\cdot\mathbf{J}\,|LSJM_J\rangle}{\langle LSJM_J|\,\mathbf{J}^2\,|LSJM_J\rangle} = \frac{J(J+1)+S(S+1)-L(L+1)}{2J(J+1)}. \tag{10.151}$$

10.7.4.2 Landé factor g_J

In search for g_J we return to Eqs. (10.144) and (10.146). With the aid of the Wigner-Eckart theorem (10.147) as well as the relation (10.148) we obtain the expression

$$\begin{aligned} g_J &= g_L\langle LSJ\, \|L\|\, LSJ\rangle + g_e\langle LSJ\, \|S\|\, LSJ\rangle \\ &= \tfrac{1}{2}\,(g_L+g_e) + \tfrac{1}{2}\,(g_L-g_e)\,[\langle LSJ\, \|L\|\, LSJ\rangle - \langle LSJ\, \|S\|\, LSJ\rangle]\,. \end{aligned} \tag{10.152}$$

Substituting the expressions for the reduced matrix elements (10.150) and (10.151) we obtain for the g_J factor,

$$g_J = \tfrac{1}{2}\,(g_L+g_e) + \tfrac{1}{2}\,(g_L-g_e)\,\frac{L(L+1)-S(S+1)}{J(J+1)}. \tag{10.153}$$

In the important case of S terms $g_J = g_e$ as is intuitively clear for the absence of an orbital moment. Approximating $g_L = 1$ and $g_e = 2$ we find that g_J takes the form of the *Landé factor*

$$g_J = 1 + \frac{[J(J+1)+S(S+1)-L(L+1)]}{2J(J+1)}. \tag{10.154}$$

Note that just like the expressions for the high-field limit also the expressions for the low-field limit are valid for *arbitrary* values of L and S.

10.7.5 Low-field limit - quadratic Zeeman shift

For arbitrary value of S the quadratic shift can be calculated with the aid of second-order perturbation theory,

$$\Delta E^{(2)Z}_{J,M}\left(n\,^{2s+1}L_J\right) = \sum_{J'} \frac{|\langle LSJ'M|g_L\mu_B L_z + g_S\mu_B S_z|LSJM\rangle B/\hbar|^2}{E_{J,M}-E_{J',M}}. \tag{10.155}$$

Note that this contribution indeed scales like B^2. As L_z and S_z conserve M, the Zeeman operator couples states of different $J \in \{|J-S|,\cdots,J+S\}$ for given value of M.

We demonstrate the procedure for the special case in which *two* fine-structure levels, J' and $J = J'-1$, are coupled by the spin-orbit interaction. At sufficiently low fields, the energy splitting may be approximated by its zero-field value; i.e., by the interval rule (4.128), $\Delta W_J = \zeta_{nLS}J'$. The energy splitting also has a field dependence but if $g_J = g_{J'}$ the associated shift contributes in third or higher order. In any case, this field dependence is not included here. The quadratic shifts of the upper, J', and lower, $J = J'-1$, fine-structure levels (of given M) only differ in the sign, with the quadratic shifts of the upper manifold positive and those of the lower manifold negative. For the upper/lower manifold the quadratic shift becomes

$$\Delta E^{(2)Z}_{J'/J,M}\left(n\,^{2s+1}L_{J'/J}\right) = \pm\frac{|\langle LSJ'M|g_L L_z + g_S S_z|LSJM\rangle \mu_B B/\hbar|^2}{\zeta_{nLS}J'}. \tag{10.156}$$

Adding and subtracting $g_L\mu_B S_z$ and using the orthogonality relation $\langle LSJ'M|LSJM\rangle = 0$ as well as the definitions (4.174a) and (4.180) the Eq. (10.156) can be reduced to

$$\Delta E^{(2)Z}_{J'/J,M}\left(n\,^{2s+1}L_j\right) = \pm\zeta_{nLS}J'\,(B/B_{\text{fs}})^2\,|\langle LSJ'M|S_z/\hbar|LSJM\rangle|^2, \tag{10.157}$$

where

$$B_{\text{fs}} \equiv \zeta_{nLS}J'/\mu'_B, \tag{10.158}$$

with $\mu'_B \equiv (g_S - g_L)\mu_B$, is the fine-structure crossover field. Evaluating the matrix element we find (see Problem 10.4)

$$\Delta E^{(2)Z}_{J'/J,M}\left(n\,^{2s+1}L_j\right) = \pm\tfrac{1}{4}\zeta_{nLS}J'\,(B/B_{\text{fs}})^2\left(1-\widetilde{M}^2\right)R(LSJ') \tag{10.159}$$

where $\widetilde{M} = M/J'$ and

$$R(LSJ') \equiv \frac{(L+S+1+J')(J'-L+S)(J'+L-S)(L+S+1-J')}{(2J'-1)(2J'+1)}. \tag{10.160}$$

For $L=1$ and $s=\frac{1}{2}$ with $J'=L+S=\frac{3}{2}$ and $J=L-S=\frac{1}{2}$ we calculate $R(LSJ')=1$ and we regain the result from Eq. (4.184). Note that we indeed regained the quadratic term of Eq. (5.102). Since $\widetilde{M}^2 \le 1$ we note that the quadratic Zeeman shift is *largest* for the state of *smallest* $|M|$.

Problem 10.4. Derive the expression for the matrix element

$$\langle LSJ'M|S_z/\hbar|LSJM\rangle = \sqrt{\left(1-\widetilde{M}^2\right)\frac{(L+S+1+J')(J'-L+S)(J'+L-S)(L+S+1-J')}{4(2J'-1)(2J'+1)}}.$$

Solution. The matrix element is evaluated for arbitrary J' and $J = J'-1$ using the Wigner-Eckart theorem - see Eq. (K.24),

$$\langle LSJ'M|S_z/\hbar|LSJM\rangle = (-1)^{J'-M}\langle LSJ'||S||LSJ\rangle\begin{pmatrix} J' & 1 & J\\ -M & 0 & M\end{pmatrix},$$

where, in analogy with Eq. (K.62),

$$\langle LSJ'||S||LSJ\rangle = (-1)^{J+L+S}\langle S||S||S\rangle\sqrt{(2J+1)\,(2J'+1)}\begin{Bmatrix} S & J' & L\\ J & S & 1\end{Bmatrix},$$

with $\langle S||S||S\rangle = \sqrt{S(S+1)(2S+1)}$ - see Eq. (K.50). Combining these expressions we find

$$\langle LSJ'M|S_z/\hbar|LSJM\rangle = $$
$$(-1)^{J+J'+L+S-M}\sqrt{S(S+1)(2S+1)\,(2J+1)\,(2J'+1)}\begin{pmatrix} J' & 1 & J\\ -M & 0 & M\end{pmatrix}\begin{Bmatrix} S & J' & L\\ J & S & 1\end{Bmatrix}.$$

Since $J' = J+1$ we can use the special case (J.13) to evaluate the $3j$-symbol,

$$\begin{pmatrix} J' & 1 & J'-1\\ -M & 0 & M\end{pmatrix} = (-1)^{-J'+M}\sqrt{\frac{(J'+M)\,(J'-M)}{J'(2J'+1)(2J'-1)}},$$

and special case (J.33b) to evaluate the $6j$-symbol,

$$\begin{Bmatrix} S & J' & L\\ J'-1 & S & 1\end{Bmatrix} = (-1)^{J+L+S}\sqrt{\frac{2(L+S+1+J')(J'-L+S)(J'+L-S)(L+S+1-J')}{2S(2S-1)(2S+1)(2J'-1)2J'(2J'+1)}}.$$

Substituting the Wigner symbols we obtain the desired expression. □

10.8 jj coupling

10.8.1 Introduction

To discuss the limit of jj coupling we start from electron configurations of $\boldsymbol{l}\cdot\boldsymbol{s}$ coupled spinorbitals

$$|\beta_1\rangle = |nlsjm_j\rangle, \tag{10.161}$$

which can be combined into Slater determinants of the type

$$|\psi_\beta\rangle = |\beta_1, \cdots \beta_N\rangle \tag{10.162}$$

in order to satisfy Fermi-Dirac statistics. On the other hand we can use the angular momentum addition rules to determine all possible values of the total angular momentum

$$\mathbf{J} = \sum_i \boldsymbol{j}_i$$

In the case of jj-coupled configurations it is our task to determine for a given electron configuration which jj-coupled states are consistent with Fermi-Dirac statistics; i.e., can be expressed as a linear combination of (nonzero) Slater determinants. Once we know the relevant jj-coupled states we can calculate their spin-orbit splitting.

10.8.2 Partially filled shells with np^2 configuration

As the first example of jj-coupled states we return to the np^2 configuration; i.e., we return to the Hilbert space of dimension $(2l+1)^2(2s+1)^2 = 36$ for pairs of electrons. In the present context the pair states have to be expressed in terms of the basis of the ls-coupled representation $\{|nlsj_1m_{j_1}\rangle \otimes |nlsj_2m_{j_2}\rangle\}$ with $j_1, j_2 \in \{\frac{1}{2}, \frac{3}{2}\}$ since $l = 1$ and $s = \frac{1}{2}$. Using a unitary transformation this basis can be reexpressed in terms of a basis of 15 fully antisymmetric and 21 partly or fully symmetric *linearly independent* states. The 15 *linearly independent* antisymmetric states are readily identified by applying the Pauli principle on Slater determinants of ls-coupled orbitals, $|\beta_1, \beta_2\rangle = |j_1m_{j_1}, j_2m_{j_2}\rangle$. In the upper part of Table 10.11 they are grouped by the values of j_1, j_2 and $M_J = m_{j_1} + m_{j_2}$.

In a potential field of central symmetry the total electronic angular momentum $\mathbf{J} = \boldsymbol{j}_1 + \boldsymbol{j}_2$ is a conserved quantity; i.e., J is a good quantum number. So, let us have a closer look at the *jj-coupled representation.* For the np^2 configuration the total orbital angular quantum number can take the values $J = 0(2\times), 1(4\times), 2(3\times), 3(1\times)$; i.e., together again 36 angular momentum states can be identified, which we denote by

$$(j_1, j_2)_J = (\tfrac{1}{2}, \tfrac{1}{2})_0, (\tfrac{1}{2}, \tfrac{1}{2})_1, (\tfrac{1}{2}, \tfrac{3}{2})_1, (\tfrac{1}{2}, \tfrac{3}{2})_2, (\tfrac{3}{2}, \tfrac{1}{2})_1, (\tfrac{3}{2}, \tfrac{1}{2})_2, (\tfrac{3}{2}, \tfrac{3}{2})_0, (\tfrac{3}{2}, \tfrac{3}{2})_1, (\tfrac{3}{2}, \tfrac{3}{2})_2, (\tfrac{3}{2}, \tfrac{3}{2})_3. \tag{10.163}$$

These 36 jj-coupled states replace the 36 LS-coupled states of the Russell-Saunders limit: ${}^1S_0$, ${}^3S_1$, ${}^1P_1$, ${}^3P_{0,1,2}$, ${}^1D_2$ and ${}^3D_{1,2,3}$; 15 of these states are consistent with the Pauli principle and can be identified with a decision table analogously as we did for the LS terms. The Pauli-consistent terms are given in the lower part of Table 10.11.

To calculate the energy of electronic pair states we rely on the many-body formalism of Chapter 9 by which we can calculate matrix elements between determinantal states. Thus we use the same approach as we did for the LS terms and search for the determinant within a given degenerate manifold that can be evaluated most conveniently. For instance, the jj manifold $np^2(\frac{3}{2}, \frac{3}{2})_2$ contains the sublevel $|j_1, j_2; JM_J\rangle = |\frac{3}{2}, \frac{3}{2}; 2, 2\rangle_{np^2}$ which can be represented by the *single* Slater determinant $|n_1l_1sj_1m_{j_1}; n_2l_2sj_2m_{j_2}\rangle = |\frac{3}{2}, \frac{3}{2}; \frac{3}{2}, \frac{1}{2}\rangle_{np^2}$. This can be done for several manifolds and these can be identified with the aid of Table 10.3,

$$np^2(\tfrac{3}{2}, \tfrac{3}{2})_2 \rightarrow |\tfrac{3}{2}, \tfrac{3}{2}; 2, 2\rangle_{np^2} = |\tfrac{3}{2}, \tfrac{3}{2}; \tfrac{3}{2}, \tfrac{1}{2}\rangle_{np^2} \tag{10.164}$$

$$np^2(\tfrac{3}{2}, \tfrac{1}{2})_2 \rightarrow |\tfrac{3}{2}, \tfrac{1}{2}; 2, 2\rangle_{np^2} = |\tfrac{3}{2}, \tfrac{3}{2}; \tfrac{1}{2}, \tfrac{1}{2}\rangle_{np^2} \tag{10.165}$$

$$np^2(\tfrac{3}{2}, \tfrac{1}{2})_0 \rightarrow |\tfrac{1}{2}, \tfrac{1}{2}; 0, 0\rangle_{np^2} = |\tfrac{1}{2}, \tfrac{1}{2}; \tfrac{1}{2}, -\tfrac{1}{2}\rangle_{np^2}. \tag{10.166}$$

Table 10.11: Example np^2 configuration: (top) uncoupled representation - the 15 linearly independent pair states consistent with the Pauli principle; (bottom) coupled representation - all jj-coupled angular momenta consistent with the Pauli principle (again 15 linearly independent states - including degeneracy).

np^2		j,j'			deg.
uncoupled		$\frac{3}{2},\frac{3}{2}$	$\frac{3}{2},\frac{1}{2}$	$\frac{1}{2},\frac{1}{2}$	15
		$\vert m_j,m_{j'}\rangle$			
M_J	2	$\vert\frac{3}{2},\frac{1}{2}\rangle$	$\vert\frac{3}{2},\frac{1}{2}\rangle$		2
	1	$\vert\frac{3}{2},-\frac{1}{2}\rangle$	$\vert\frac{3}{2},-\frac{1}{2}\rangle\vert\frac{1}{2},\frac{1}{2}\rangle$		3
	0	$\vert\frac{3}{2},-\frac{3}{2}\rangle\vert\frac{1}{2},-\frac{1}{2}\rangle$	$\vert\frac{1}{2},-\frac{1}{2}\rangle\vert-\frac{1}{2},\frac{1}{2}\rangle$	$\vert\frac{1}{2},-\frac{1}{2}\rangle$	5
	-1	$\vert-\frac{3}{2},\frac{1}{2}\rangle$	$\vert-\frac{3}{2},\frac{1}{2}\rangle\vert-\frac{1}{2},-\frac{1}{2}\rangle$		3
	-2	$\vert-\frac{3}{2},-\frac{1}{2}\rangle$	$\vert-\frac{3}{2},-\frac{1}{2}\rangle$		2

np^2					deg.
coupled		$(j,j')_J$			15
J	0	$(\frac{3}{2},\frac{3}{2})_0$		$(\frac{1}{2},\frac{1}{2})_0$	2
	1		$(\frac{3}{2},\frac{1}{2})_1$		3
	2	$(\frac{3}{2},\frac{3}{2})_2$	$(\frac{3}{2},\frac{1}{2})_2$		10

Once the energy of these manifolds is known the energy of the remaining manifolds, $np^2(\frac{3}{2},\frac{3}{2})_0$ and $np^2(\frac{3}{2},\frac{1}{2})_1$, can be determined using the Slater sum rule.

Let us apply this strategy to calculate the spin-orbit energy of the 5 Pauli-consistent jj manifolds

$$(j_1,j_2)_J=(\tfrac{1}{2},\tfrac{1}{2})_0,\ (\tfrac{3}{2},\tfrac{1}{2})_1,\ (\tfrac{3}{2},\tfrac{1}{2})_2,\ (\tfrac{3}{2},\tfrac{3}{2})_0 \text{ and } (\tfrac{3}{2},\tfrac{3}{2})_2$$

of the np^2 configuration. For this purpose we write the spin-orbit Hamiltonian in the form

$$\mathcal{H}_{LS}=\sum_i \xi_i(r)\boldsymbol{l}_i\cdot\boldsymbol{s}_i=\frac{1}{2}\sum_i \xi_i(r)[\boldsymbol{j}_i^2-\boldsymbol{l}_i^2-\boldsymbol{s}_i^2], \tag{10.167}$$

where we recognize a sum over one-body operators which are diagonal in the $\{|j_i m_{j_i}\rangle\}$ representation. For the determinantal state $|j_1m_{j_1},j_2m_{j_2}\rangle_{np^2}$ the spin-orbit shift is given by

$$\begin{aligned}\Delta E_{np^2}(j_1,j_2)_J&=\langle j_1m_{j_1},j_2m_{j_2}|\mathcal{H}_{LS}|j_1m_{j_1},j_2m_{j_2}\rangle_{np^2}\\&=\tfrac{1}{2}\sum_i\langle j_1m_{j_1},j_2m_{j_2}|\xi_i(r)[\boldsymbol{j}_i^2-\boldsymbol{l}_i^2-\boldsymbol{s}_i^2]|j_1m_{j_1},j_2m_{j_2}\rangle_{np^2}.\end{aligned} \tag{10.168}$$

Changing from summation over particle index to summation over state index, see Eq. (9.44), we obtain

$$\begin{aligned}\Delta E_{np^2}(j_1,j_2)_J&=\tfrac{1}{2}\zeta_{np}\sum_\kappa\langle j^\kappa m_j^\kappa|\boldsymbol{j}^2-\boldsymbol{l}^2-\boldsymbol{s}^2|j^\kappa m_j^\kappa\rangle_{np}\\&=\tfrac{1}{2}\zeta_{np}\sum_\kappa[j^\kappa(j^\kappa+1)-l(l+1)-s(s+1)],\end{aligned} \tag{10.169}$$

where $l=1$ and $s=\frac{1}{2}$. Note that this result is independent of the magnetic quantum numbers, which make the application of the Slater sum rule particularly simple in this case. After evaluation we obtain for the 5 Pauli-consistent jj terms

$$\left.\begin{aligned}\Delta E_{np^2}(\tfrac{3}{2},\tfrac{3}{2})_0\\ \Delta E_{np^2}(\tfrac{3}{2},\tfrac{3}{2})_2\end{aligned}\right\} = \zeta_{np} \tag{10.170}$$

$$\left.\begin{aligned}\Delta E_{np^2}(\tfrac{3}{2},\tfrac{1}{2})_2\\ \Delta E_{np^2}(\tfrac{3}{2},\tfrac{1}{2})_1\end{aligned}\right\} = -\tfrac{1}{2}\zeta_{np} \tag{10.171}$$

$$\Delta E_{np^2}(\tfrac{1}{2},\tfrac{1}{2})_0 = -2\zeta_{np}, \tag{10.172}$$

where the Slater sum rule was used to calculate $\Delta E_{np^2}(\frac{3}{2},\frac{3}{2})_0$ and $\Delta E_{np^2}(\frac{3}{2},\frac{1}{2})_1$.

10.8.3 Coulomb shift of the jj-coupled states

In this section we consider the Coulomb interaction between the electrons as a perturbation of the jj-coupled manifolds. The calculation proceeds in a few steps. We demonstrate this for the $np^2(\frac{3}{2},\frac{3}{2})_2$ term,

$$\begin{aligned}\Delta E\ \left[np^2(\tfrac{3}{2},\tfrac{3}{2})_2\right] &= \langle\tfrac{3}{2}\tfrac{3}{2},\tfrac{3}{2}\tfrac{1}{2}|\rho_{12}^{-1}|\tfrac{3}{2}\tfrac{3}{2},\tfrac{3}{2}\tfrac{1}{2}\rangle_{np^2}\\ &= (\tfrac{3}{2}\tfrac{3}{2},\tfrac{3}{2}\tfrac{1}{2}|\rho_{12}^{-1}|\tfrac{3}{2}\tfrac{3}{2},\tfrac{3}{2}\tfrac{1}{2})_{np^2} - (\tfrac{3}{2}\tfrac{3}{2},\tfrac{3}{2}\tfrac{1}{2}|\rho_{12}^{-1}|\tfrac{3}{2}\tfrac{1}{2},\tfrac{3}{2}\tfrac{3}{2})_{np^2}.\end{aligned} \tag{10.173}$$

To evaluate the Coulomb integrals we have to turn from the $\{|nlsjm_j\rangle\}$ to the $\{|nlm_lsm_s\rangle\}$ representation using the Clebsch-Gordan decomposition

$$|j_1m_{j_1}\rangle = \sum_{m_l,m_s}|lm_lsm_s\rangle\langle lm_lsm_s|j_1m_{j_1}\rangle. \tag{10.174}$$

We demonstrate this for $|j_1m_{j_1}\rangle = |\frac{3}{2},\frac{3}{2}\rangle_{np}$ and $|j_1m_{j_1}\rangle = |\frac{3}{2},\frac{1}{2}\rangle_{np}$; using the Clebsch-Gordan Table J.2.1 ($1\times 1/2$) we obtain

$$|\tfrac{3}{2},\tfrac{3}{2}\rangle_{np} = |p_1\rangle \tag{10.175}$$

$$|\tfrac{3}{2},\tfrac{1}{2}\rangle_{np} = \sqrt{2/3}|p_0\rangle + \sqrt{1/3}|\bar{p}_1\rangle. \tag{10.176}$$

The corresponding unsymmetrized pair states are

$$|\tfrac{3}{2},\tfrac{1}{2};\tfrac{3}{2},\tfrac{3}{2})_{np^2} = \sqrt{2/3}|p_0,p_1) + \sqrt{1/3}|\bar{p}_1,p_1) \tag{10.177}$$

$$|\tfrac{3}{2},\tfrac{3}{2};\tfrac{3}{2},\tfrac{1}{2})_{np^2} = \sqrt{2/3}|p_1,p_0) + \sqrt{1/3}|p_1,\bar{p}_1). \tag{10.178}$$

Using these expressions the Coulomb shift $\Delta E_{np}(\frac{3}{2},\frac{3}{2})_2$ is expressed in the form

$$\begin{aligned}\Delta E(\tfrac{3}{2},\tfrac{3}{2})_2^{np^2} &= 2/3(p_1,p_0|\rho_{12}^{-1}|p_1,p_0) - 2/3(p_1,p_0|\rho_{12}^{-1}|p_0,p_1)\\ &\quad + 1/3(p_1,\bar{p}_1|\rho_{12}^{-1}|p_1,\bar{p}_1) - 1/3(p_1,\bar{p}_1|\rho_{12}^{-1}|\bar{p}_1,p_1)\\ &\quad + \sqrt{2}/3(p_1,p_0|\rho_{12}^{-1}|p_1,\bar{p}_1) - \sqrt{2}/3(p_1,p_0|\rho_{12}^{-1}|\bar{p}_1,p_1)\\ &\quad + \sqrt{2}/3(p_1,\bar{p}_1|\rho_{12}^{-1}|p_1,p_0) - \sqrt{2}/3(p_1,\bar{p}_1|\rho_{12}^{-1}|p_0,p_1).\end{aligned} \tag{10.179}$$

Note that only the first three terms give a nonzero contribution; the others vanish by spin orthogonality. With the aid of Table 7.1 these evaluate to,

$$\begin{aligned}\Delta E(\tfrac{3}{2},\tfrac{3}{2})_2^{np^2} &= 2/3\mathcal{J}(p_1,p_0) - 2/3\mathcal{K}(p_1,p_0) + 1/3\mathcal{J}(p_1,p_1)\\ &= 2/3\,(F_0-2F_2) - 2/3\,(3G_2) + 1/3\,(F_0+F_2) = F_0 - 3F_2.\end{aligned} \tag{10.180}$$

A

Periodic table of the elements

Table A.1: Eight primary groups cover the filling of s and p shells. The secondary groups 3-13 are the transition metals and correspond to the filling of d shells. The rare-earth elements (lanthanides and actinides) correspond to filling of the f shells.

C

Properties of the elements

Table C.1: Configuration, Ground term, Ionization Energy (IE) and Electron Affinity (EA) of the first three rows of the periodic table. Note that all half-filled and fully-filled shells have an S term ground state and that the electron affinity of fully-filled shells vanishes. The table is based on the NIST Atomic Spectra Database [66]. The Electron Affinities (EA) are from T. Andersen, H.K. Haugen, H. Hotop [3].

				ground term	IE in eV						EA in eV
Z	Element		configuration		1s	2s	2p	3s	3p	3d	
1	Hydrogen	H	1s	$^2S_{1/2}$	13.60						0.75
2	Helium	He	1s^2	$^1S_0$	24.59						< 0
3	Lithium	Li	[He]2s	$^2S_{1/2}$		5.39					0.62
4	Beryllium	Be	[He]2s^2	$^1S_0$		9.32					< 0
5	Boron	B	[He]2s^{2}2p	$^2P_{1/2}$			8.30				0.28
6	Carbon	C	[He]2s^{2}2p^2	$^3P_0$			11.26				1.26
7	Nitrogen	N	[He]2s^{2}2p^3	$^4S_{3/2}$			14.53				-0.07
8	Oxygen	O	[He]2s^{2}2p^4	$^3P_2$			13.62				1.46
9	Fluorine	F	[He]2s^{2}2p^5	$^2P_{3/2}$			17.42				3.40
10	Ne	Ne	[He]2s^{2}2p^6	$^1S_0$			21.56				< 0
11	Sodium	Na	[Ne]3s	$^2S_{1/2}$				5.14			0.55
12	Magnesium	Mg	[Ne]3s^2	$^1S_0$				7.65			< 0
13	Aluminium	Al	[Ne]3s^{2}3p	$^2P_{1/2}$					5.99		0.43
14	Silicon	Si	[Ne]3s^{2}3p^2	$^3P_0$					8.15		1.39
15	Phosphorus	P	[Ne]3s^{2}3p^3	$^4S_{3/2}$					10.49		0.75
16	Sulphur	S	[Ne]3s^{2}3p^4	$^3P_2$					10.36		2.08
17	Chlorine	Cl	[Ne]3s^{2}3p^5	$^2P_{3/2}$					12.97		3.61
18	Argon	Ar	[Ne]3s^{2}3p^6	$^1S_0$					15.76		< 0

Table C.2: Configuration, Ground term, Ionization energy (IE) and Electron affinity (EA) of the fourth and fifth row of the periodic table. This includes the filling of the 3d and 4d shells (transition metals). The table is based on the NIST Atomic Spectra Database [66]. The Electron Affinities (EA) are from T. Andersen, H.K. Haugen, H. Hotop [3].

				ground	IE in eV						EA in eV
Z	Element		configuration	term	3d	4s	4p	4d	5s	5p

D

Classical Mechanics

D.1 Introduction

The goal of *classical mechanics* is to describe the time evolution of systems of point-like particles, called *classical particles*, subject to Newton's laws of motion. To introduce the subject we consider a mechanical *system* of N classical particles labeled by the *particle index* α. The *position* of particle α is denoted by the vector $\mathbf{r}_\alpha$. The first derivative with respect to time t, $\dot{\mathbf{r}}_\alpha \equiv d\mathbf{r}_\alpha/dt$, is called the *velocity* of the particle and the second derivative, $\ddot{\mathbf{r}}_\alpha \equiv d^2\mathbf{r}_\alpha/dt^2$, its *acceleration.*

We suppose that for a given state of the system the evolution does not depend on the instant that we choose to follow it in time; i.e., *time is homogeneous*. Space is taken to be both *homogeneous and isotropic*; i.e., it is possible to choose a frame of reference in which the evolution of the system is independent of position and orientation. Such a reference frame is called an *inertial* frame. In an inertial frame a *free* particle either stays at rest or moves at constant velocity. This is *Newton's first law*: the law of inertia.

A system of N classical particles has at most $3N$ *degrees of freedom*; i.e., $3N$ independent ways to change in time. For *free* particles this motion can be described by Newton's equations of motion using $3N$ coordinates, for instance the cartesian coordinates x_α, y_α and z_α, with $\alpha \in \{1, \cdots N\}$. However, in many cases the motion is not free (not described by) but subject to constraints. These can be time independent (*scleronomous*) or have an explicit time dependence (*rheonomous*). An example of a scleronomous constraint is the fixed distance between two particles in a rotating rigid body. A ball rolling on the deck of a ship is an example of a system (the ball) with a rheonomous constraint (confinement to the deck of the ship). The system is called *holonomic* if the constraining relations reduce the $3N$ degrees of freedom the system (which can greatly simplify calculations). This is the case for constraint *equalities*, for instance the above mentioned fixed distance between two particles in a rotating rigid body. If the constraints do *not* affect the $3N$ degrees of freedom the system is called *nonholonomic.* An example is a system of particles confined to a box, where the confinement is accounted for by constraint *inequalities.* Nonholonomic constraints can sometimes be avoided by idealizations of the theory.

The field of classical mechanics is subdivided into three subjects: (a) *statics*, which is the theory of mechanical equilibrium between forces; (b) *kinematics*, which is the theory of motion without entering in the origin of this motion; (c) *dynamics*, which is the theory of motion under the influence of forces. This appendix cannot be more than a summary. It is partially based on unplublished lecture notes by De Groot and Suttorp at the University of Amsterdam. For a comprehensive introduction the reader is referred to volume 1 of the Landau-Lifshitz series [69] and the book by Herbert Goldstein [52].

D.2 Dynamical evolution

D.2.1 Newton's equation of motion

The time development of a system of N particles under the influence of external forces is called the *dynamical evolution* of that system. In classical mechanics the dynamical evolution of a single particle is described by *Newton's second law*, which states that the total force $\mathbf{F}_\alpha$ acting on particle α is proportional to the acceleration of that particle, with the proportionality constant m_α being its *inertial mass*,

$$\mathbf{F}_\alpha = m_\alpha \ddot{\mathbf{r}}_\alpha. \tag{D.1}$$

For a system of N particles the force $\mathbf{F}_\alpha$ is given by the resultant of all external forces, $\mathbf{F}_\alpha^{\mathrm{ext}}$, and the sum of the interaction forces $\mathbf{F}_{\alpha\beta}$ of particle α with all other particles of the system,

$$\mathbf{F}_\alpha^{\mathrm{ext}} + {\sum_{\beta=1}^{N}}{}' \mathbf{F}_{\alpha\beta} = m_\alpha \ddot{\mathbf{r}}_\alpha, \tag{D.2}$$

where the prime indicates the condition $\beta \neq \alpha$. This expression represents a set of N coupled differential equations which is impossible to solve for a macroscopic number of particles. However, as we shall see below, in many cases excellent approximations can be obtained by replacing the interparticle forces by one or more relations acting as constraints on the motion of particle α.

D.2.2 Kinematic evolution of holonomous systems

For a *holonomic* system of N particles at positions $\mathbf{r}_\alpha$ with l constraints we can introduce $f = 3N - l$ *independent* coordinates $q_i(t)$ known as the *generalized coordinates*, with $i \in \{1, \cdots f\}$ being the *coordinate index.* Together these define the evolution of the system as a function of time in the f-dimensional *configuration space* of the system. The time derivatives $\dot{q}_i(t)$ are called the *generalized velocities.*[1]

- The *rheonomous* constraints of a N-particle system with $f = 3N - l$ degrees of freedom constitute a set of l *time-dependent* relations $f_k(\mathbf{r}_1, \cdots, \mathbf{r}_N, t) = 0$, where $k \in \{1, \cdots l\}$ is called the *constraint index.* In this case the position of particle α may be expressed as a function of the f coordinates q_i plus time,

  $$\mathbf{r}_\alpha = \mathbf{r}_\alpha(q_1, \cdots, q_f, t). \tag{D.3}$$

  The velocities follow with

  $$\dot{\mathbf{r}}_\alpha = \sum_{i=1}^{f} \frac{\partial \mathbf{r}_\alpha}{\partial q_i} \dot{q}_i + \frac{\partial \mathbf{r}_\alpha}{\partial t}, \tag{D.4}$$

  which shows that the velocity of particle α is (in general) a function of $q_i, \dot{q}_i$ and t,

  $$\dot{\mathbf{r}}_\alpha = \dot{\mathbf{r}}_\alpha(q_1, \cdots, q_f, \dot{q}_1, \cdots, \dot{q}_f, t). \tag{D.5}$$

  Hence, in *rheonomous* systems $\mathbf{r}_\alpha$ and $\dot{\mathbf{r}}_\alpha$ depend *explicitly* on time.

- For *scleronomous* constraints the l constraining relations do *not* contain an explicit time dependence: $f_k(\mathbf{r}_1, \cdots, \mathbf{r}_N) = 0$, with $k \in \{1, \cdots l\}$. This makes it possible to *choose* the f coordinates q_i in such a way that the position of the particles does not depend explicitly on time. For instance, a rigid body has $f = 6$ degrees of freedom, because the position of an arbitrary particle α is specified by $\mathbf{r}_\alpha = \mathbf{r}_\alpha(X, Y, Z, r, \theta, \phi)$, where $\mathbf{R} = (X, Y, Z)$ is the position of the center of mass and $\mathbf{r} = (r, \theta, \phi)$ to position relative to $\mathbf{R}$ inside the body. For a homogeneous rigid sphere on a static surface this reduces to $f = 4$ and $\mathbf{r}_\alpha = \mathbf{r}_\alpha(X, Y, \theta, \phi)$.

---

[1] In this appendix we adopt the following index convention: $\alpha \in \{1, \cdots N\}$ for the *particle index*, $i \in \{1, \cdots f\}$ for the *coordinate index* and $k \in \{1, \cdots l\}$. for the *constraint index.*

D.2.3 Virtual displacements - principle of d'Alembert

The force $\mathbf{F}_\alpha$ acting on particle α is the superposition of all forces acting on that particle. These forces can be separated into *known* forces $\mathbf{F}_\alpha^{\mathrm{ext}}$, like gravity or externally applied forces, and *unknown* forces $\mathbf{K}_\alpha$,

$$\mathbf{F}_\alpha = \mathbf{F}_\alpha^{\mathrm{ext}} + \mathbf{K}_\alpha. \tag{D.6}$$

The unknown forces are called *forces of constraint.* These unknown forces are *reaction forces* that reduce the freedom of motion of the particles. Their actual value is unknown but always such that the constraints remain satisfied, for instance to assure that a train stays in the rails.

The explicit appearance of the reaction forces can be eliminated from the formalism. To demonstrate this we first consider *mechanical equilibrium.* This is the state in which all particles are at rest in their equilibrium position; i.e., $\mathbf{F}_\alpha = 0$ and $\mathbf{K}_\alpha = -\mathbf{F}_\alpha^{\mathrm{ext}}$ for all particles. By pulling on one of the particles we expect to perform work against the restoring force of the system but as long as the displacements $\delta\mathbf{r}_\alpha$ remain small (i.e., close to the equilibrium position) we find that this work vanishes because the forces $\mathbf{F}_\alpha$ remain vanishingly small,

$$\sum_\alpha \mathbf{F}_\alpha \cdot \delta\mathbf{r}_\alpha = \sum_\alpha (\mathbf{F}_\alpha^{\mathrm{ext}} + \mathbf{K}_\alpha) \cdot \delta\mathbf{r}_\alpha = 0. \tag{D.7}$$

In other words, in equilibrium the restoring force is zero. This implies that in the absence of external forces the reaction forces have to be zero, $\mathbf{F}_\alpha = \mathbf{K}_\alpha = 0$.

Now suppose that the system is pulled *out of equilibrium.* In this case we have forces acting on (in general) all the particles; i.e., $\mathbf{F}_\alpha = m_\alpha \ddot{\mathbf{r}}_\alpha \neq 0$ and $\mathbf{K}_\alpha = -\mathbf{F}_\alpha^{\mathrm{ext}} + \mathbf{F}_\alpha \neq 0$. Shifting the external forces to the l.h.s. of (D.7) this equation takes the form

$$\sum_\alpha (m_\alpha \ddot{\mathbf{r}}_\alpha - \mathbf{F}_\alpha^{\mathrm{ext}}) \cdot \delta\mathbf{r}_\alpha = \sum_\alpha \mathbf{K}_\alpha \cdot \delta\mathbf{r}_\alpha. \tag{D.8}$$

The dot product leads us to distinguish between the component of $\delta\mathbf{r}_\alpha$ along $\mathbf{K}_\alpha$ and the component perpendicular to $\mathbf{K}_\alpha$. A parallel displacement would require work but is not in accordance with the constraints; a perpendicular displacement is in accordance with the constraints but does not result in work (as long as the displacements remain sufficiently small). This insight brings us to the *principle of d'Alembert*: under *virtual displacements* $\delta\mathbf{r}_\alpha$ (in accordance with the constraints) no work is done by the reaction forces,

$$\delta W = \sum_\alpha \mathbf{K}_\alpha \cdot \delta\mathbf{r}_\alpha = 0. \tag{D.9}$$

By analyzing virtual displacement we can eliminate the reaction forces from (D.8) and the principle of d'Alembert takes the form

$$\delta W = \sum_\alpha (m_\alpha \ddot{\mathbf{r}}_\alpha - \mathbf{F}_\alpha^{\mathrm{ext}}) \cdot \delta\mathbf{r}_\alpha = 0. \tag{D.10}$$

As this expression also holds outside equilibrium, we have obtained a condition for the *dynamical* evolution of a mechanical system in which the constraints are satisfied implicitly. In Section D.3 the d'Alembert principle will be used to derive the central equations of classical mechanics: the equations of Lagrange.

Let us have a closer look at the virtual displacements. These can be thought of as instantly being present at any desired point in time just to analyze how they would affect the system; i.e., unlike real displacements, which are based on (D.3), virtual displacements have *no* (explicit) time dependence. To be relevant, they have to be in accordance with the constraints; i.e., $\delta\mathbf{r}_\alpha$ has to be perpendicular to $\mathbf{K}_\alpha$. This leads to the practical difficulty that (in principle) the virtual displacement of one particle affects the virtual reaction forces of all other particles; i.e., the $\delta\mathbf{r}_\alpha$ cannot be chosen independently. This difficulty can be eliminated by decomposing the virtual displacements in terms of the generalized coordinates defined by the constraints,

$$\delta\mathbf{r}_\alpha = \sum_{i=1}^{f} \frac{\partial\mathbf{r}_\alpha}{\partial q_i}\delta q_i. \tag{D.11}$$

Note the absence of the time variable. Substituting this expression into (D.10) we obtain

$$\delta W = \sum_{i=1}^{f}\left[\sum_{\alpha=1}^{N}(m_\alpha\ddot{\mathbf{r}}_\alpha - \mathbf{F}_\alpha^{\text{ext}})\cdot\frac{\partial\mathbf{r}_\alpha}{\partial q_i}\right]\delta q_i = 0 \tag{D.12}$$

and since the q_i are independent variables the principle of d'Alembert takes the form of a set of f coupled differential equations

$$\sum_\alpha(m_\alpha\ddot{\mathbf{r}}_\alpha - \mathbf{F}_\alpha^{\text{ext}})\cdot\frac{\partial\mathbf{r}_\alpha}{\partial q_i} = 0, \quad \text{with } i\in\{1,\cdots,f\}. \tag{D.13}$$

Inversely, it is easily verified that (D.10) is always valid provided the equations (D.13) are simultaneously satisfied.

Bernoulli's principle

In the absence of dynamical evolution (the *static* case - $\ddot{\mathbf{r}}_\alpha = 0$) the principle of d'Alembert reduces to the *Bernoulli principle* of virtual displacements :

$$\delta W = \sum_\alpha \mathbf{F}_\alpha^{\text{ext}}\cdot\delta\mathbf{r}_\alpha = 0. \tag{D.14}$$

As an example of *Bernoulli's principle* without constraints we consider a system of $N = 2$ identical particles subject to a force $\mathbf{F}_\alpha^{\text{ext}} = -\boldsymbol{\nabla}_\alpha U(\mathbf{r}_1,\mathbf{r}_2)$, where $U(\mathbf{r}_1,\mathbf{r}_2)$ is a potential function which depends on the position of both particles. This is an example of a conservative force (see Section D.5.2). The expression for the virtual work is $\delta W = \mathbf{F}_1^{\text{ext}}\cdot\delta\mathbf{r}_1 + \mathbf{F}_2^{\text{ext}}\cdot\delta\mathbf{r}_2 = 0$. For two free particles confined by a harmonic potential the condition $\delta W = 0$ is satisfied at the minimum of the potential. For two repulsive particles we have $\mathbf{F}_1^{\text{ext}} = -\mathbf{F}_2^{\text{ext}}$ and the condition $\delta W = 0$ is satisfied for $\delta\mathbf{r}_1 = -\delta\mathbf{r}_2$ perpendicular to $\mathbf{F}_1^{\text{ext}}$. Note the correlation between $\delta\mathbf{r}_1$ and $\delta\mathbf{r}_2$ (these are *not* independent). The virtual displacements correspond to a rotation of the pair about the potential center. The latter case shows that the virtual variation does not automatically correspond to minimum of δW but can also represent a degenerate case.

Kinetic energy relations

Introducing the *kinetic energy*,

$$T \equiv \tfrac{1}{2}\sum_\alpha m_\alpha\dot{\mathbf{r}}_\alpha^2, \tag{D.15}$$

we note that, in view of (D.5), the kinetic energy of particle α is in the most general case a function of $q_i(t), \dot{q}_i(t)$ and t,

$$T = T(q_1,\cdots,q_f,\dot{q}_1,\cdots,\dot{q}_f,t). \tag{D.16}$$

For future convenience of use we derive the partial derivatives with respect to q_i and $\dot{q}_i$,

$$\frac{\partial T}{\partial q_i} = \sum_\alpha m_\alpha\dot{\mathbf{r}}_\alpha\cdot\frac{\partial\dot{\mathbf{r}}_\alpha}{\partial q_i} \tag{D.17a}$$

$$\frac{\partial T}{\partial \dot{q}_i} = \sum_\alpha m_\alpha\dot{\mathbf{r}}_\alpha\cdot\frac{\partial\mathbf{r}_\alpha}{\partial q_i}. \tag{D.17b}$$

Here we used the relation $\partial\dot{\mathbf{r}}_\alpha/\partial\dot{q}_i = \partial\mathbf{r}_\alpha/\partial q_i$, which follows immediately from (D.4) and (D.3).

Problem D.1. Consider the kinematics of a single particle moving in a stationary circular orbit of radius $R = 1$. Derive the equations of motion and show that motion is in accordance with the principle of d'Alembert.

Solution. To describe the orbit we choose a two-dimensional cartesian coordinate system with the position vector $\mathbf{r}$ given by

$$x = r\cos\phi \qquad y = r\sin\phi,$$

where (x, y) are the cartesian coordinates and (r, ϕ) the polar coordinates of $\mathbf{r}$. In this problem we have one (skeronomic) constraint: the radius of the orbit is constant. Choosing the origin of the coordinate system at the center of the circle the constraint takes the form $r = 1$ and the motion can be described using ϕ as the only generalized coordinate, $\mathbf{r} = \mathbf{r}(\phi)$. The time evolution is given by

$$\begin{aligned} x(t) &= \cos\omega t, \quad & \dot{x}(t) &= -\omega\sin\omega t, \quad & \ddot{x}(t) &= -\omega^2\cos\omega t \\ y(t) &= \sin\omega t, \quad & \dot{y}(t) &= \omega\cos\omega t, \quad & \ddot{y}(t) &= -\omega^2\sin\omega t, \end{aligned}$$

where $\phi(t) \equiv \omega t$, with $\omega = \dot{\phi}$ the angular velocity about the origin. These expressions show that the velocity is always tangential to the circle with the acceleration pointing to the center. Note that the velocity is proportional to ω and the acceleration scales with ω^2. As there are no "known" forces acting on the particle, the d'Alembert principle tells us that the force must a reaction force, $\mathbf{K} = m\ddot{\mathbf{r}}$, which constrains the orbit of the particle to the circle. Furthermore, as no work is done by reaction forces under virtual displacements,

$$\delta W = m\ddot{\mathbf{r}} \cdot \delta\mathbf{r} = 0,$$

the virtual displacements have to be orthogonal to the force; i.e., tangential to the circle (in accordance with the constraint $r = 1$). Note that the x and y motion only differ by a constant phase shift. Hence, the circular motion maps on that of a one-dimentional harmonic oscillator, which also is a mechanical system with one degree of freedom ($f = 1$). □

D.3 Lagrange equations

In this section we derive the equations of Lagrange, which are the equations of motion of classical mechanics. The Lagrange equations offer important advantages over Newton's equations of motion because forces of constraint are eliminated from the formalism. In this way the *state* of a classical system of f degrees of freedom can be uniquely specified by a set of $2f$ generalized coordinates,

$$(\mathbf{q}, \dot{\mathbf{q}}) \equiv (q_1, \cdots, q_f; \dot{q}_1, \cdots, \dot{q}_f). \tag{D.18}$$

This set is known as the *classical phase* of the system. As the generalized coordinates are linearly independent, the classical phase corresponds to a point in a $2f$-dimensional vector space, called the (generalized) *phase space* of the system. Each point in the phase space corresponds to a different *classical state*. In the Lagrange equations the vectors $\mathbf{q} \equiv (q_1, \cdots, q_f)$ and $\dot{\mathbf{q}} \equiv (\dot{q}_1, \cdots, \dot{q}_f)$ serve as *dynamical variables* because the evolution of the classical phase in time represents the dynamical evolution of the system. Separately, $\mathbf{q}$ and $\dot{\mathbf{q}}$ evolve as vectors in the (generalized) *configuration space* and (generalized) *velocity space*, respectively. The Lagrange equations are equally valid for conservative and non-conservative forces. Examples of conservative forces are the *gravitational* force and the *Lorentz* force. The friction force is an example of a non-conservative force. In the present section the Lagrange equations are obtained from the principle of d'Alembert. In Section D.4 they will be derived from the principle of least action of Hamilton.

D.3.1 Absence of constraining forces

First we show how the Lagrange equations are obtained form Newton's second law. In the absence of constraining forces the particles are called *free* and the equations of motion (D.1) suffice to describe the motion of the particles. Using Eq. (D.15) for the kinetic energy, we find that a force acting on particle α can be written in the form

$$\mathbf{F}_\alpha = \frac{d}{dt}\frac{\partial T}{\partial \dot{\mathbf{r}}_\alpha}. \tag{D.19}$$

Now we restrict ourselves to forces that can be expressed as the negative gradient of a *potential function* $U = U(\mathbf{r}_1, \cdots, \mathbf{r}_N, t)$,

$$\mathbf{F}_\alpha^{\text{ext}} = -\frac{\partial U}{\partial \mathbf{r}_\alpha}. \tag{D.20}$$

In the special case of a *time-independent* potential function the force field is called *conservative* and potential function can be interpreted as the *potential energy* $U = V(\mathbf{r}_1, \cdots, \mathbf{r}_N)$. We return to the concept of potential energy in the context of the conservation laws (see Section D.5.2). Combining (D.19) and (D.20) we find

$$-\frac{\partial U}{\partial \mathbf{r}_\alpha} = \frac{d}{dt}\frac{\partial T}{\partial \dot{\mathbf{r}}_\alpha}. \tag{D.21}$$

At this point we introduce the *Lagrangian* $\mathcal{L}(\mathbf{r}_\alpha, \dot{\mathbf{r}}_\alpha, t)$ as the difference between the kinetic energy and the potential function,

$$\mathcal{L}(\mathbf{r}_\alpha, \dot{\mathbf{r}}_\alpha, t) \equiv T(\dot{\mathbf{r}}_\alpha) - U(\mathbf{r}_\alpha, t). \tag{D.22}$$

Because the potential function $U(\mathbf{r}_1, \cdots, \mathbf{r}_N, t)$ does not depend explicitly on $\dot{\mathbf{r}}_\alpha$, and $T(\dot{\mathbf{r}}_1, \cdots, \dot{\mathbf{r}}_N)$ not explicitly on $\mathbf{r}_\alpha$, (D.21) we arrive at the so-called *Lagrange equations* for particle α,

$$\frac{d}{dt}\frac{\partial \mathcal{L}}{\partial \dot{\mathbf{r}}_\alpha} - \frac{\partial \mathcal{L}}{\partial \mathbf{r}_\alpha} = 0, \quad \text{with } \alpha \in \{1, \cdots, N\}. \tag{D.23}$$

D.3.2 Presence of constraining forces

Lagrange equations can also be derived for systems with *holonomic* constraints. So let us turn to a system of N particles in which *holonomic* constraints add up to the reaction forces $\mathbf{K}_\alpha$. How do these constraints affect the evolution of the system? To answer this question we apply the principle of d'Alembert. Rewriting (D.13) in the form

$$\sum_\alpha \mathbf{F}_\alpha^{\text{ext}} \cdot \frac{\partial \mathbf{r}_\alpha}{\partial q_i} = \sum_\alpha m_\alpha \ddot{\mathbf{r}}_\alpha \cdot \frac{\partial \mathbf{r}_\alpha}{\partial q_i}, \quad \text{with } i \in \{1, \cdots, f\}, \tag{D.24}$$

we can introduce a *generalized force* defined by f components, one for every degree of freedom of the system,

$$Q_i \equiv \sum_\alpha \mathbf{F}_\alpha^{\text{ext}} \cdot \frac{\partial \mathbf{r}_\alpha}{\partial q_i}, \quad \text{with } i \in \{1, \cdots, f\}. \tag{D.25}$$

Using the r.h.s. of (D.24) the Q_i can be expressed as

$$Q_i = \frac{d}{dt}\left(\sum_\alpha m_\alpha \dot{\mathbf{r}}_\alpha \cdot \frac{\partial \mathbf{r}_\alpha}{\partial q_i}\right) - \sum_\alpha m_\alpha \dot{\mathbf{r}}_\alpha \cdot \frac{\partial \dot{\mathbf{r}}_\alpha}{\partial q_i}, \tag{D.26}$$

and after substitution of (D.17) this becomes

$$Q_i = \frac{d}{dt}\left(\frac{\partial T}{\partial \dot{q}_i}\right) - \frac{\partial T}{\partial q_i}, \quad \text{with } i \in \{1, \cdots, f\}. \tag{D.27}$$

This expression holds for any holonomic system. It has the structure of a Lagrange equation but the forces remain to be specified. Below we derive the Lagrange equation for three types of forces: (a) conservative or non-conservative potential forces; (b) generalized potential forces; (c) non-potential forces.

(a) If the components of the generalized force can be expressed as the gradients of the potential function $U = U(\mathbf{r}_1, \cdots, \mathbf{r}_N, t)$ we can substitute (D.20) into (D.25) and obtain

$$Q_i \equiv -\sum_\alpha \frac{\partial U}{\partial \mathbf{r}_\alpha} \cdot \frac{\partial \mathbf{r}_\alpha}{\partial q_i} = -\frac{\partial U}{\partial q_i}. \tag{D.28}$$

Substituting this equation into (D.27) and taking into account $\partial U/\partial \dot{q}_i = 0$ (because U does not depend explicitly on the $\dot{q}_i$), the equations of motion takes the form

$$\frac{d}{dt}\frac{\partial \mathcal{L}}{\partial \dot{q}_i} - \frac{\partial \mathcal{L}}{\partial q_i} = 0, \quad \text{with } i \in \{1, \cdots, f\}, \tag{D.29}$$

where

$$\mathcal{L}(\mathbf{q}, \dot{\mathbf{q}}, t) \equiv T(\mathbf{q}, \dot{\mathbf{q}}, t) - U(\mathbf{q}, t). \tag{D.30}$$

The set of equations (D.29) will be referred to as the *Lagrange equations*. Note that in the non-holonomic case we have $f = 3N$ and the set of generalized coordinates $\{q_i\}$ coincides with the full set of cartesian coordinates $\{\mathbf{r}_\alpha\}$; i.e., (D.29) coincides with (D.23).

(b) The derivation of Eq. (D.29) breaks down in cases where $\partial U/\partial \dot{q}_i \neq 0$; i.e., for velocity-dependent forces. However, by construction, the Lagrange equations will still be obtained if the generalized forces can be written the form

$$Q_i = -\frac{\partial U}{\partial q_i} + \frac{d}{dt}\left(\frac{\partial U}{\partial \dot{q}_i}\right), \quad \text{with } i \in \{1, \cdots, f\}. \tag{D.31}$$

Substituting this expression into (D.27) we find

$$\frac{d}{dt}\frac{\partial \mathcal{L}}{\partial \dot{q}_i} - \frac{\partial \mathcal{L}}{\partial q_i} = 0, \quad \text{with } i \in \{1, \cdots, f\}. \tag{D.32}$$

Here the Lagrangian is defined as.

$$\mathcal{L}(\mathbf{q}, \dot{\mathbf{q}}, t) \equiv T(\mathbf{q}, \dot{\mathbf{q}}, t) - U(\mathbf{q}, \dot{\mathbf{q}}, t). \tag{D.33}$$

In the presence of a velocity dependence the function $U = U(\mathbf{q}, \dot{\mathbf{q}}, t)$ is called a *generalized potential function.*

(c) Not all forces can be derived from a potential function. However, also for non-potential forces (for instance friction forces) the equation (D.27) is valid. In the most general case, when both potential and non-potential forces are present, the Lagrange equations can be written in the form

$$\frac{d}{dt}\frac{\partial \mathcal{L}}{\partial \dot{q}_i} - \frac{\partial \mathcal{L}}{\partial q_i} = Q_i, \quad \text{with } i \in \{1, \cdots, f\}. \tag{D.34}$$

Here Q_i are the components of the non-potential force. Forces that can be derived from a potential function are presumed to be contained in the Lagrangian.

D.3.2.1 Motion in a central potential field

As a first example we consider the motion of a particle of mass m freely moving in a *central* potential, $\mathcal{U}(r)$. This is a *conservative* potential which only depends on the distance of the particle to the center of the potential. As the force is central, the orbit will be confined to the plane defined by the position and velocity of the particle at $t = 0$. The Lagrangian is given by

$$\mathcal{L} = \tfrac{1}{2} m\, \dot{\mathbf{r}}^2 - \mathcal{U}(r). \tag{D.35}$$

Choosing the xy plane of a cartesian coordinate system with its origin at the potential center, the position vector given by

$$\mathbf{r} = \hat{\mathbf{x}}\, r\cos\phi + \hat{\mathbf{y}}\, r\sin\phi \tag{D.36}$$

where $\hat{\mathbf{x}}$ and $\hat{\mathbf{y}}$ are the unit vectors along the x and y direction, and (r,ϕ) are the polar coordinates of $\mathbf{r}$. Differentiating Eq. (D.36) with respect to time find for the velocity

$$\dot{\mathbf{r}} = \hat{\mathbf{x}}\,(\dot{r}\cos\phi - r\sin\phi\,\dot{\phi}) + \hat{\mathbf{y}}\,(\dot{r}\sin\phi + r\cos\phi\,\dot{\phi}). \tag{D.37}$$

Then, using the orthogonality of the unit vectors $\hat{\mathbf{x}}$ and $\hat{\mathbf{y}}$ we obtain

$$\dot{\mathbf{r}}^2 = (\dot{r}\cos\phi - r\sin\phi\,\dot{\phi})^2 + (\dot{r}\sin\phi + r\cos\phi\,\dot{\phi})^2 = \dot{r}^2 + r^2\dot{\phi}^2 \tag{D.38}$$

and the Lagrangian becomes

$$\mathcal{L} = \tfrac{1}{2}m\,(\dot{r}^2 + r^2\dot{\phi}^2) - \mathcal{U}(r). \tag{D.39}$$

Since the polar coordinates are obtained from the cartesian coordinates by an orthogonal transformation, both sets of coordinates can serve as a complete set of generalized coordinates on which the action principle is based. In other words, the Lagrange equations also apply to the case of polar coordinates.

For the ϕ motion the Lagrange equation becomes

$$\frac{d}{dt}\frac{\partial\mathcal{L}}{\partial\dot{\phi}} = \frac{\partial\mathcal{L}}{\partial\phi} \quad\Leftrightarrow\quad \frac{d}{dt}\left(mr^2\dot{\phi}\right) = 0. \tag{D.40}$$

This shows that the quantity $mr^2\dot{\phi}$ is *conserved.* In this quantity we recognize the angular momentum about the potential center, $m\,(\mathbf{r}\times\mathbf{v}) = mr^2\dot{\phi}$. Note that this conservation law implies that the area enclosed by the orbit in a given time is conserved in time

$$dA = \tfrac{1}{2}r^2 d\phi = c dt. \tag{D.41}$$

This Keppler's second law. In particular, for a *circular* orbit the angular velocity is conserved: $\dot{\phi} \equiv \omega$ and $\phi = \omega t$ (with the initial phase of the circular motion chosen to be zero at $t = 0$).

For the r motion the Lagrange equation becomes

$$\frac{d}{dt}\frac{\partial\mathcal{L}}{\partial\dot{r}} = \frac{\partial\mathcal{L}}{\partial r} \quad\Leftrightarrow\quad F = \frac{d}{dt}(m\dot{r}) = mr\dot{\phi}^2 - \frac{\partial\mathcal{U}(r)}{\partial r}. \tag{D.42}$$

For a *circular* orbit this reduces to the well-known condition for *stationary* motion,

$$m\omega^2 r - \partial\mathcal{U}(r)/\partial r = 0 \tag{D.43}$$

D.3.2.2 Friction force

In this example we ask for the steady-state velocity of particle falling in a gravitational field in the presence of friction. For a gravitational field along the z axis the potential is $V = \alpha z$. This is a conservative potential field. The friction force is a velocity dependent force,

$$F = -\beta\dot{z}. \tag{D.44}$$

This is a *non-conservative* and therefore *non-Newtonian* force. The Lagrangian is determined only by the kinetic energy and the potential fields (in this case only the gravitational potential),

$$\mathcal{L} = \tfrac{1}{2}\dot{z}^2 - \alpha z. \tag{D.45}$$

Substituting the friction force into the r.h.s. of the Lagrange equation (D.29) we obtain

$$\frac{d}{dt}\frac{\partial\mathcal{L}}{\partial\dot{z}}-\frac{\partial\mathcal{L}}{\partial z}=-\beta\dot{z}. \tag{D.46}$$

Substituting the Lagrangian (D.45) we obtain

$$\ddot{z}+\beta\dot{z}-\alpha=0. \tag{D.47}$$

The steady-state condition is $\ddot{z}=0$; hence, we find for the steady-state velocity

$$\dot{z}=-\alpha/\beta. \tag{D.48}$$

D.3.2.3 Lorentz force

The celebrated example of a velocity-dependent force for which a generalized potential can be defined is the *Lorentz* force. This force governs the motion of a charged particle moving through an electromagnetic field in vacuum. The *Lorentz* force is given by

$$\mathbf{F}=q(\mathbf{E}+\mathbf{v}\times\mathbf{B}), \tag{D.49}$$

where q is the electric charge and $\mathbf{v}=\dot{\mathbf{r}}$ the velocity of the particle. The *generalized electromagnetic potential* from which the Lorentz force may be derived has the form,

$$U(\mathbf{r},\mathbf{v},t)=q(\varphi-\mathbf{v}\cdot\mathbf{A}), \tag{D.50}$$

where $\varphi(\mathbf{r},t)$ and $\mathbf{A}(\mathbf{r},t)$ are the scalar and vector potentials of the electromagnetic field. To demonstrate this assertion we start from (D.31) and find in the vector notation [1]

$$\mathbf{F}(\mathbf{r},\dot{\mathbf{r}},t)=-\partial_{\mathbf{r}}U+\frac{d}{dt}\partial_{\dot{\mathbf{r}}}U=-q[\partial_{\mathbf{r}}\varphi-\partial_{\mathbf{r}}(\dot{\mathbf{r}}\cdot\mathbf{A})+\frac{d}{dt}\partial_{\dot{\mathbf{r}}}(\dot{\mathbf{r}}\cdot\mathbf{A})]. \tag{D.51}$$

Because $\mathbf{A}(\mathbf{r},t)$ does not depend explicitly on $\dot{\mathbf{r}}$ and in view of the vector rule (N.17) the last term of (D.51) can be rewritten as

$$\frac{d}{dt}\partial_{\dot{\mathbf{r}}}(\dot{\mathbf{r}}\cdot\mathbf{A})=\frac{d\mathbf{A}}{dt}=\partial_t\mathbf{A}+(\dot{\mathbf{r}}\cdot\partial_{\mathbf{r}})\mathbf{A}. \tag{D.52}$$

Substitution of this expression into (D.51) we obtain

$$\mathbf{F}=-q[\partial_{\mathbf{r}}\varphi+\partial_t\mathbf{A}+(\dot{\mathbf{r}}\cdot\partial_{\mathbf{r}})\mathbf{A}-\partial_{\mathbf{r}}(\dot{\mathbf{r}}\cdot\mathbf{A})], \tag{D.53}$$

which yields with (N.16) the expression for the Lorentz force

$$\mathbf{F}=-q(\partial_{\mathbf{r}}\varphi+\partial_t\mathbf{A}-\dot{\mathbf{r}}\times\partial_{\mathbf{r}}\times\mathbf{A})=q(\mathbf{E}+\mathbf{v}\times\mathbf{B}). \tag{D.54}$$

D.4 The Lagrange formalism

In Section D.3 the Lagrange equations were derived from the Newton equations of motion together with the principle of d'Alembert. An alternative approach is to derive the Lagrange equations from the *principle of Hamilton.* In this approach we start by noting that the time evolution of the system corresponds to a unique *path* of the vector $\mathbf{q}\equiv(q_1,\cdots,q_f)$ in the f-dimensional configuration space of the generalized coordinates. As these coordinates are mutually independent, this path can be predicted over an infinitesimal time interval from t to $t+\delta t$ by the relation

$$\mathbf{q}(t+\delta t)=\mathbf{q}(t)+\dot{\mathbf{q}}(t)\delta t. \tag{D.55}$$

Hence, to predict the continuation of the path at time t, *both* $\mathbf{q}(t)$ and $\dot{\mathbf{q}}(t)$ have to be known. In other words, together $\mathbf{q}$ and $\dot{\mathbf{q}}$ fully determine the *classical state* of the system (often represented by a point in the so-called *phase space* of position and momentum).

---

[1] In this example we use the short-hand notation $\partial_{\mathbf{q}}\equiv\partial/\partial\mathbf{q}\equiv(\partial/\partial q_x,\partial/\partial q_y,\partial/\partial q_z)$ and $\partial_t\equiv\partial/\partial t$.

D.4.1 Principle of Hamilton

Let us consider the case where the *actual* path $\mathbf{q}(t)$ runs from the starting point $\mathbf{q}(t_0)$ to the end point $\mathbf{q}(t_1)$ during the time interval (t_0, t_1), and let $\mathbf{q}'(t)$ be some *adjacent* path, slightly differing from the actual path but with the same starting point and end point. The key idea behind the principle of Hamilton is that any continuous deviation from the actual path,

$$\delta\mathbf{q}(t) = \mathbf{q}'(t) - \mathbf{q}(t), \tag{D.56}$$

with boundary conditions

$$\delta\mathbf{q}(t_0) = 0 \quad \text{and} \quad \delta\mathbf{q}(t_1) = 0, \tag{D.57}$$

has to be unfavorable in some respect. Thus we search for a functional of $\mathbf{q}$ and $\dot{\mathbf{q}}$ (the *cost functional* of the variational problem) which is minimal for the actual path from $\mathbf{q}(t_0)$ to $\mathbf{q}(t_1)$. Minimizing this functional with respect to the path provides us with criteria that have to be satisfied along the actual path (for instance conservation laws). This cost functional is called the *action* and is given by the integral of a lagrangian function $\mathcal{L}(\mathbf{q}, \dot{\mathbf{q}}, t)$ over the time interval (t_0, t_1),

$$S = \int_{t_0}^{t_1} \mathcal{L}(\mathbf{q}, \dot{\mathbf{q}}, t)dt. \tag{D.58}$$

Whatever this "Lagrangian" may turn out to be, the expression for the action is plausible; at each point in time t within the interval (t_0, t_1), knowledge of $\mathbf{q}$ and $\dot{\mathbf{q}}$ suffice to determine the actual path from $\mathbf{q}(t_0)$ to $\mathbf{q}(t_1)$. So if the Lagrangian is to be deterministic for the actual path, it can only be a function of the variables $\mathbf{q}$, $\dot{\mathbf{q}}$ and t. This minimization procedure is called the *action principle*[1]or the *principle of Hamilton.*

The principle of Hamilton is a variational principle that enables us to derive properties of the Lagrangian for systems in which the function $\mathcal{L}(\mathbf{q}, \dot{\mathbf{q}}, t)$ is at least twice differentiable; i.e., *smooth* with respect to the variables $\mathbf{q}$, $\dot{\mathbf{q}}$ and t. Fortunately, many systems fall in this class and we shall study some examples. Let us consider the change in action of such a system over the time interval (t_0, t_1) when deforming the path defined by $\mathbf{q}(t)$ and $\dot{\mathbf{q}}(t)$ into an adjacent smooth continuous path $\mathbf{q}'(t)$ and $\dot{\mathbf{q}}'(t)$ given by $\mathbf{q}' = \mathbf{q} + \delta\mathbf{q}$ and $\dot{\mathbf{q}}' = \dot{\mathbf{q}} + \delta\dot{\mathbf{q}}$,

$$\delta S = \int_{t_0}^{t_1} [\mathcal{L}(\mathbf{q} + \delta\mathbf{q}, \dot{\mathbf{q}} + \delta\dot{\mathbf{q}}, t) - \mathcal{L}(\mathbf{q}, \dot{\mathbf{q}}, t)]dt. \tag{D.59}$$

As the Lagrangian is smooth we can use a Taylor expansion with respect to $\delta\mathbf{q}$ and $\delta\dot{\mathbf{q}}$,[2]

$$\mathcal{L}(\mathbf{q} + \delta\mathbf{q}, \dot{\mathbf{q}} + \delta\dot{\mathbf{q}}, t) = \mathcal{L}(\mathbf{q}, \dot{\mathbf{q}}, t) + \frac{\partial\mathcal{L}}{\partial\mathbf{q}} \cdot \delta\mathbf{q} + \frac{\partial\mathcal{L}}{\partial\dot{\mathbf{q}}} \cdot \delta\dot{\mathbf{q}} + \cdots, \tag{D.60}$$

and the change of action takes the form

$$\delta S = \int_{t_0}^{t_1} \sum_i \left(\frac{\partial\mathcal{L}}{\partial q_i}\delta q_i + \frac{\partial\mathcal{L}}{\partial\dot{q}_i}\delta\dot{q}_i \right) dt. \tag{D.61}$$

By partial integration of the second term this integral becomes

$$\delta S = \sum_i \left[\frac{\partial\mathcal{L}}{\partial\dot{q}_i}\delta q_i \right]_{t_0}^{t_1} + \int_{t_0}^{t_1} \sum_i \left(\frac{\partial\mathcal{L}}{\partial q_i} - \frac{d}{dt}\frac{\partial\mathcal{L}}{\partial\dot{q}_i} \right) \delta q_i dt. \tag{D.62}$$

---

[1] Traditionally the action principle is called the *priciple of least action.* This is an unfortunate name because the variational method provides stationary points rather than minima.

[2] Note the following equivalent notations for the gradient operator, $\partial_{\mathbf{q}} \equiv \partial/\partial\mathbf{q} \equiv (\partial/\partial q_1, \cdots, \partial/\partial q_f)$.

Since the variation is zero at the boundaries of the path, see (D.57), this expression reduces to

$$\delta S = \int_{t_0}^{t_1} \sum_i \left(\frac{\partial \mathcal{L}}{\partial q_i} - \frac{d}{dt}\frac{\partial \mathcal{L}}{\partial \dot{q}_i} \right) \delta q_i dt. \tag{D.63}$$

At this point we can formulate a necessary condition for minimal action: the functional must be stationary ($\delta S = 0$) under *arbitrary* variations of the path,[1]

$$\int_{t_0}^{t_1} \sum_i \left(\frac{\partial \mathcal{L}}{\partial q_i} - \frac{d}{dt}\frac{\partial \mathcal{L}}{\partial \dot{q}_i} \right) \delta q_i dt = 0. \tag{D.64}$$

Since the variations δq_i are independent this condition is only satisfied if all terms of the summation vanish simultaneously,

$$\frac{\partial \mathcal{L}}{\partial q_i} - \frac{d}{dt}\frac{\partial \mathcal{L}}{\partial \dot{q}_i} = 0, \quad \text{with } i \in \{1, \cdots, f\}. \tag{D.65}$$

These equations constitute the *Euler-Lagrange equations* of the action variational principle in which we recognize the *Lagrange equations* of classical mechanics. In Section D.3 these were obtained starting from the principle of d'Alembert.

The action principle has revealed the Lagrangian as the optimal functional from which the laws of physics of a mechanical of the system can be derived. As the Lagrangian is optimized by variation of the path in phase space it is independent of the choice of coordinates. The latter also holds for the form of the Lagrange equations.

Properties of the Lagrangian

Above the Lagrangian $\mathcal{L}(\mathbf{q}, \dot{\mathbf{q}}, t)$ is introduced as a smooth (at least twice differentiable) function of the variables, $\mathbf{q}$, $\dot{\mathbf{q}}$ and t for which the action is stationary under the condition that the Lagrange equations (D.65) are satisfied. Lagrangians have the following properties:

(a) *Additive property*: The Lagrangian $\mathcal{L}$ of a system consisting of two non-interacting subsystems can be written as the sum of the Lagrangians $\mathcal{L}_1$ and $\mathcal{L}_2$ of the two subsystems,

$$\mathcal{L} = \mathcal{L}_1 + \mathcal{L}_2. \tag{D.66}$$

This has to be the case because the paths of the subsystems in configuration space can be varied independently. Hence, the least action of the total system must coincide with the sum of the least actions of the two subsystems.

(b) *Definition up to a multiplicative factor*: The path of least action is invariant under multiplication of the Lagrangian by an arbitrary constant. For $\mathcal{L}' = \alpha\mathcal{L}$ we find

$$S' = \alpha \int_{t_0}^{t_1} \mathcal{L}(\mathbf{q}, \dot{\mathbf{q}}, t) dt = \alpha S. \tag{D.67}$$

Hence, $\delta S' = \alpha \delta S$, which implies that the condition $\delta S' = 0$ is equivalent to $\delta S = 0$. This means that the multiplication by α does not affect the stationarity condition and leads to the same Euler-Lagrange equation.

(c) *Definition up to a total time derivative*: The path of least action is invariant under addition of a total time derivative to the Lagrangian. For $\mathcal{L}' = \mathcal{L} + df/dt$ we find

$$S' = \int_{t_0}^{t_1} \mathcal{L}(\mathbf{q}, \dot{\mathbf{q}}, t) dt + \int_{t_0}^{t_1} \frac{d\mathrm{f}}{dt} dt = S + \mathrm{f}(t_1) - \mathrm{f}(t_0). \tag{D.68}$$

---

[1] Note that the inverse is not generally true: being stationary does not mean that the action is minimal.

Hence, S' and S differ by a constant and this does not affect the variation, $\delta S' = \delta S$. Thus, the addition of $d\alpha/dt$ does not change the stationarity condition and leads to the same Euler-Lagrange equation.

D.4.2 Lagrangian of a free particle

To gain insight in the functional form of the Lagrangian we consider a free particle. In classical mechanics space and time are postulated to be homogeneous, so the Lagrangian of the particle (which determines the time evolution of the system) must be independent of position $\mathbf{r}$ and time t. This leaves the velocity $\mathbf{v} = \dot{\mathbf{r}}$ as the only variable, $\mathcal{L} = \mathcal{L}(\mathbf{v})$. Since $\mathcal{L}$ is independent of $\mathbf{r}$ we have $\partial\mathcal{L}/\partial\mathbf{r} = 0$ and the Lagrange equation (D.65) becomes

$$\frac{d}{dt}\frac{\partial\mathcal{L}}{\partial\mathbf{v}} = 0. \tag{D.69}$$

Hence, $\partial\mathcal{L}/\partial\mathbf{v}$ must be a constant and since $\mathbf{v}$ is the only variable of $\mathcal{L}$ the velocity must be constant, $\mathbf{v}(t) = \mathbf{v}_0$. Thus we found *Newton's law of inertia.*

Space is postulated to be isotropic. Thus, the Lagrangian may only depend on the absolute value of the velocity, v; i.e., it has to be some function of the velocity squared,

$$\mathcal{L} = \mathcal{L}(v^2). \tag{D.70}$$

This observation immediately implies that the Lagrangian is invariant under time reversal; i.e., time is isotropic in newtonian mechanics. To get more precise information about the functional dependence of $\mathcal{L}$ on v^2 we turn to *Galileo's principle of relativity*, which is also based on the homogeneity and isotropy of space and time. According to this principle the equations of motion (hence also the Lagrangian) must be *invariant under a Galilean transformation*, which is a transformation of one inertial frame to another (from the inertial frame $\mathcal{S}$ to the frame $\mathcal{S}'$)

$$\mathbf{r}' = \mathbf{r} + \mathbf{V}t; \qquad t' = t, \tag{D.71}$$

where $\mathbf{V}$ is the relative velocity of the frame $\mathcal{S}'$ with respect to the frame $\mathcal{S}$. Thus we are led to compare two Lagrangians, $\mathcal{L}(v'^2)$ and $\mathcal{L}(v^2)$, defined with respect to two inertial frames which move with an infinitesimally small but *constant* velocity $\mathbf{w} = \mathbf{v}' - \mathbf{v}$ with respect to each other. Using the relation $v'^2 = v^2 + 2\mathbf{v}\cdot\mathbf{w} + w^2$ we find

$$\mathcal{L}(v'^2) = \mathcal{L}(v^2) + \frac{\partial\mathcal{L}}{\partial v^2}(2\mathbf{v}+\mathbf{w})\cdot\mathbf{w} + \frac{\partial^2\mathcal{L}}{\partial(v^2)^2}\left[(2\mathbf{v}+\mathbf{w})\cdot\mathbf{w}\right]^2 + \cdots . \tag{D.72}$$

As the time evolution of the system must be independent of the choice of inertial frame, the two Lagrangians must be equivalent. In view of property (D.68) this means that they cannot differ by more than a total time derivative. Since $\mathbf{v}$ is by definition a total time derivative and $\mathbf{w}$ a constant, $\partial\mathcal{L}/\partial v^2$ has to be a constant; i.e., the function $\mathcal{L}$ has to be a linear function of v^2,

$$\mathcal{L} = \mathcal{L}_0 + \alpha v^2. \tag{D.73}$$

For any other functional dependence on v^2 the Lagrangian is either trivially zero or differs from $\mathcal{L}$ by more than a total time derivative. Once we accept that $\mathcal{L}$ has to be a linear function of v^2 we find that all higher order terms of the expansion vanish. As the constant $\mathcal{L}_0$ can also be regarded as a total time derivative we may write the Lagrangian as simply proportional to v^2,

$$\mathcal{L} = \tfrac{1}{2}mv^2 = T. \tag{D.74}$$

The proportionality constant m is called the *mass* of the particle and serves to calibrate the Lagrangian. This calibration is possible in view of property (D.67). The chosen calibration yields the *kinetic energy* of the particle, $T = \frac{1}{2}mv^2$.

For a free particle the principle of least action is very intuitive. The particle has to follow a straight path in configuration space (which coincides in this case with real space) because for a constant Lagrangian any deviation from a straight path leads to an increase of the action integral. The example also shows that the mass must be positive ($m > 0$) because otherwise the action could be reduced by deviating from the straight path, which contradicts experimental observation.

D.4.3 Lagrangian of a single particle in a potential field

Let us now add to the kinetic energy of the particle a (smooth) function of position and time (i.e., a time-dependent field),

$$\mathcal{L}(\mathbf{r}, \dot{\mathbf{r}}, t) = \tfrac{1}{2}mv^2 - U(\mathbf{r}, t). \tag{D.75}$$

Being a function of $\mathbf{r}$, $\dot{\mathbf{r}}$ and t, the new expression is again a Lagrangian if the Lagrange equations are satisfied:

$$\frac{\partial \mathcal{L}}{\partial \mathbf{r}} = \frac{d}{dt}\frac{\partial \mathcal{L}}{\partial \mathbf{v}}. \tag{D.76}$$

When will this be the case? Since $U(\mathbf{r}, t)$ is independent of $\mathbf{v}$ and $T = \frac{1}{2}m\mathbf{v}^2$ is independent of $\mathbf{r}$ and t, substitution of (D.75) into the Lagrange equations (D.76) leads to the following condition

$$-\frac{\partial U}{\partial \mathbf{r}} = \frac{d}{dt}\frac{\partial T}{\partial \mathbf{v}} = m\frac{d\mathbf{v}}{dt}. \tag{D.77}$$

Interpreting the negative gradient of $U(\mathbf{r}, t)$ as a force,

$$\mathbf{F} = -\frac{\partial U}{\partial \mathbf{r}} \tag{D.78}$$

we recognize in (D.77) *Newton's second law*, $\mathbf{F} = m\ddot{\mathbf{r}}$. Hence, the Lagrange equations are satisfied if the particle moves in accordance with the Newton equations of motion; i.e., under non-relativistic conditions. The function $U(\mathbf{r}, t)$ is called the *potential field* of the system. If this field does not depend on position, $U(\mathbf{r}, t) = U(t)$, it is called *uniform.* If it does not depend on time, $U(\mathbf{r}, t) = U(\mathbf{r})$, the field is called *conservative.*

D.4.3.1 Generalized potential functions

The above discussion can be generalized to include velocity-dependent potentials, called *generalized potential functions.* For this purpose we add to the kinetic energy a (smooth) function of $\mathbf{r}$, $\dot{\mathbf{r}}$ and t,

$$\mathcal{L}(\mathbf{r}, \dot{\mathbf{r}}, t) = \tfrac{1}{2}mv^2 - U(\mathbf{r}, \dot{\mathbf{r}}, t). \tag{D.79}$$

This function is a Lagrangian if it satisfies the Lagrange equations. Substituting $\mathcal{L}(\mathbf{r}, \dot{\mathbf{r}}, t)$ into (D.76), we find that the condition (D.77) is replaced by

$$-\frac{\partial U}{\partial \mathbf{r}} + \frac{d}{dt}\frac{\partial U}{\partial \mathbf{v}} = \frac{d}{dt}\frac{\partial T}{\partial \mathbf{v}}. \tag{D.80}$$

In other words, the Lagrange equations are satisfied for *generalized forces* of the type

$$\mathbf{Q} = -\frac{\partial U}{\partial \mathbf{r}} + \frac{d}{dt}\frac{\partial U}{\partial \mathbf{v}}. \tag{D.81}$$

Note that (D.81) reduces to (D.78) for velocity-independent potentials; hence, the class of generalized forces includes gradient forces as a subclass. Although any generalized potential function gives rise to a generalized force, the inverse is *not* true. For instance, friction forces, $\mathbf{F} = -\alpha\mathbf{v}$, cannot be expressed in the form (D.81). On the other hand, the Lorentz force is an example of a generalized force because we can define a generalized potential function for which (D.81) is satisfied (see Problem D.2).

Problem D.2. Show, using the Einstein notation, that the Lorentz force, $F_i = q[E_i + (\mathbf{v}\times\mathbf{B})_i]$, is the generalized force resulting from the generalized potential function $U = q(\varphi - v_j \cdot A_j)$, where $\varphi(\mathbf{r},t)$ is the scalar and $\mathbf{A}(\mathbf{r},t)$ the vector potential. Further, $E_i = -\partial_i\varphi - \partial_t A_i$ and $B_i = \varepsilon_{ijk}\partial_j A_k$ are the cartesian components of the (generally time dependent) $\mathbf{E}$ and $\mathbf{B}$ fields, respectively. Use the short-hand notation $\partial_i \equiv \partial/\partial r_i$ and $\partial_t \equiv \partial/\partial t$.

Solution. The first term of (D.81) yields

$$-\partial_i U = q\left[-\partial_i\varphi - v_j\partial_i A_j(\mathbf{r},t)\right] \tag{a}$$

and the second term can be written as

$$\frac{d}{dt}\frac{\partial U}{\partial v_i} = q\frac{d}{dt}\left(\frac{\partial\varphi(\mathbf{r},t)}{\partial v_i} - \frac{\partial v_j A_j(\mathbf{r},t)}{\partial v_i}\right) = -q\frac{d}{dt}A_i(\mathbf{r},t) = q\left[-\partial_j A_i(\mathbf{r},t)\,\dot{r}_j - \partial_t A_i(\mathbf{r},t)\right]. \tag{b}$$

Combining (a) and (b) we obtain for the generalized force

$$Q_i = q\left[-\partial_i\varphi - \partial_t A_i + v_j\partial_i A_j - v_j\partial_j A_i\right]. \tag{c}$$

In the first two terms within the brackets we recognize the E_i-component of the $\mathbf{E}$ field. Likewise, recalling $\mathbf{B} = \boldsymbol{\nabla}\times\mathbf{A}$, we recognize in the last two terms the component $(\mathbf{v}\times\mathbf{B})_i$ of the $\mathbf{v}\times\mathbf{B}$ field[1]

$$(\mathbf{v}\times\mathbf{B})_i = \varepsilon_{ijk}v_j(\boldsymbol{\nabla}\times\mathbf{A})_k = \varepsilon_{ijk}\varepsilon_{klm}v_j\partial_l A_m = v_j\partial_i A_j - v_j\partial_j A_i.$$

Hence, Eq. (c) can be rewritten as $Q_i = q\left[E_i + (\mathbf{v}\times\mathbf{B})_i\right]$, which is indeed the expression for the Lorentz force. ☐

D.5 Many-particle systems

D.5.1 Lagrangian

At this point we return to many-particle systems. In view of property (D.66) we know that the Lagrangian of a system of N *non*-interacting particles is given by

$$\mathcal{L} = \tfrac{1}{2}\sum_\alpha m_\alpha v_\alpha^2, \tag{D.82}$$

where $\alpha \in \{1,\cdots N\}$. In search for the Lagrangian in the presence of interactions between the particles as well as interactions with the environment we use a procedure similar to the one introduced for the single particle: we add to the Lagrangian (D.82) a generalized potential function

$$\mathcal{L}(\cdots,\mathbf{r}_\alpha,\dot{\mathbf{r}}_\alpha,\cdots,t) = \tfrac{1}{2}\sum_\alpha m_\alpha\dot{\mathbf{r}}_\alpha^2 - U(\cdots,\mathbf{r}_\alpha,\dot{\mathbf{r}}_\alpha,\cdots,t). \tag{D.83}$$

The potential function depends in principle on the position and velocities of *all* the particles as well as on time

$$U(\cdots,\mathbf{r}_\alpha,\dot{\mathbf{r}}_\alpha,\cdots,t) = U^{int}(\cdots,\mathbf{r}_\alpha,\dot{\mathbf{r}}_\alpha,\cdots) + U^{ext}(\cdots,\mathbf{r}_\alpha,\dot{\mathbf{r}}_\alpha,\cdots,t). \tag{D.84}$$

The function U^{int} is called the *internal* generalized potential function and represents the interaction between all particles of the system; *e.g.*, the Van der Waals interaction between the atoms in a classical gas. The function U^{ext} is called the *external* generalized potential function and represents externally applied fields; *e.g.*, the electromagnetic potential of a light field.

The function (D.83) is a Lagrangian if it satisfies the Lagrange equations,

$$\frac{\partial\mathcal{L}}{\partial\mathbf{r}_\alpha} = \frac{d}{dt}\frac{\partial\mathcal{L}}{\partial\mathbf{v}_\alpha}, \quad \text{with } \alpha\in\{1,\cdots N\}. \tag{D.85}$$

---

[1] In the Einstein notation the contraction of the Levi-Civita tensor is given by $\varepsilon_{ijk}\varepsilon_{klm} = \delta_{il}\delta_{jm} - \delta_{im}\delta_{jl}$.

Since the first term on the r.h.s. of (D.83) is independent of $\mathbf{r}_\alpha$ we find that the condition (D.85) can be written in the form

$$-\frac{\partial U}{\partial \mathbf{r}_\alpha}+\frac{d}{dt}\frac{\partial U}{\partial \mathbf{v}_\alpha}=\frac{d}{dt}\frac{\partial T}{\partial \mathbf{v}_\alpha}=m_\alpha \ddot{\mathbf{r}}_\alpha, \quad \text{with } \alpha\in\{1,\cdots N\}. \tag{D.86}$$

Hence, the quantity

$$\mathbf{Q}_\alpha=-\frac{\partial U}{\partial \mathbf{r}_\alpha}+\frac{d}{dt}\frac{\partial U}{\partial \mathbf{v}_\alpha}, \quad \text{with } \alpha\in\{1,\cdots N\}, \tag{D.87}$$

can be interpreted as the generalized force acting on particle α as the result of its interaction with all other particles in the system.

Generalization to the presence of scleronomous constraints

It is straightforward to generalize the formalism to holonomic systems with *scleronomous* constraints. In this case the positions $\mathbf{r}_\alpha$ and velocities $\dot{\mathbf{r}}_\alpha$ of the particles can be expressed in terms of $f=3N-l$ generalized coordinates $q_1,\cdots,q_f$ and velocities $\dot{q}_1,\cdots,\dot{q}_f$,

$$\mathbf{r}_\alpha=\mathbf{r}_\alpha(q_1,\cdots,q_f) \tag{D.88a}$$

$$\dot{\mathbf{r}}_\alpha=\sum_{i=1}^{f}\frac{\partial \mathbf{r}_\alpha}{\partial q_i}\dot{q}_i. \tag{D.88b}$$

Substituting these expressions into (D.83) we obtain

$$\mathcal{L}(\mathbf{q},\dot{\mathbf{q}})=\tfrac{1}{2}\sum_{i,j=1}^{f}a_{ij}(\mathbf{q})\dot{q}_i\dot{q}_j-U(\mathbf{q},\dot{\mathbf{q}}). \tag{D.89}$$

Here we use the vector notation (D.18); the coefficient $a_{ij}(\mathbf{q})$ is given by

$$a_{ij}(\mathbf{q})=\sum_\alpha m_\alpha\frac{\partial \mathbf{r}_\alpha}{\partial q_i}\frac{\partial \mathbf{r}_\alpha}{\partial q_j}. \tag{D.90}$$

In terms of the generalized coordinates and velocities the Lagrange equation take the form

$$\frac{\partial \mathcal{L}}{\partial q_i}=\frac{d}{dt}\frac{\partial \mathcal{L}}{\partial \dot{q}_i}, \quad \text{with } i\in\{1,\cdots f\}, \tag{D.91}$$

and the components of the generalized force become

$$Q_i=-\frac{\partial U}{\partial q_i}+\frac{d}{dt}\frac{\partial U}{\partial \dot{q}_i}, \quad \text{with } i\in\{1,\cdots f\}. \tag{D.92}$$

Note that in the absence of constraints we have $f=3N$ and the generalized coordinates turn into the cartesian coordinates of the particles, $(q_1,\cdots,q_f)\to(x_1,y_1,z_1,\cdots,x_N,y_N,z_N)$, and we regain (D.85) and (D.87).

Open and closed systems

A mechanical system is called *closed* if it does not interact with its environment; i.e., the potential function can be written as $U=U^{int}(\cdots,\mathbf{r}_\alpha,\dot{\mathbf{r}}_\alpha,\cdots)$. Hence, for closed systems both the potential function and the Lagrangian are time independent. An example of a closed mechanical system is an atom in field-free space. If the system is not closed it is called open. An example of an *open* system is a cloud of interacting particles confined by an external potential.

D.5.2 Energy conservation

In the absence of *time-dependent* external forces the evolution of a mechanical system only depends on the state of that system and not on the instant that this state is created in time. In view of this *homogeneity of time* the Lagrangian of such a system cannot depend explicitly on time; i.e., the total time derivative of (D.83) can be written in the form

$$\frac{d\mathcal{L}}{dt} = \sum_\alpha \frac{\partial \mathcal{L}}{\partial \mathbf{r}_\alpha} \cdot \dot{\mathbf{r}}_\alpha + \sum_\alpha \frac{\partial \mathcal{L}}{\partial \dot{\mathbf{r}}_\alpha} \cdot \ddot{\mathbf{r}}_\alpha. \tag{D.93}$$

With the aid of the Lagrange equation (D.85) this becomes

$$\frac{d\mathcal{L}}{dt} = \sum_\alpha \dot{\mathbf{r}}_\alpha \cdot \frac{d}{dt}\frac{\partial \mathcal{L}}{\partial \dot{\mathbf{r}}_\alpha} + \sum_\alpha \ddot{\mathbf{r}}_\alpha \cdot \frac{\partial \mathcal{L}}{\partial \dot{\mathbf{r}}_\alpha} = \sum_\alpha \frac{d}{dt}\left(\dot{\mathbf{r}}_\alpha \cdot \frac{\partial \mathcal{L}}{\partial \dot{\mathbf{r}}_\alpha}\right). \tag{D.94}$$

Rewriting this expression in the form

$$\frac{d}{dt}\left(\sum_\alpha \dot{\mathbf{r}}_\alpha \cdot \frac{\partial \mathcal{L}}{\partial \dot{\mathbf{r}}_\alpha} - \mathcal{L}\right) = 0 \tag{D.95}$$

we find that the quantity

$$E = \sum_\alpha \dot{\mathbf{r}}_\alpha \cdot \frac{\partial \mathcal{L}}{\partial \dot{\mathbf{r}}_\alpha} - \mathcal{L} \tag{D.96}$$

is a *constant of the motion*; i.e., it is *conserved* along the path from t_0 to t_1. This quantity is called the *energy* of the system. Mechanical systems for which the energy is conserved are called *conservative* systems. It is straightforward to generalize (D.96) to holonomic systems with *scleronomous* constraints,

$$E(\mathbf{q}, \dot{\mathbf{q}}) = \sum_i \dot{q}_i \frac{\partial \mathcal{L}}{\partial \dot{r}_i} - \mathcal{L}. \tag{D.97}$$

D.5.2.1 Potential energy

The energy of a *conservative* system can always be written as the sum of a *kinetic energy* and a *potential energy* contribution. This can be seen as follows. The kinetic energy is uniquely determined by the velocities of the particles,

$$T(\dot{\mathbf{r}}_1, \cdots, \dot{\mathbf{r}}_N) = \tfrac{1}{2}\sum_\alpha m_\alpha v_\alpha^2.$$

In general this quantity will change in time under the influence of inter-particle forces but (since the system is conservative) the (total) energy has to remain constant, $E(\mathbf{r}_1, \cdots, \mathbf{r}_N, \dot{\mathbf{r}}_1, \cdots, \dot{\mathbf{r}}_N) = E$. Since the same kinetic energy can be obtained for different distributions of velocity over the particles the difference of E and T has to be a function of the positions *only.* This difference is called the *potential energy* $V(\mathbf{r}_1, \cdots, \mathbf{r}_N)$ of the system,

$$V(\mathbf{r}_1, \cdots, \mathbf{r}_N) = E(\mathbf{r}_1, \cdots, \mathbf{r}_N, \dot{\mathbf{r}}_1, \cdots, \dot{\mathbf{r}}_N) - T(\dot{\mathbf{r}}_1, \cdots, \dot{\mathbf{r}}_N). \tag{D.98}$$

Beware of the difference between the potential energy $V(\mathbf{r}_1, \cdots, \mathbf{r}_N)$ and the generalized potential function $U(\mathbf{r}_1, \cdots, \mathbf{r}_N, \dot{\mathbf{r}}_1, \cdots, \dot{\mathbf{r}}_N)$; the former determines the kinetic energy of a conservative system (also in the presence of generalized forces between the particles); the latter determines the force on all particles, both for conservative and non-conservative systems.

An *open* mechanical system is conservative if the external potential is constant in time.

D.5.3 Momentum conservation in closed systems

The evolution of a *closed* mechanical system only depends on the internal state of that system and not on the absolute position where this state is created in space. In view of this *homogeneity of space* the Lagrangian of a closed system must be independent of the absolute position of that system; i.e., (D.83) must be invariant under a translation of the system over a distance $\mathbf{R}$,

$$\mathbf{r}'_\alpha = \mathbf{r}_\alpha + \mathbf{R}. \tag{D.99}$$

Thus we are led to compare two Lagrangians, defined with respect to two inertial frames shifted with respect to each other over an infinitesimally small distance $\delta\mathbf{r}_\alpha = \mathbf{r}'_\alpha - \mathbf{r}_\alpha = \delta\mathbf{R}$. For this displagrangianlacement the change change in Lagrangian is given by

$$\delta\mathcal{L} = \sum_\alpha \frac{\partial\mathcal{L}}{\partial\mathbf{r}_\alpha} \cdot \delta\mathbf{R} + \cdots . \tag{D.100}$$

Hence, a necessary condition that the Lagrangian be invariant under an *arbitrary* small shift $\delta\mathbf{R}$ is

$$\sum_\alpha \frac{\partial\mathcal{L}}{\partial\mathbf{r}_\alpha} = 0. \tag{D.101}$$

Note that also the sum over all higher order terms has to vanish but this has no relevance in the present context. Using the Lagrange equation (D.85) the condition (D.101) becomes

$$\sum_\alpha \frac{\partial\mathcal{L}}{\partial\mathbf{r}_\alpha} = \frac{d}{dt}\sum_\alpha \frac{\partial\mathcal{L}}{\partial\mathbf{v}_\alpha} = 0. \tag{D.102}$$

Apparently, in a closed system the quantity

$$\mathbf{P} = \sum_\alpha \mathbf{p}_\alpha \tag{D.103}$$

with

$$\mathbf{p}_\alpha = \frac{\partial\mathcal{L}}{\partial\dot{\mathbf{r}}_\alpha} \tag{D.104}$$

is a *constant of the motion.* The quantity $\mathbf{P}$ is called the *canonical momentum* of the system and $\mathbf{p}_\alpha$ is the canonical momentum of particle α. Hence, for closed systems the canonical momenta of the individual particles always add up to the total momentum of the system, irrespective of the absence or presence of generalized forces between the particles. With (D.85) it immediately follows that

$$\dot{\mathbf{p}}_\alpha = \frac{\partial\mathcal{L}}{\partial\mathbf{r}_\alpha}. \tag{D.105}$$

Example: velocity-independent potential functions

In the special case of systems with only *velocity-independent* interactions between the particles (e.g., gravitational forces) the canonical momentum only depends on the kinetic energy and we find the well-known expression

$$\mathbf{p}_\alpha = m_\alpha \mathbf{v}_\alpha. \tag{D.106}$$

The Hamiltonian is given by

$$E = \sum_\alpha m_\alpha \mathbf{v}_\alpha^2 - \mathcal{L}, \tag{D.107}$$

which becomes after substitution of the Lagrangian (D.83)

$$E = T + V. \tag{D.108}$$

D.5.3.1 Generalization to holonomic systems with scleronomous constraints - symmetry

It is straightforward to generalize (D.104) and (D.105) to *holonomic* systems with *scleronomous* constraints,

$$p_i = \frac{\partial \mathcal{L}}{\partial \dot{q}_i} \tag{D.109a}$$

$$\dot{p}_i = \frac{\partial \mathcal{L}}{\partial q_i} \tag{D.109b}$$

with $i \in \{1, \cdots f\}$.

D.5.4 Conservation of angular momentum in closed systems

In view of the *isotropy of space* the Lagrangian of a *closed* system must be independent of the absolute orientation of that system; i.e., (D.83) must be invariant under rotation of the system over an angle $\boldsymbol{\Omega}$ about an axis in direction $\hat{\boldsymbol{\Omega}}$ through the origin of the inertial frame of observation,

$$\mathbf{r}'_\alpha = \mathbf{r}_\alpha + \boldsymbol{\Omega} \times \mathbf{r}_\alpha. \tag{D.110}$$

Under such a rotation also the velocity vector changes direction

$$\mathbf{v}'_\alpha = \mathbf{v}_\alpha + \boldsymbol{\Omega} \times \mathbf{v}_\alpha. \tag{D.111}$$

Thus we are led to compare two Lagrangians, defined with respect to two inertial frames rotated with respect to each other over an infinitesimally small angle $\delta\boldsymbol{\Omega}$ so that $\delta\mathbf{r}_\alpha = \mathbf{r}'_\alpha - \mathbf{r}_\alpha = \delta\boldsymbol{\Omega} \times \mathbf{r}_\alpha$ and $\delta\mathbf{v}_\alpha = \mathbf{v}'_\alpha - \mathbf{v}_\alpha = \delta\boldsymbol{\Omega} \times \mathbf{v}_\alpha$. For this rotation we have

$$\delta\mathcal{L} = \sum_\alpha \frac{\partial \mathcal{L}}{\partial \mathbf{r}_\alpha} \cdot \delta\boldsymbol{\Omega} \times \mathbf{r}_\alpha + \sum_\alpha \frac{\partial \mathcal{L}}{\partial \dot{\mathbf{r}}_\alpha} \cdot \delta\boldsymbol{\Omega} \times \dot{\mathbf{r}}_\alpha + \cdots . \tag{D.112}$$

Hence, a necessary condition that the Lagrangian be invariant under an *arbitrary* rotation (about an axis through the origin) is

$$\sum_\alpha \left(\mathbf{r}_\alpha \times \frac{\partial \mathcal{L}}{\partial \mathbf{r}_\alpha} + \dot{\mathbf{r}}_\alpha \times \frac{\partial \mathcal{L}}{\partial \dot{\mathbf{r}}_\alpha} \right) = 0. \tag{D.113}$$

Here we used the permutation rules for the vector products (see Appendix N). Turning to canonical variables the condition becomes

$$\sum_\alpha (\mathbf{r}_\alpha \times \dot{\mathbf{p}}_\alpha + \dot{\mathbf{r}}_\alpha \times \mathbf{p}_\alpha) = \frac{d}{dt} \sum_\alpha (\mathbf{r}_\alpha \times \mathbf{p}_\alpha) = 0. \tag{D.114}$$

Apparently, in a closed system the quantity

$$\mathbf{L} = \sum_\alpha (\mathbf{r}_\alpha \times \mathbf{p}_\alpha), \tag{D.115}$$

with

$$\mathbf{L}_\alpha \equiv \mathbf{r}_\alpha \times \mathbf{p}_\alpha, \tag{D.116}$$

is a constant of the motion. The quantity $\mathbf{L}$ is called the *angular momentum* of the system and $\mathbf{L}_\alpha$ is the angular momentum of particle α, both with respect to the origin of the inertial system. Although the value of $\mathbf{L}$ depends on the choice of origin, the conservation holds irrespective of this choice.

D.6 The Hamilton formalism

In the Lagrange formalism the dynamical evolution of mechanical systems is expressed in terms of the dynamical variables $\mathbf{q} \equiv (q_1, \cdots, q_f)$ and $\dot{\mathbf{q}} \equiv (\dot{q}_1, \cdots, \dot{q}_f)$ with the aid of the Lagrangian $\mathcal{L}(\mathbf{q}, \dot{\mathbf{q}}, t)$ and the Lagrange equations. With this approach we identified the sum over the canonical momenta $\mathbf{p} \equiv (p_1, \cdots, p_f)$ as a conserved quantity of a closed mechanical system. In the Hamilton formalism the dynamical evolution is described in terms of the dynamical variables $\mathbf{q}$ and $\mathbf{p}$; i.e., the dependence on $\dot{\mathbf{q}}$ is eliminated from the formalism and replaced by a dependence on $\mathbf{p}$.

D.6.1 Legendre transformation of Lagrangian - Hamiltonian

To replace the dependence on $\dot{\mathbf{q}}$ by a dependence on $\mathbf{p}$ we use a Legendre transformation of the function $\mathcal{L}(\mathbf{q}, \dot{\mathbf{q}}, t)$ into the function

$$H(\mathbf{q}, \mathbf{p}, t) = \mathbf{p} \cdot \dot{\mathbf{q}} - \mathcal{L}(\mathbf{q}, \dot{\mathbf{q}}, t). \tag{D.117}$$

The function $H(\mathbf{q}, \mathbf{p}, t)$ is called the *function of Hamilton* or *Hamiltonian* of the system. Note that with the sign convention of (D.117) the Hamiltonian represents the energy of the system

$$E = H(\mathbf{q}, \mathbf{p}, t). \tag{D.118}$$

To convince ourselves that the Hamiltonian has the desired properties we consider the total differential

$$dH = -d\mathcal{L} + d(\sum_i p_i \dot{q}_i). \tag{D.119}$$

For the total differential of the Lagrangian $\mathcal{L}(\mathbf{q}, \dot{\mathbf{q}}, t)$ we have with the aid of (D.109a) and (D.109b)

$$d\mathcal{L} = \sum_i \frac{\partial \mathcal{L}}{\partial q_i} dq_i + \sum_i \frac{\partial \mathcal{L}}{\partial \dot{q}_i} d\dot{q}_i + \frac{\partial \mathcal{L}}{\partial t} dt = \sum_i \dot{p}_i dq_i + \sum_i p_i d\dot{q}_i + \frac{\partial \mathcal{L}}{\partial t} dt. \tag{D.120}$$

The total differential of the transformation term is

$$d(\sum_i p_i \dot{q}_i) = \sum_i \dot{q}_i dp_i + \sum_i p_i d\dot{q}_i. \tag{D.121}$$

Substituting (D.120) and (D.121) into (D.119) we obtain

$$dH = -\sum_i \dot{p}_i dq_i + \sum_i \dot{q}_i dp_i + \frac{\partial \mathcal{L}}{\partial t} dt. \tag{D.122}$$

Thus we have verified that H is indeed a function of $\mathbf{q}$ and $\mathbf{p}$. From the total differential we obtain

$$\dot{p}_i = -\frac{\partial H}{\partial q_i} \tag{D.123a}$$

$$\dot{q}_i = +\frac{\partial H}{\partial p_i} \tag{D.123b}$$

with $i \in \{1, \cdots f\}$. These equations are called the *Hamilton equations* of motion. In view of their symmetrical form they are called the *canonical equations* of motion.

D.6.1.1 Energy conservation

From (D.122) we further infer

$$\frac{\partial H}{\partial t} = \frac{\partial \mathcal{L}}{\partial t}. \tag{D.124}$$

Together with (D.118) this shows that the energy is conserved if the Lagrangian (hence, also the Hamiltonian) do not depend explicitly on time; i.e., for $\partial H / \partial t = 0$.

D.6.1.2 Example: charged particle in an electromagnetic field

As an example of a system with a *time-independent* generalized potential function $U(\mathbf{r},\dot{\mathbf{r}})$ we consider the motion of a charged particle in a static electromagnetic field. As we showed in Example D.3.2.3 the force on a charged particle can be written as the gradient of a generalized potential function

$$U(\mathbf{r},\dot{\mathbf{r}}) = q[\varphi(\mathbf{r}) - \mathbf{v}\cdot\mathbf{A}(\mathbf{r})] \tag{D.125}$$

and the Lagrangian is of the form (D.33). As the kinetic energy is given by

$$T(\dot{\mathbf{r}}) = \tfrac{1}{2}m\mathbf{v}^2, \tag{D.126}$$

the Lagrangian becomes

$$\mathcal{L}(\mathbf{r},\dot{\mathbf{r}}) \equiv \tfrac{1}{2}m\mathbf{v}^2 - q[\varphi - \mathbf{v}\cdot\mathbf{A}]. \tag{D.127}$$

From this we calculate the canonical momentum

$$\mathbf{p} \equiv \frac{\partial\mathcal{L}}{\partial\mathbf{v}} = m\mathbf{v} + q\mathbf{A}. \tag{D.128}$$

Thus we found that the canonical momentum consists in this case of two contributions; the first term is called the *kinetic momentum* and the second term the *electromagnetic momentum.* The Hamiltonian is given by

$$H = \mathbf{v}\cdot\mathbf{p} - \mathcal{L} = m\mathbf{v}^2 + q\mathbf{A}\cdot\mathbf{v} - \tfrac{1}{2}m\mathbf{v}^2 + q(\varphi - \mathbf{v}\cdot\mathbf{A}) = \tfrac{1}{2}m\mathbf{v}^2 + q\varphi. \tag{D.129}$$

The potential energy is given by

$$V(\mathbf{r}) = H - T = q\varphi(\mathbf{r}). \tag{D.130}$$

Expressing (D.129) in terms of the canonical variables $\mathbf{r}$ and $\mathbf{p}$ we obtain with the aid of (D.128) the Hamiltonian of the system,

$$H = \frac{1}{2m}(\mathbf{p} - q\mathbf{A})^2 + q\varphi. \tag{D.131}$$

D.7 Center of mass and relative coordinates

D.7.1 Center of mass motion of a closed system

In Section D.5.3 we found that the momentum of a *closed* mechanical system with *velocity-independent* interparticle forces,

$$\mathbf{P} = \sum_\alpha m_\alpha\dot{\mathbf{r}}_\alpha, \tag{D.132}$$

is conserved in time. However, this quantity is not conserved when changing from one inertial frame to another. Obviously, the velocity of the particles depends on the inertial system in which the velocity is measured. Hence, also the kinetic momentum depends on the inertial system. To analyze this dependence we change from the inertial frame $\mathcal{S}$ to a new inertial frame $\mathcal{S}'$ in which the origin of old frame is moving at velocity $\mathbf{V}$. This change of inertial system is described by a *galilean transformation*,

$$\mathbf{r}'_\alpha = \mathbf{r}_\alpha - \mathbf{V}t \tag{D.133a}$$
$$\dot{\mathbf{r}}'_\alpha = \dot{\mathbf{r}}_\alpha - \mathbf{V}. \tag{D.133b}$$

The observed difference in momentum between both inertial systems is given by

$$\mathbf{P}' = \mathbf{P} - \sum_\alpha m_\alpha\mathbf{V}. \tag{D.134}$$

This expression reveals the existence of an inertial frame in which the momentum is zero, $\mathbf{P}' = 0$. Thus we find for the momentum in an inertial system moving with velocity $\mathbf{V}$ with respect to the zero-momentum frame,

$$\mathbf{P} = \sum_\alpha m_\alpha \mathbf{V}. \tag{D.135}$$

In other words, the momentum of the entire system behaves like that of a single particle with mass

$$M = \sum_\alpha m_\alpha. \tag{D.136}$$

This quantity is called the *total mass* of the system. Introducing the position vector

$$\mathbf{R} = \sum_\alpha m_\alpha \mathbf{r}_\alpha / \sum_\alpha m_\alpha \tag{D.137}$$

we find the relation

$$\mathbf{P} = M\dot{\mathbf{R}} = M\mathbf{V}. \tag{D.138}$$

The vector $\mathbf{R}$ is called the *center of mass* of the system. Hence, in the zero-momentum frame the center of mass is at rest.

It is also instructive to compare the total angular momentum in the frame $\mathcal{S}'$ with that in the frame $\mathcal{S}$. Using Eq. (D.133a) the total angular momentum in the frame $\mathcal{S}'$ can be expressed as

$$\mathbf{L}' = \sum_\alpha (\mathbf{r}_\alpha \times \mathbf{p}'_\alpha) - \mathbf{V}t \times \sum_\alpha \mathbf{p}'_\alpha, \tag{D.139}$$

where $\mathbf{V}t$ is the position of the origin of $\mathcal{S}$ as observed in $\mathcal{S}'$. The second term vanishes if we choose for $\mathcal{S}'$ the zero-momentum frame. To proceed we multiply both sides of Eq. (D.133b) by the particles mass,

$$\mathbf{p}'_\alpha = \mathbf{p}_\alpha - m_\alpha \mathbf{V}. \tag{D.140}$$

Substituting this expression into Eq. (D.139) we find

$$\mathbf{L}' = \mathbf{L} - \sum_\alpha (m_\alpha \mathbf{r}_\alpha \times \mathbf{V}). \tag{D.141}$$

In terms of the position and momentum of the center of mass this becomes

$$\mathbf{L} = \mathbf{L}' + \mathbf{R} \times \mathbf{P}. \tag{D.142}$$

Thus we recognize two contributions to the angular momentum of the system: $\mathbf{L}'$ is called the *intrinsic* angular momentum, which is the angular momentum with the center of mass at rest, and $\mathbf{R} \times \mathbf{P}$ is the angular momentum resulting from the center of mass motion in the inertial frame of reference.

D.7.2 Relative motion in a closed system of two atoms

To deal with interatomic interactions and collisions between particles one introduces *relative coordinates*. The position of particle 1 relative to particle 2 is given by

$$\mathbf{r} = \mathbf{r}_1 - \mathbf{r}_2. \tag{D.143}$$

Taking the derivative with respect to time we find for the relative velocity of particle 1 with respect to particle 2

$$\mathbf{v} = \mathbf{v}_1 - \mathbf{v}_2. \tag{D.144}$$

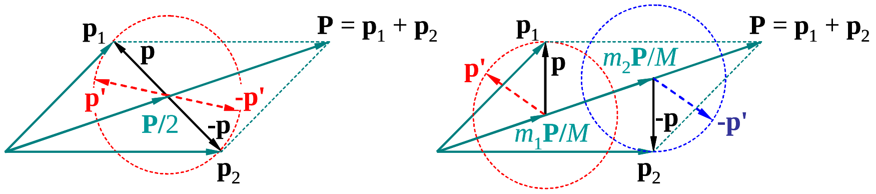

Figure D.1: Center of mass and relative momenta for two colliding atoms: *left*: equal mass; *right*: unequal mass with $m_1/m_2 = 1/3$.

Let us analyze in some detail the case of a system of two particles. The total momentum of the pair (the center of mass momentum) is a conserved quantity and given by

$$\mathbf{P} = \mathbf{p}_1 + \mathbf{p}_2 = m_1\mathbf{v}_1 + m_2\mathbf{v}_2 = m_1\dot{\mathbf{r}}_1 + m_2\dot{\mathbf{r}}_2. \tag{D.145}$$

The total mass is given by the sum of the two particles masses, $M = m_1 + m_2$. With the relation $\mathbf{P} = M\mathbf{V}$, where $\mathbf{V} = \dot{\mathbf{R}}$ is the center of mass velocity, we find for the position of the center of mass

$$\mathbf{R} = (m_1\mathbf{r}_1 + m_2\mathbf{r}_2)/(m_1 + m_2). \tag{D.146}$$

Adding and subtracting (D.145) and (D.144) allows us to express $\mathbf{v}_1$ and $\mathbf{v}_2$ in terms of $\mathbf{P}$ and $\mathbf{v}$,

$$\mathbf{P} + m_2\mathbf{v} = (m_1 + m_2)\,\mathbf{v}_1 \tag{D.147a}$$

$$\mathbf{P} - m_1\mathbf{v} = (m_1 + m_2)\,\mathbf{v}_2. \tag{D.147b}$$

With these expressions the total kinetic energy of the pair, $E = \epsilon_1 + \epsilon_2$, can be split in a contribution of the *center of mass* and a contribution of the relative motion

$$E = \frac{1}{2}m_1\mathbf{v}_1^2 + \frac{1}{2}m_2\mathbf{v}_2^2 = \frac{1}{2}m_1\frac{(\mathbf{P} + m_2\mathbf{v})^2}{(m_1 + m_2)^2} + \frac{1}{2}m_2\frac{(\mathbf{P} - m_1\mathbf{v})^2}{(m_1 + m_2)^2} = \frac{\mathbf{P}^2}{2M} + \frac{\mathbf{p}^2}{2m_r}, \tag{D.148}$$

where

$$\mathbf{p} = m_r\mathbf{v} = m_r\dot{\mathbf{r}} = \frac{m_r}{m_1}\mathbf{p}_1 - \frac{m_r}{m_2}\mathbf{p}_2 \tag{D.149}$$

is the relative momentum with

$$m_r = m_1 m_2/(m_1 + m_2) \tag{D.150}$$

representing the *reduced mass* of the pair. Because both $\mathbf{P}$ and E are conserved quantities in elastic collisions also $\mathbf{p}^2$ must be conserved. This implies that in elastic collisions the relative momentum $p = |\mathbf{p}|$ is conserved, but *not* its direction. Adding and subtracting (D.143) and (D.146) we can express $\mathbf{r}_1$ and $\mathbf{r}_2$ in terms of $\mathbf{R}$ and $\mathbf{r}$,

$$\mathbf{r}_1 = \mathbf{R} + \frac{m_2}{M}\mathbf{r} \text{ and } \mathbf{r}_2 = \mathbf{R} - \frac{m_1}{M}\mathbf{r}. \tag{D.151}$$

Likewise combining (D.145) and (D.149) we can express $\mathbf{p}_1$ and $\mathbf{p}_2$ in terms of $\mathbf{P}$ and $\mathbf{p}$,

$$\mathbf{p}_1 = \frac{m_1}{M}\mathbf{P} + \mathbf{p} \text{ and } \mathbf{p}_2 = \frac{m_2}{M}\mathbf{P} - \mathbf{p}. \tag{D.152}$$

The vector diagram is shown in Fig. D.1.

Problem D.3. Show that the Jacobian of the transformation $d\mathbf{r}_1 d\mathbf{r}_2 = \left|\frac{\partial(\mathbf{r}_1,\mathbf{r}_2)}{\partial(\mathbf{R},\mathbf{r})}\right| d\mathbf{R}d\mathbf{r}$ is -1.

Solution. Because the x, y and z directions separate we can write the Jacobian as the product of three 1D Jacobians.

$$\left|\frac{\partial(\mathbf{r}_1,\mathbf{r}_2)}{\partial(\mathbf{R},\mathbf{r})}\right| = \prod_{i=x,y,z}\left|\frac{\partial(r_{1i},r_{2i})}{\partial(R_i,r_i)}\right| = \prod_{i=x,y,z}\begin{vmatrix} 1 & m_1/M \\ 1 & -m_2/M \end{vmatrix} = -1. \qquad \square$$

Problem D.4. Show that the Jacobian of the transformation $d\mathbf{p}_1 d\mathbf{p}_2 = \left|\frac{\partial(\mathbf{p}_1,\mathbf{p}_2)}{\partial(\mathbf{P},\mathbf{p})}\right| d\mathbf{P}d\mathbf{p}$ is -1.

Solution. Because the x, y and z directions separate we can write the Jacobian as the product of three 1D Jacobians.

$$\left|\frac{\partial(\mathbf{p}_1,\mathbf{p}_2)}{\partial(\mathbf{P},\mathbf{p})}\right| = \prod_{i=x,y,z}\left|\frac{\partial(p_{1i},p_{2i})}{\partial(P_i,p_i)}\right| = \prod_{i=x,y,z}\begin{vmatrix} m_1/M & 1 \\ m_2/M & -1 \end{vmatrix} = -1. \qquad \square$$

D.7.3 Kinematics of scattering

In any collision the momentum $\mathbf{P}$ is conserved. Thus, also the center of mass energy $\mathbf{P}^2/2M$ is conserved and since also the total energy must be conserved also the relative kinetic energy $\mathbf{p}^2/2m_r$ is conserved in *elastic* collisions, be it in general not *during* the collision. In this section we consider the consequence of the conservation laws for the momentum transfer between particles in elastic collisions in which the relative momentum changes from $\mathbf{p}$ to $\mathbf{p}'$, with $\mathbf{q} = \mathbf{p}' - \mathbf{p}$. Because the relative energy is conserved, also the modulus of the relative momentum will be conserved, $|\mathbf{p}| = |\mathbf{p}'|$, and the only effect of the collision is to change the direction of the relative momentum over an angle ϑ. Hence, the *scattering angle* ϑ fully determines the energy and momentum transfer in the collision. Using (D.147) the momenta of the particles before and after the collision (see Fig. D.1) are given by

$$\mathbf{p}_1 = m_1\mathbf{P}/M + \mathbf{p} \longrightarrow \mathbf{p}_1' = m_1\mathbf{P}/M + \mathbf{p}' \qquad \text{(D.153a)}$$

$$\mathbf{p}_2 = m_2\mathbf{P}/M - \mathbf{p} \longrightarrow \mathbf{p}_2' = m_2\mathbf{P}/M - \mathbf{p}'. \qquad \text{(D.153b)}$$

Hence, the momentum transfer is

$$\Delta\mathbf{p}_1 = \mathbf{p}_1' - \mathbf{p}_1 = \mathbf{p}' - \mathbf{p} = \mathbf{q} \qquad \text{(D.154a)}$$

$$\Delta\mathbf{p}_2 = \mathbf{p}_2' - \mathbf{p}_2 = \mathbf{p} - \mathbf{p}' = -\mathbf{q}. \qquad \text{(D.154b)}$$

The energy transfer is

$$\Delta E_1 = \frac{\mathbf{p}_1'^2}{2m_1} - \frac{\mathbf{p}_1^2}{2m_1} = \frac{(m_1\mathbf{P}/M + \mathbf{p}')^2}{2m_1} - \frac{(m_1\mathbf{P}/M + \mathbf{p})^2}{2m_1} = \frac{\mathbf{P}\cdot\mathbf{q}}{M} \qquad \text{(D.155a)}$$

$$\Delta E_2 = \frac{\mathbf{p}_2'^2}{2m_2} - \frac{\mathbf{p}_2^2}{2m_2} = \frac{(m_2\mathbf{P}/M - \mathbf{p}')^2}{2m_2} - \frac{(m_2\mathbf{P}/M - \mathbf{p})^2}{2m_2} = -\frac{\mathbf{P}\cdot\mathbf{q}}{M}. \qquad \text{(D.155b)}$$

In the special case $\mathbf{p}_1 = 0$ we have

$$\mathbf{P} = \mathbf{p}_2 = \frac{-\mathbf{p}}{1 - m_2/M} = -\frac{M}{m_1}\mathbf{p} \qquad \text{(D.156)}$$

or

$$\mathbf{p} = -m_r\mathbf{v}_2. \qquad \text{(D.157)}$$

The momentum transfer becomes

$$q = \sqrt{\mathbf{q}^2} = \sqrt{(\mathbf{p}' - \mathbf{p})^2} = \sqrt{2\mathbf{p}^2 - 2\mathbf{p}'\cdot\mathbf{p}} = p\sqrt{2 - 2\cos\vartheta}. \qquad \text{(D.158)}$$

For small angles this implies

$$\vartheta = q/p. \qquad \text{(D.159)}$$

The energy transfer becomes

$$\Delta E_1 = \frac{\mathbf{P}\cdot\mathbf{q}}{M} = -\frac{\mathbf{p}\cdot(\mathbf{p}' - \mathbf{p})}{m_1} = \frac{\mathbf{p}^2}{m_1}(1 - \cos\vartheta) = \frac{m_r^2}{m_1}\mathbf{v}_2^2(1 - \cos\vartheta), \qquad \text{(D.160)}$$

where ϑ is the scattering angle. This can be written in the form

$$\Delta E_1 = \tfrac{1}{4}\xi m_2 \mathbf{v}_2^2 \left(1-\cos\vartheta\right), \tag{D.161}$$

where

$$\xi = \frac{4m_r^2}{m_1 m_2} = \frac{4m_1 m_2}{\left(m_1+m_2\right)^2} = 4\frac{m_r}{M}. \tag{D.162}$$

is the thermalization efficiency parameter. For $m_1 = m_2$ this parameter reaches its maximum value ($\xi = 1$) and we obtain

$$\Delta E_1 = \tfrac{1}{2} E_2 \left(1-\cos\vartheta\right). \tag{D.163}$$

For $m_1 \ll m_2$ the efficiency parameter is given by $\xi \simeq 4m_1/m_2$.

E

Classical electrodynamics

E.1 Maxwell equations

The central equations of classical electrodynamics are the four equations of Maxwell. In the presence of a free charge density ϱ_e and free current density $\mathbf{J}$ the macroscopic Maxwell equations can be written in the form[1]

$$\boldsymbol{\nabla} \cdot \mathbf{D} = \varrho_e \quad \text{(Gauss)} \tag{E.1a}$$

$$\boldsymbol{\nabla} \times \mathbf{H} - \frac{\partial \mathbf{D}}{\partial t} = \mathbf{J} \quad \text{(Ampère/Maxwell)} \tag{E.1b}$$

$$\boldsymbol{\nabla} \cdot \mathbf{B} = 0 \tag{E.1c}$$

$$\boldsymbol{\nabla} \times \mathbf{E} + \frac{\partial \mathbf{B}}{\partial t} = \mathbf{0} \quad \text{(Faraday).} \tag{E.1d}$$

Here $\mathbf{E}$ is the *electric field strength* and $\mathbf{B}$ is the *magnetic induction.* These are the fields that determine the forces acting on charges and currents, respectively. $\mathbf{H}$ is the *magnetic field strength* and $\mathbf{D}$ the *dielectric displacement.* These fields are important for describing the response of matter. The relation between the two pairs of fields, $\mathbf{B}$ versus $\mathbf{H}$ and $\mathbf{E}$ versus $\mathbf{D}$, is given by the *materials equations*

$$\mathbf{B} = \mu_0(\mathbf{H} + \mathbf{M}) \qquad \mathbf{E} = \varepsilon_0^{-1}(\mathbf{D} - \mathbf{P}), \tag{E.2}$$

where $\mathbf{M}$ is called the *magnetization* and $\mathbf{P}$ the *polarization* of the medium under consideration; $\mu_0 = 4\pi \times 10^{-7}\ \mathrm{N\,A^{-2}}$ and $\varepsilon_0 = 1/\mu_0 c^2 = 8.854187817... \times 10^{-12}\ \mathrm{Fm^{-1}}$ are fundamental constants with defined values, μ_0 is called the *magnetic permeability of vacuum* and ε_0 the *electric permittivity of vacuum.*

E.1.1 Linear media

In *linear media* the magnetization $\mathbf{M}$ (the magnetic moment per unit volume) and polarization $\mathbf{P}$ (the electric dipole moment per unit volume) are given by

$$\mathbf{M} = \chi_m \mathbf{H} \qquad \mathbf{P} = \varepsilon_0 \chi_e \mathbf{E}, \tag{E.3}$$

where χ_m is the *magnetic susceptibility* and χ_e the *electric susceptibility* of the material. Dividing the susceptibilities by the atomic density N/V one obtains (for dilute systems) the magnetic and electric *polarizabilities* α_M and α_E,

$$\chi_m = \mu_0\,(N/V)\,\alpha_M \tag{E.4a}$$

$$\chi_e = (N/V)\,\alpha_E. \tag{E.4b}$$

---

[1] See for instance: J.D. Jackson, *Classical electrodynamics*, John Wiley & Sons, 3rd edition, New York 1998.

Substituting these expressions into the materials equations they become

$$\mathbf{B} = \mu_0(1+\chi_m)\mathbf{H} = \mu\mathbf{H} \tag{E.5a}$$

$$\mathbf{D} = \varepsilon_0(1+\chi_e)\mathbf{E} = \varepsilon\mathbf{E}, \tag{E.5b}$$

where $\mu = \mu_0(1+\chi_m) = \mu_0\mu_{rel}$ is the *permeability* and $\varepsilon = \varepsilon_0(1+\chi_m) = \varepsilon_0\varepsilon_{rel}$ the *permittivity* of the material. In these media the **D** and **H** fields can be eliminated and the Maxwell equations can be written in the form

$$\boldsymbol{\nabla}\cdot\mathbf{E} = \varrho_e/\varepsilon \quad \text{(Gauss)} \tag{E.6a}$$

$$\boldsymbol{\nabla}\times\mathbf{B} - \frac{\partial\mathbf{E}}{c^2\partial t} = \mu\mathbf{J} \quad \text{(Ampère/Maxwell)} \tag{E.6b}$$

$$\boldsymbol{\nabla}\cdot\mathbf{B} = 0 \tag{E.6c}$$

$$\boldsymbol{\nabla}\times\mathbf{E} + \frac{\partial\mathbf{B}}{\partial t} = 0 \quad \text{(Faraday),} \tag{E.6d}$$

where $c = (\mu\varepsilon)^{-1/2}$ is the speed of light in the medium. Combining equations we obtain, with the aid of Eq. (N.24), for the **E** and **B** fields separately

$$-\boldsymbol{\nabla}^2\mathbf{B} + \frac{\partial^2\mathbf{B}}{c^2\partial t^2} = \mu\boldsymbol{\nabla}\times\mathbf{J} \tag{E.7}$$

$$-\boldsymbol{\nabla}^2\mathbf{E} + \frac{\partial^2\mathbf{E}}{c^2\partial t^2} = -\mu\mathbf{J} - \frac{1}{\varepsilon}\boldsymbol{\nabla}\varrho_e. \tag{E.8}$$

In vacuum $\mu_{rel} = 1$ and $\varepsilon_{rel} = 1$ and $c = (\mu_0\varepsilon_0)^{-1/2}$ and including all charges and currents (also those inside atoms) the Maxwell equations are referred to as the *microscopic Maxwell equations* or *Maxwell-Lorentz equations.*

E.1.2 Scalar and vector potentials and gauge freedom

Using the vector identity (N.23) and the Maxwell equation (E.6c) the **B** field can be derived from a vector potential **A** by requiring

$$\mathbf{B} = \boldsymbol{\nabla}\times\mathbf{A}. \tag{E.9}$$

Substituting this expression into the Maxwell equation (E.6d) we obtain

$$\boldsymbol{\nabla}\times(\mathbf{E} + \partial\mathbf{A}/\partial t) = 0. \tag{E.10}$$

Thus, in view of the vector identity (N.22) we infer that the **E** field can be derived from the equation

$$\mathbf{E} = -\boldsymbol{\nabla}\varphi - \partial\mathbf{A}/\partial t. \tag{E.11}$$

In view of the Helmholtz theorem (N.5) the vector potential **A** can be separated in a *solenoidal* or *divergence-free* part, $\mathbf{A}_\perp$, and a *irrotational* or *rotation-free* part, $\mathbf{A}_\|$,

$$\mathbf{A} = \mathbf{A}_\perp + \mathbf{A}_\| \text{ with } \boldsymbol{\nabla}\cdot\mathbf{A}_\perp = 0 \text{ and } \boldsymbol{\nabla}\times\mathbf{A}_\| = 0. \tag{E.12}$$

The potentials **A** and φ are not uniquely defined. Eq. (E.9) remains satisfied under the transformation $\mathbf{A}' \to \mathbf{A} = \mathbf{A}' + \boldsymbol{\nabla}\chi$, where $\chi(\mathbf{r},t)$ is an arbitrary scalar field because $\boldsymbol{\nabla}\times\boldsymbol{\nabla}\chi = 0$ for all scalar fields χ. Furthermore, under the simultaneous transformation $\varphi = \varphi' - \partial\chi/\partial t$ also Eq. (E.11) remains satisfied. This is known as *gauge freedom.* The transformation $(\mathbf{A}',\varphi') \to (\mathbf{A},\varphi)$ is called a *gauge transformation* and the field $\chi(\mathbf{r},t)$ the *gauge field.* The invariance of Eqs. (E.9) and (E.11) under gauge transformations is called *gauge invariance.* Also the fields **B** and **E** are *gauge invariant.* In view of the Helmholtz theorem (E.12), the gauge invariance of Eq. (E.9) always allows us to freely choose $\mathbf{A}_\|$.

For the electromagnetic field we mention two important gauges:

- In the *Coulomb gauge* the gauge freedom is used to make the vector potential *divergence-free*,

  $$\boldsymbol{\nabla}\cdot\mathbf{A}=\boldsymbol{\nabla}\cdot(\mathbf{A}'+\boldsymbol{\nabla}\chi)=0. \tag{E.13}$$

  This condition is satisfied if the gauge field satisfies the relation $\boldsymbol{\nabla}^2\chi=-\boldsymbol{\nabla}\cdot\mathbf{A}'$. This gauge implies $\mathbf{A}_{\|}=0$ as follows by using the Helmholtz relation $\boldsymbol{\nabla}\cdot\mathbf{A}_{\perp}=0$. In this sense the vector potential can be called *transverse*. More precisely, by spatial Fourier transformation

  $$\mathbf{A}(\mathbf{r},t)=\frac{1}{(2\pi)^{3/2}}\int\vec{\mathcal{A}}(\mathbf{k},t)e^{i\mathbf{k}\cdot\mathbf{r}}d\mathbf{k} \tag{E.14}$$

  the Eq. (E.13) turns into

  $$\mathbf{k}\cdot\vec{\mathcal{A}}(\mathbf{k},t)=0. \tag{E.15}$$

  Hence, the Fourier components of the vector potential are transverse with respect to the vector $\mathbf{k}$ in reciprocal space.

- In the *Lorenz gauge* the gauge freedom is used to satisfy the Lorenz condition,

  $$\begin{aligned}\boldsymbol{\nabla}\cdot\mathbf{A}+\frac{1}{c^2}\frac{\partial\varphi}{\partial t}&=\boldsymbol{\nabla}\cdot(\mathbf{A}'+\boldsymbol{\nabla}\chi)+\frac{1}{c^2}\frac{\partial}{\partial t}(\varphi'-\partial\chi/\partial t)\\&=\boldsymbol{\nabla}\cdot\mathbf{A}'+\boldsymbol{\nabla}^2\chi+\frac{1}{c^2}\frac{\partial\varphi'}{\partial t}-\frac{1}{c^2}\frac{\partial^2\chi}{\partial t^2}=0.\end{aligned}$$

  This condition is satisfied if the gauge field satisfies the relation $\boldsymbol{\nabla}^2\chi=-\boldsymbol{\nabla}\cdot\mathbf{A}'-c^{-2}\partial\varphi/\partial t+c^{-2}\partial^2\chi/\partial^2 t$.

E.2 Transformation formulas for moving objects

An observer moving in an static electromagnetic field experiences a *velocity-induced* electromagnetic field given by

$$\begin{array}{ll}\mathbf{E}'_{\perp}=\gamma\left(\mathbf{E}_{\perp}+\mathbf{v}\times\mathbf{B}_{\perp}\right) & \mathbf{B}'_{\perp}=\gamma\left(\mathbf{B}_{\perp}-\dfrac{\mathbf{v}}{c^2}\times\mathbf{E}_{\perp}\right)\\ \mathbf{E}'_{\|}=\mathbf{E}_{\|} & \mathbf{B}'_{\|}=\mathbf{B}_{\|},\end{array} \tag{E.16}$$

where $\gamma=(1-v^2/c^2)^{-1/2}$ is the *Lorentz contraction factor*. For an observer moving at a non-relativistic velocity in a static magnetic field $\mathbf{B}$ this reduces to

$$\begin{array}{ll}\mathbf{E}'_{\perp}\simeq\mathbf{v}\times\mathbf{B}_{\perp} & \mathbf{B}'_{\perp}\simeq\mathbf{B}_{\perp}\\ \mathbf{E}'_{\|}=0 & \mathbf{B}'_{\|}=\mathbf{B}_{\|}.\end{array} \tag{E.17}$$

Likewise, for an observer moving at a non-relativistic velocity in a static electric field $\mathbf{E}$ we have

$$\begin{array}{ll}\mathbf{B}'_{\perp}\simeq-\dfrac{\mathbf{v}}{c^2}\times\mathbf{E}_{\perp} & \mathbf{E}'_{\perp}\simeq\mathbf{E}_{\perp}\\ \mathbf{B}'_{\|}=0 & \mathbf{E}'_{\|}=\mathbf{E}_{\|}.\end{array} \tag{E.18}$$

For an observer moving orthogonal to the direction of a static electric or magnetic field this is illustrated in Fig. E.1.

E.3 Current-charge distributions in the quasi-static approximation

E.3.1 Introduction

Let us consider a *current-charge distribution* in vacuum, localized at the origin of a coordinate system as illustrated in Fig. E.1. The current-charge distribution is defined by the *charge-density distribution* $\varrho_e(\mathbf{r},t)$ and the *current-density distribution* $\mathbf{J}(\mathbf{r},t)$, which are coupled through the *continuity*

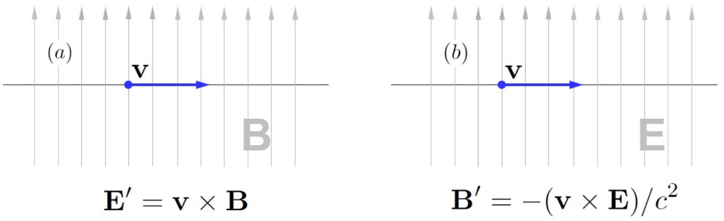

Figure E.1: (*a*) An observer moving perpendicularly to the direction of a static magnetic field experiences a velocity-induced electric field; (*b*) an observer moving orthogonal to the direction of a static electric field experiences a velocity-induced magnetic field. The formulas are valid in the weakly-relativistic limit ($v \ll c$).

equation

$$\frac{\partial \varrho_e}{\partial t} + \boldsymbol{\nabla} \cdot \mathbf{J} = 0. \tag{E.19}$$

The charge-density distribution is normalized on the total free charge q of the system under consideration,

$$\int \varrho_e(\mathbf{r}, t) d\mathbf{r} = q. \tag{E.20}$$

Rather than using charge densities and current densities we give preference to work with neutral densities n and neutral currents $\mathbf{j}$,

$$\varrho_e(\mathbf{r}, t) = q\, n(\mathbf{r}, t) \tag{E.21a}$$

$$\mathbf{J}(\mathbf{r}, t) = q\, \mathbf{j}(\mathbf{r}, t), \tag{E.21b}$$

where

$$\int n(\mathbf{r}, t) d\mathbf{r} = 1. \tag{E.22}$$

Under quasi-static conditions (no retardation), the electromagnetic potentials of this current-charge distribution are given by

$$\varphi(\mathbf{r}, t) = \frac{q}{4\pi\varepsilon_0} \int \frac{1}{|\mathbf{r} - \mathbf{r}'|} n(\mathbf{r}', t) d\mathbf{r}' \tag{E.23a}$$

$$\mathbf{A}(\mathbf{r}, t) = \frac{\mu_0}{4\pi} q \int \frac{1}{|\mathbf{r} - \mathbf{r}'|} \mathbf{j}(\mathbf{r}', t) \cdot d\mathbf{r}'. \tag{E.23b}$$

Note that by using for $n(\mathbf{r}, t)$ a delta-function distribution centered at the origin Eq. (E.23a) reduces to the well-known expression for the *Coulomb potential* of an electric point charge q,

$$\varphi(\mathbf{r}, t) = \int \frac{q\delta^3(\mathbf{r}', t)}{4\pi\varepsilon_0 |\mathbf{r} - \mathbf{r}'|} d\mathbf{r}' = \frac{q}{4\pi\varepsilon_0 |\mathbf{r}|}. \tag{E.24}$$

Hence, the integrand of Eq. (E.23a) represents the contribution of a point-charge density at position $\mathbf{r}'$ to the scalar potential. Likewise, the integrand of Eq. (E.23a) represents the contribution of the current density at position $\mathbf{r}'$ to the vector potential.

For a point $\mathbf{r}$ far from the current-charge distribution we can expand $1/|\mathbf{r} - \mathbf{r}'|$ in terms of a Taylor series in $\mathbf{r}'$ about the origin. For $r'/r < 1$ the expansion is given by,

$$\frac{1}{|\mathbf{r} - \mathbf{r}'|} = \sum_{n=0}^{\infty} \frac{1}{n!} (\mathbf{r}' \cdot \boldsymbol{\nabla}')^n \left. \frac{1}{|\mathbf{r} - \mathbf{r}'|} \right|_{\mathbf{r}'=0}. \tag{E.25}$$

Since $\boldsymbol{\nabla}'|\mathbf{r}-\mathbf{r}'| = -\boldsymbol{\nabla}|\mathbf{r}-\mathbf{r}'|$ (as is easily verified in cartesian coordinates) the Taylor series can be written in the form

$$\frac{1}{|\mathbf{r}-\mathbf{r}'|} = \sum_{n=0}^{\infty} \frac{(-1)^n}{n!}(\mathbf{r}'\cdot\boldsymbol{\nabla})^n \frac{1}{|\mathbf{r}|}. \tag{E.26}$$

The function $1/|\mathbf{r}-\mathbf{r}'|$ is called a generating function for the Legendre polynomials because the expansion can be written in the form

$$\frac{1}{|\mathbf{r}-\mathbf{r}'|} = \frac{1}{r}\sum_l \left(\frac{r'}{r}\right)^l P_l(\cos\theta) \quad \text{for } r'/r<1, \tag{E.27}$$

where $r = |\mathbf{r}|$ and $u = \hat{\mathbf{r}}\cdot\hat{\mathbf{r}}' = \cos\theta$, with θ the angle included by the unit vectors $\hat{\mathbf{r}}$ and $\hat{\mathbf{r}}'$. This is readily verified order for order,

- *zero* order

$$\frac{1}{r}P_0(\cos\theta) = \frac{1}{r}, \tag{E.28}$$

- in *first* order we obtain with the aid of Eq. (N.18)

$$\frac{r'}{r^2}P_1(\cos\theta) = -(\mathbf{r}'\cdot\boldsymbol{\nabla})\frac{1}{r} = \frac{1}{r^3}(\mathbf{r}'\cdot\mathbf{r}) = \frac{r'}{r^2}\cos\theta, \tag{E.29}$$

- in *second* order we obtain with the aid of Eq. (N.18)

$$\begin{aligned}
\frac{r'^2}{r^3}P_2(\cos\theta) &= \frac{1}{2}(\mathbf{r}'\cdot\boldsymbol{\nabla})(\mathbf{r}'\cdot\boldsymbol{\nabla})\frac{1}{r}\\
&= -\frac{1}{2}(\mathbf{r}'\cdot\boldsymbol{\nabla})\frac{1}{r^3}(\mathbf{r}'\cdot\mathbf{r})\\
&= -\frac{1}{2}\left[(\mathbf{r}'\cdot\mathbf{r})(\mathbf{r}'\cdot\boldsymbol{\nabla})\frac{1}{r^3} + \frac{1}{r^3}(\mathbf{r}'\cdot\boldsymbol{\nabla})(\mathbf{r}'\cdot\mathbf{r})\right]\\
&= \frac{1}{2}\left[\frac{3}{r^5}(\mathbf{r}'\cdot\mathbf{r})(\mathbf{r}'\cdot\mathbf{r}) - \frac{1}{r^3}(\mathbf{r}'\cdot\mathbf{r}')\right]\\
&= \frac{r'^2}{r^3}\tfrac{1}{2}\left[3\cos^2\theta - 1\right].
\end{aligned} \tag{E.30}$$

E.3.2 Expansion of the scalar potential

Substituting Eq. (E.27) into Eq. (E.23a) we obtain for the scalar potential

$$\varphi(\mathbf{r},t) = \frac{q}{4\pi\varepsilon_0 r}\sum_l \int \left(\frac{r'}{r}\right)^l P_l(\cos\theta) n(\mathbf{r}',t)d\mathbf{r}' \quad \text{for } r'/r<1. \tag{E.31}$$

Limiting the expansion to power $n=2$,

$$\varphi(\mathbf{r},t) = \frac{q}{4\pi\varepsilon_0 r}\int\left[1 + P_1(\cos\theta)\frac{r'}{r} + P_2(\cos\theta)\left(\frac{r'}{r}\right)^2 + \cdots\right] n(\mathbf{r}',t)d\mathbf{r}'. \tag{E.32}$$

Evaluating these terms order for order we obtain:

- *zero* order

$$\varphi^{(0)}(\mathbf{r},t) = \frac{q}{4\pi\varepsilon_0 r}\int n(\mathbf{r}',t)d\mathbf{r}' = \frac{q}{4\pi\varepsilon_0 r}, \tag{E.33}$$

- *first* order

$$\varphi^{(1)}(\mathbf{r},t) = \frac{q}{4\pi\varepsilon_0 r^2}\int P_1(\cos\theta)r'n(\mathbf{r}',t)d\mathbf{r}' = \frac{q}{4\pi\varepsilon_0}\frac{\mathbf{d}\cdot\mathbf{r}}{r^3}, \tag{E.34}$$

where the dipole moment of the charge distribution is defined as

$$\mathbf{d} = q\int \mathbf{r}'n(\mathbf{r}',t)d\mathbf{r}'. \tag{E.35}$$

- *second* order

$$\begin{aligned}\varphi^{(2)}(\mathbf{r},t) &= \frac{q}{4\pi\varepsilon_0 r^3}\int P_2(\cos\theta)r'^2 n(\mathbf{r}',t)d\mathbf{r}' \\ &= \frac{q}{4\pi\varepsilon_0}\frac{1}{r^3}\int \tfrac{1}{2}\left[3(\mathbf{r}'\cdot\hat{\mathbf{r}})^2 - r'^2\right]n(\mathbf{r}',t)d\mathbf{r}' \\ &= \frac{q}{4\pi\varepsilon_0}\frac{1}{2r^5}\int \left[3(\textstyle\sum_i x_i'x_i)(\sum_j x_j'x_j) - r'^2\right]n(\mathbf{r}',t)d\mathbf{r}' \\ &= \frac{q}{4\pi\varepsilon_0}\frac{1}{2}\sum_{i,j}Q_{ij}\frac{x_ix_j}{r^5},\end{aligned} \tag{E.36}$$

where x_i are the cartesian components of $\mathbf{r}$ and Q_{ij} the components of the quadrupole moment tensor

$$Q_{ij} = \int \left[3x_i'x_j' - r'^2\delta_{ij}\right]n(\mathbf{r}',t)d\mathbf{r}'. \tag{E.37}$$

E.3.3 Expansion of the Vector potential

Substituting Eq. (E.27) into Eq. (E.23b) we obtain for the vector potential

$$\mathbf{A}(\mathbf{r},t) = \frac{\mu_0}{4\pi r}q\sum_l\left(\frac{r'}{r}\right)^l P_l(\cos\theta)\mathbf{j}(\mathbf{r}',t)d\mathbf{r}' \quad \text{for } r'/r < 1. \tag{E.38}$$

Limiting the expansion to power $n = 2$,

$$\mathbf{A}(\mathbf{r},t) = \frac{\mu_0}{4\pi r}q\int \mathbf{j}(\mathbf{r}',t)d\mathbf{r}' + \frac{\mu_0}{4\pi r^2}q\int P_1(\cos\theta)r'\mathbf{j}(\mathbf{r}',t)d\mathbf{r}' + \frac{\mu_0}{4\pi r^3}\int P_2(\cos\theta)r'^2\mathbf{j}(\mathbf{r}',t)d\mathbf{r}' + \cdots. \tag{E.39}$$

Let us write the current density of a moving point charge in the form

$$\mathbf{j}(\mathbf{r}') = q\,\dot{\mathbf{r}}'\delta(\mathbf{r}') \tag{E.40}$$

and evaluate the terms of the expansion order for order we obtain:

- zero order

$$\mathbf{A}^{(0)}(\mathbf{r},t) = \frac{\mu_0}{4\pi}\frac{q}{r}\int \dot{\mathbf{r}}'\delta(\mathbf{r}')d\mathbf{r}' = \frac{\mu_0}{4\pi r}q\frac{\mathbf{v}}{r} \tag{E.41}$$

- first order

$$\mathbf{A}^{(1)}(\mathbf{r},t) = \frac{\mu_0}{4\pi}\frac{q}{r^2}\int P_1(\cos\theta)r'\dot{\mathbf{r}}'\delta(\mathbf{r}')d\mathbf{r}' \tag{E.42}$$

- second order

$$\begin{aligned}\mathbf{A}^{(2)}(\mathbf{r},t) &= \frac{\mu_0}{4\pi}\frac{q}{r^3}\int P_2(\cos\theta)r'^2\mathbf{j}(\mathbf{r}',t)d\mathbf{r}' \\ &= \frac{\mu_0}{4\pi}\frac{q}{2r^3}\int \left[3(\mathbf{r}'\cdot\hat{\mathbf{r}})^2 - \mathbf{r}'\cdot\mathbf{r}'\right]\mathbf{j}(\mathbf{r}',t)d\mathbf{r}' \\ &= \frac{\mu_0}{4\pi}\frac{q}{2r^5}\int \left[3(\textstyle\sum_i x_i'x_i)(\sum_j x_j'x_j) - r'^2\right]\dot{\mathbf{r}}'\delta(\mathbf{r}')d\mathbf{r}'.\end{aligned} \tag{E.43}$$

F

Various concepts from Quantum Mechanics

In this appendix we give a summary of formal quantum mechanics for purposes of internal reference. For a proper introduction the reader is referred to one of the major textbooks on quantum mechanics, such as those by Paul Dirac [34], Albert Messiah [75, 76], Gordon Baym [10], Claude Cohen-Tannoudji, Bernard Diu and Franck Laloë [26], Eugen Merzbacher [74], and Jun John Sakurai [96].

F.1 Dirac formalism

F.1.1 Introduction

In the formulation of Dirac, the dynamical state of a physical system is established by observation of its *dynamical variables* (e.g., the position of a particle, its translational momentum, orbital angular momentum with respect to a point of reference, spin, energy, ...). Each dynamical variable $\mathcal{A}$ corresponds to a *hermitian operator* A which defines a *complete orthonormal set of eigenstates* $\{|a_i\rangle\}$ called *kets*, representing the *basis vectors* of a complex vector space, the *Hilbert space* of the dynamical system. A hermitian operator with the mentioned properties is called an *observable*. The set of eigenstates $\{|a_i\rangle\}$ is called a *representation* of the Hilbert space, often referred to as the representation $\{A\}$. The representation $\{A\}$ serves to describe measurements of the observable A. The measurement is expressed by the eigenvalue relation

$$A|a_i\rangle = a_i|a_i\rangle, \tag{F.1}$$

where a_i is the eigenvalue corresponding to the eigenstate $|a_i\rangle$. Observables are characterized by a spectrum of *real* eigenvalues. The kets are abstract state vectors which provide a *representation-free notation* for the *states*. In this introduction we focus on *discrete* representations (e.g., the standard representation $\{L^2, L_z\}$ of orbital angular momentum - cf. Appendix F.1.3). The discussion can be extended to *continuous* representations in which summations are replaced by integrations and in the orthonormality condition the Kronecker symbol becomes a Dirac delta function - cf. Appendix F.1.2.

By *completeness* we mean that an arbitrary state $|\psi\rangle$ of the system can be *represented* by the linear superposition,

$$|\psi\rangle = \sum_i |a_i\rangle\langle a_i|\psi\rangle, \tag{F.2}$$

where $\langle a_i|\psi\rangle$ is the *inner product* of the vectors $|\psi\rangle$ and $|a_i\rangle$; i.e., the *projection* of $|\psi\rangle$ onto $|a_i\rangle$. This is called the *superposition principle.* In matrix notation $\langle a_i|$ is written as a row vector and $|\psi\rangle$ as a column vector. In the Dirac formalism, the vectors $\langle a_i|$ are called *bras*. They are related to the *kets* by hermitian conjugation (antilinear transposition - in matrix notation the column vector is transformed into a row vector with the coordinates replaced by their complex conjugates;

i.e., $\langle\phi|\psi\rangle^* = \langle\psi|\phi\rangle$). The *orthonormality* of the basis is expressed by the property $\langle a_j|a_i\rangle = \delta_{ij}$. The inner product $\langle a_i|\psi\rangle$ represents the *amplitude*, short for *probability amplitude*, to observe the eigenstate $|a_i\rangle$ when the system prepared in the state $|\psi\rangle$. The corresponding *density*, short for *probability density* or *occupation density*, is given by

$$\mathcal{P}_i = |\langle a_i|\psi\rangle|^2. \tag{F.3}$$

The completeness of the representation $\{A\}$ is expressed by the *Parseval relation* (which is a probability sum rule),

$$\sum_i \mathcal{P}_i = \sum_i |\langle a_i|\psi\rangle|^2 = 1 \tag{F.4}$$

and the *closure relation* (which is a decomposition sum rule),

$$\mathbb{1} = \sum_i |a_i\rangle\langle a_i|. \tag{F.5}$$

Here $\mathbb{1}$ is the *identity operator.*

Presuming $|\psi\rangle$ to be normalized, $\langle\psi|\psi\rangle = 1$, the quantity

$$\langle A\rangle = \langle\psi|A|\psi\rangle \tag{F.6}$$

is called the *expectation value* of the operator A. For $|\phi\rangle = A|\psi\rangle$ we write $\langle\psi|A^\dagger = \langle\phi|$, where $A^\dagger$ is called the hermitian conjugate of A. This implies the relation

$$\langle\psi|A|\psi\rangle^* = \langle\psi|A^\dagger|\psi\rangle, \tag{F.7}$$

which is real for hermitian operators ($A^\dagger = A$). If the matrix elements $\langle b_i|A|b_j\rangle$ of the operator A are known in some representation $\{B\}$, the expectation value is given by

$$\langle A\rangle = \sum_{i,j}\langle\psi|b_j\rangle\langle b_j|A|b_i\rangle\langle b_i|\psi\rangle. \tag{F.8}$$

For the representation $\{A\}$, defined above, the matrix is diagonal, $\langle a_i|A|a_j\rangle = a_i\delta_{i,j}$, and Eq. (F.8) reduces to

$$\langle A\rangle = \sum_i\langle\psi|a_i\rangle a_i\langle a_i|\psi\rangle = \sum_i a_i\mathcal{P}_i. \tag{F.9}$$

This result is also intuitively correct: the expectation value corresponds to the sum of the eigenvalues weighted by the probability to have that eigenvalue.

Two dynamical variables $\mathcal{A}$ and $\mathcal{B}$ are called *compatible* if they can be measured simultaneously to arbitrary precision; i.e., share a complete set of eigenstates. This is the case if and only if the corresponding operators A and B commute. Operators that do not commute are called *incompatible.* In general, the shared basis is not uniquely defined, because two eigenstates can have the same eigenvalues. This is called *degeneracy.* To obtain a unique basis a *complete set of commuting observables* $A, B, C, \cdots$ is required, together providing all quantum numbers of the dynamical system. This is called the representation $\{A, B, C, \cdots\}$.

Problem F.1. Show that two commuting observables A and B share a complete set of eigenstates.

Solution. Consider the eigenvalue equations for the operators A and B,

$$A\,|\alpha,k\rangle = \alpha\,|\alpha,k\rangle \;\text{ and }\; B\,|\beta,l\rangle = \beta\,|\beta,l\rangle\,,$$

where $\{|\alpha,k\rangle\}$ is a complete set of k_α-fold degenerate states corresponding to the operator A and $\{|\beta,l\rangle\}$ a complete set of l_β-fold degenerate states corresponding to the operator B. In search for a joint basis we know that the eigenstates of A can be expressed in the eigenstates of B

$$|\alpha,k\rangle = \sum_\beta\sum_{l=1}^{l_\beta}|\beta,l\rangle\,\langle\beta,l|\alpha,k\rangle = \sum_\beta|\beta\rangle\,,$$

where

$$|\beta\rangle \equiv \sum_{l=1}^{l_\beta} |\beta, l\rangle \langle \beta, l|\alpha, k\rangle \,.$$

Note that $|\beta\rangle$ is a linear combination of *degenerate* eigenstates of B, all with eigenvalue β. This implies that $|\beta\rangle$ itself is an eigenstate of B with eigenvalue β as follows from

$$B\,|\beta\rangle \equiv \sum_{l=1}^{l_\beta} B\,|\beta, l\rangle \langle \beta, l|\alpha, k\rangle = \sum_{l=1}^{l_\beta} \beta\,|\beta, l\rangle \langle \beta, l|\alpha, k\rangle = \beta\,|\beta\rangle \,.$$

Next we show that $|\beta\rangle$ is also an eigenstate of A. Since $[A, B] = 0$ we have

$$B(A\,|\beta\rangle) = AB\,|\beta\rangle = A\beta\,|\beta\rangle = \beta(A\,|\beta\rangle).$$

Hence $A\,|\beta\rangle$ is also an eigenstate of B with eigenvalue β. Having the eigenvalue β this eigenstate has to be of the form, $A\,|\beta\rangle = \lambda\,|\beta\rangle$. This shows that $|\beta\rangle$ is also an eigenstate of A. The corresponding eigenvalue λ has to be equal to α as follows from

$$\sum_\beta A\,|\beta\rangle = A\,|\alpha, k\rangle = \alpha\,|\alpha, k\rangle = \sum_\beta \alpha\,|\beta\rangle \,. \qquad \square$$

F.1.2 Continuous bases - position and momentum representation

For a particle in the *arbitrary* state $|\psi\rangle$ the wavefunction $\psi(\mathbf{r})$ represents the probability amplitude to observe the particle at position $\mathbf{r}$. The $\psi(\mathbf{r})$ defines the state $|\psi\rangle$ in the *position representation* and $\mathbf{r}$ stands for the *position coordinates.* In the Dirac formalism the same probability amplitude is obtained by projecting the state vector $|\psi\rangle$ onto the eigenstate $|\mathbf{r}\rangle$ of the position operator $\underline{\mathbf{r}}$,

$$\psi(\mathbf{r}) = \langle \mathbf{r}|\psi\rangle. \tag{F.10}$$

The set $\{|\mathbf{r}\rangle\}$ forms a basis of the Hilbert space of the particle because $|\psi\rangle$ is completely defined by specifying the probability amplitude $\psi(\mathbf{r})$ for all values of $\mathbf{r}$,

$$|\psi\rangle = \int d\mathbf{r}\, |\mathbf{r}\rangle\langle \mathbf{r}|\psi\rangle. \tag{F.11}$$

This shows that the closure relation is given by

$$\mathbb{1} = \int d\mathbf{r}\, |\mathbf{r}\rangle\langle \mathbf{r}| \tag{F.12}$$

and the Parseval relation takes the form of the normalization integral,

$$1 = \int d\mathbf{r} |\langle \mathbf{r}|\psi\rangle|^2 = \int |\psi(\mathbf{r})|^2 d\mathbf{r}. \tag{F.13}$$

To find the orthogonality relation for the position representation we note that the probability amplitude to observe the particle at position $\mathbf{r}'$ is given by

$$\psi(\mathbf{r}') = \int d\mathbf{r}\, \langle \mathbf{r}'|\mathbf{r}\rangle \psi(\mathbf{r}). \tag{F.14}$$

Since $|\psi\rangle$ was chosen arbitrary this implies

$$\langle \mathbf{r}'|\mathbf{r}\rangle = \delta(\mathbf{r} - \mathbf{r}'), \tag{F.15}$$

which is the Dirac deltafunction in three dimensions.

In search for the *momentum representation* we consider the Fourier transform

$$\psi(\mathbf{p}) = \int d\mathbf{r}\, e^{-i\mathbf{p}\cdot\mathbf{r}/\hbar}\psi(\mathbf{r}). \tag{F.16}$$

The inverse transform is given by

$$\psi(\mathbf{r}) = (2\pi\hbar)^{-3}\int d\mathbf{p}\, e^{i\mathbf{p}\cdot\mathbf{r}/\hbar}\psi(\mathbf{p}). \tag{F.17}$$

In the plane wave $e^{i\mathbf{p}\cdot\mathbf{r}/\hbar}$ we recognize the wavefunction of a free particle in state $|\mathbf{p}\rangle$,

$$\langle\mathbf{r}|\mathbf{p}\rangle = e^{i\mathbf{p}\cdot\mathbf{r}/\hbar}. \tag{F.18}$$

Substituting this expression into the Fourier transform (F.16) we find with the aid of the closure relation (F.12)

$$\psi(\mathbf{p}) = \int d\mathbf{r}\,\langle\mathbf{p}|\mathbf{r}\rangle\langle\mathbf{r}|\psi\rangle = \langle\mathbf{p}|\psi\rangle. \tag{F.19}$$

Substituting this expression into the inverse transform we obtain

$$|\psi\rangle = (2\pi\hbar)^{-3}\int d\mathbf{p}\,|\mathbf{p}\rangle\langle\mathbf{p}|\psi\rangle. \tag{F.20}$$

Since $|\psi\rangle$ was chosen arbitrarily, this shows that the set $\{|\mathbf{p}\rangle\}$ forms the basis of the momentum representation for the Hilbert of the particle. The wavefunction $\psi(\mathbf{p}) = \langle\mathbf{p}|\psi\rangle$ represents the probability amplitude that the particle is measured with momentum $\mathbf{p}$. The closure relation is given by

$$\mathbb{1} = (2\pi\hbar)^{-3}\int d\mathbf{p}\,|\mathbf{p}\rangle\langle\mathbf{p}| \tag{F.21}$$

and the Parseval relation becomes,

$$1 = (2\pi\hbar)^{-3}\int d\mathbf{p}|\langle\mathbf{p}|\psi\rangle|^2 = (2\pi\hbar)^{-3}\int |\psi(\mathbf{p})|^2 d\mathbf{p}. \tag{F.22}$$

To find the orthogonality relation we note that the probability amplitude to find the particle with momentum $\mathbf{p}'$ is given by

$$\psi(\mathbf{p}') = (2\pi\hbar)^{-3}\int d\mathbf{p}\,\langle\mathbf{p}'|\mathbf{p}\rangle\psi(\mathbf{p}). \tag{F.23}$$

Since $|\psi\rangle$ was chosen arbitrary we obtain

$$\langle\mathbf{p}'|\mathbf{p}\rangle = (2\pi\hbar)^3\delta(\mathbf{p}-\mathbf{p}'). \tag{F.24}$$

Using the closure relation (F.12) as well as Eq. (F.18) we find the expression

$$\int d\mathbf{r}\langle\mathbf{p}'|\mathbf{r}\rangle\langle\mathbf{r}|\mathbf{p}\rangle = \int d\mathbf{r}\, e^{i(\mathbf{p}-\mathbf{p}')\cdot\mathbf{r}/\hbar} = (2\pi\hbar)^3\delta(\mathbf{p}-\mathbf{p}'). \tag{F.25}$$

F.1.3 Discrete basis - orbital angular momentum

As an example of a discrete basis, we discuss the case of orbital angular momentum. The three cartesian components of the angular momentum operator $\mathbf{L}$ satisfy the commutation relations

$$[L_x, L_y] = i\hbar L_z,\ [L_y, L_z] = i\hbar L_x \text{ and } [L_z, L_x] = i\hbar L_y. \tag{F.26}$$

These are the generic commutation relations for any type of angular momentum. The Hermitian operators that uniquely define the state of orbital angular momentum are the operators $\mathbf{L}^2$ and L_z. Their shared basis $\{|l, m_l\rangle\}$ is defined by

$$\mathbf{L}^2 \, |l, m_l\rangle = l(l+1)\hbar^2 \, |l, m_l\rangle \tag{F.27a}$$

$$L_z \, |l, m_l\rangle = m_l \hbar \, |l, m_l\rangle \, , \tag{F.27b}$$

where the $|l, m_l\rangle$ are abstract (*i.e.*, representation-free) state vectors in Hilbert space, with l and m_l the *rotational quantum numbers.* The basis $\{|l, m_l\rangle\}$ is called the *standard representation* $\{L^2, L_z\}$ of angular momentum. The spherical harmonics

$$Y_l^{m_l}(\theta, \phi) \equiv Y_l^{m_l}(\hat{\mathbf{r}}) = \langle \hat{\mathbf{r}} | l, m_l \rangle \tag{F.28}$$

are the corresponding wavefunctions in the position representation of spherical coordinates.

F.1.4 Spin coordinates, spinor states and spinorbitals

The "wavefunction" $\chi(\sigma)$ of the spin of a particle in the angular momentum state $|\chi\rangle$ is obtained by projection of $|\chi\rangle$ onto one of the eigenstates $\{|\sigma\rangle\}$ of the s_z operator,

$$\chi(\sigma) = \langle \sigma | \chi \rangle = \sum_{m_s=-s}^{s} \langle \sigma | s, m_s \rangle \langle s, m_s | \chi \rangle, \tag{F.29}$$

where σ assumes discrete values in the interval $s \le \sigma \le s$. Hence, the function $\chi(\sigma)$ is a function of the discrete variable σ, the *spin coordinate.* For a particle in spin state χ the spinor $\chi(\sigma)$ represents the probability amplitude to detect the particle in the eigenstate σ. For s being *half-integral* it is called a $2s+1$ component *spinor* (to distinguish its rotation properties from scalar and vector functions). The basis states are denoted by the unit spinors

$$\chi_{m_s}(\sigma) \equiv \langle \sigma | s, m_s \rangle = \delta_{m_s, \sigma}, \tag{F.30}$$

where m_s assumes discrete values in the interval $s \le m_s \le s$. For the special case of $s = \frac{1}{2}$ the eigenstates are often written in the arrow notation, $\chi_{+1/2}(\sigma) \equiv \chi_{\uparrow}(\sigma)$ and $\chi_{-1/2}(\sigma) \equiv \chi_{\downarrow}(\sigma)$.

As an example we consider the case $s = \frac{1}{2}$, where the summation runs over the values $m_s \in \{-\frac{1}{2}, +\frac{1}{2}\}$,

$$\chi(\sigma) = \chi_{\uparrow}(\sigma) \langle +\tfrac{1}{2} | \chi \rangle + \chi_{\downarrow}(\sigma) \langle -\tfrac{1}{2} | \chi \rangle. \tag{F.31}$$

Note that $\chi(\sigma) = \langle \pm\frac{1}{2} | \chi \rangle$ for $\sigma = \pm\frac{1}{2}$. In the *matrix representation* the $s = \frac{1}{2}$ spinors take the form of a column vector,

$$\chi(\sigma) = \begin{pmatrix} \langle +\frac{1}{2} | \chi \rangle \\ \langle -\frac{1}{2} | \chi \rangle \end{pmatrix} = \langle +\tfrac{1}{2} | \chi \rangle \begin{pmatrix} 1 \\ 0 \end{pmatrix} + \langle -\tfrac{1}{2} | \chi \rangle \begin{pmatrix} 0 \\ 1 \end{pmatrix}. \tag{F.32}$$

and the basis vectors take the form (up to a not observable phase factor)

$$\chi_{\uparrow}(\sigma) = \begin{pmatrix} 1 \\ 0 \end{pmatrix} \quad \text{and} \quad \chi_{\downarrow}(\sigma) = \begin{pmatrix} 0 \\ 1 \end{pmatrix}. \tag{F.33}$$

The spinor concept is readily extended from *discrete spinor* functions to *spinor fields.* Such an extension is essential to describe particles with both motional and spin degrees of freedom (for example the electron). Since $\boldsymbol{s}$ and $\underline{\mathbf{r}}$ are commuting observables they must share a complete set of basis functions, obtained as the *tensor product* of their eigenstates

$$|\mathbf{r}, \sigma\rangle \equiv |\mathbf{r}\rangle \otimes |\sigma\rangle. \tag{F.34}$$

The tensor product assures that for every eigenvalue of one operator the state can assume all eigenvalues of the other operator. An arbitrary state can be written in the form

$$\psi\left(\mathbf{r},\sigma\right)=\langle\mathbf{r},\sigma|\psi\rangle=\varphi\left(\mathbf{r}\right)\chi(\sigma),\tag{F.35}$$

where $\varphi\left(\mathbf{r}\right)=\langle\mathbf{r}|\varphi\rangle$ is the wavefunction in the position representation and $\chi(\sigma)=\langle\sigma|\chi\rangle$ a discrete spinor.

For the case $s=\frac{1}{2}$ this implies

$$\psi\left(\mathbf{r},\sigma\right)=\varphi\left(\mathbf{r}\right)\langle+\tfrac{1}{2}|\chi\rangle\chi_{\uparrow}(\sigma)+\varphi\left(\mathbf{r}\right)\langle-\tfrac{1}{2}|\chi\rangle\chi_{\downarrow}(\sigma).\tag{F.36}$$

In matrix form this becomes

$$\psi\left(\mathbf{r},\sigma\right)=\begin{pmatrix}\psi\left(\mathbf{r},+1/2\right)\\ \psi\left(\mathbf{r},-1/2\right)\end{pmatrix}=\psi\left(\mathbf{r},+1/2\right)\begin{pmatrix}1\\0\end{pmatrix}+\psi\left(\mathbf{r},-1/2\right)\begin{pmatrix}0\\1\end{pmatrix},\tag{F.37}$$

where $\psi\left(\mathbf{r},\pm1/2\right)$ is a *double-valued* function representing the probability amplitude to observe the particle at position $\mathbf{r}$ in spin state $|\pm\frac{1}{2}\rangle$.

If a particle is prepared in the motional state $|\varphi\rangle=|\mathbf{k}\rangle$ and spin state $|\chi\rangle=|\uparrow\rangle$ the Eq. (F.36) takes the form of a *spinorbital*

$$\psi_{\mathbf{k}\uparrow}\left(\mathbf{r},\sigma\right)=\varphi_{\mathbf{k}}\left(\mathbf{r}\right)\chi_{\uparrow}(\sigma).\tag{F.38}$$

In terms of spinorbitals the spinor field becomes

$$\psi\left(\mathbf{r},\sigma\right)=\psi_{\mathbf{k}\uparrow}\left(\mathbf{r},\sigma\right)\chi(+\tfrac{1}{2})+\psi_{\mathbf{k}\downarrow}\left(\mathbf{r},\sigma\right)\chi(-\tfrac{1}{2}),\tag{F.39}$$

where $\chi(\pm\frac{1}{2})$ is the probability amplitude to observe the particle in spin state $\left|\pm\frac{1}{2}\right\rangle$.

F.2 The Schrödinger and Heisenberg pictures of time evolution

In this section we discuss two alternative views on the time evolution in non-relativistic quantum mechanics. These are known as the *Schrödinger* and the *Heisenberg picture*. To introduce these pictures, we start by recalling that the state of a quantum mechanical system is postulated to be *uniquely* defined by a state vector in Hilbert space (see Appendix F.1.1). At any point in time a quantum mechanical state can be written as a linear superposition of eigenstates. This superposition is (in general) not stationary but evolves in time. In the Schrödinger picture we postulate that the time evolution is *uniquely* defined by a *linear* transformation,

$$|\psi_S(t)\rangle=U(t,t_0)|\psi_S(t_0)\rangle,\tag{F.40}$$

where $|\psi_S(t)\rangle$ is the state of the system at time t. The linearity implies that $|\psi_S(t)\rangle$ is given by a linear superposition of *independently* evolving eigenstates; i.e., the superposition is conserved but the coefficients vary in time. The operator $U(t,t_0)$ is called the evolution operator of the system and accounts for the time dependence of the states over the interval $t_0\to t$. By definition $U(t_0,t_0)=1$. To assure the postulated uniqueness of the state evolution, the transformation has to be *norm conserving*,

$$\langle\psi_S(t)|\psi_S(t)\rangle=\langle\psi_S(t_0)|\psi_S(t_0)\rangle.\tag{F.41}$$

Only in this way we can be sure that a system, initially in state $|\psi_S(t_0)\rangle$, arrives with unit probability at time t in the state $|\psi_S(t)\rangle$. Substituting the transformation (F.40) into (F.41), we find that the norm is conserved if and only if $U^{\dagger}U=\mathbb{1}$; i.e., the evolution has to be *unitary*,

$$U^{\dagger}(t,t_0)=U^{-1}(t,t_0)=U(t_0,t).\tag{F.42}$$

In view of the uniqueness of the time evolution, $U(t,t_0)$ can be written as a product of unitary operators,

$$U(t,t_0) = U(t,t_n)U(t_n,t_{n-1})\cdots U(t_2,t_1)U(t_1,t_0). \tag{F.43}$$

This shows that the set $\{U(t,t')\}$ forms a group under multiplication, with unit element $U(t,t)$ and inverse $U(t',t)$. In particular, as t is a continuous variable, $U(t,t_0)$ can be written as an *infinite* product of *infinitesimal* evolution operators $U(t+\delta t,t)$. Infinitesimal unitary operators with the property $U(t,t)=1$ can be expressed in the form

$$U(t+\delta t,t) = \mathbb{1} - (i/\hbar)\mathcal{H}(t)\delta t = e^{-i\mathcal{H}(t)\delta t/\hbar} \quad \text{for } \delta t \to 0, \tag{F.44}$$

where $\mathcal{H}(t)$ has to be a *hermitian* operator to assure the unitarity of U. The factor $1/\hbar$ has been included for future convenience. Note that (for any point in time) the evolution operator commutes with the Hamiltonian,

$$[U(t+\delta t,t),\mathcal{H}(t)] = 0. \tag{F.45}$$

Using $U(t,t)=1$, we rewrite Eq. (F.44) in the form

$$\lim_{\delta t\to 0}\frac{U(t+\delta t,t)-U(t,t)}{\delta t} = -(i/\hbar)\mathcal{H}(t). \tag{F.46}$$

Multiplying both sides with $U(t,t_0)$ we obtain the differential equation [1]

$$i\hbar\frac{\partial}{\partial t}U(t,t_0) = \mathcal{H}(t)U(t,t_0), \tag{F.47}$$

subject to the boundary condition $U=1$ for $t=t_0$. This equation can be rewritten in the form of an integral equation by integration over the finite time interval $t_0 \to t$,

$$U(t,t_0) = \mathbb{1} - (i/\hbar)\int_{t_0}^{t} dt'\mathcal{H}(t')U(t',t_0). \tag{F.48}$$

This form for the evolution operator is particularly suited for generating iterative solutions for application in time-dependent perturbation theory.

As the time dependences of $U(t,t_0)$ and $|\psi_S(t)\rangle$ are related by the equation

$$i\hbar\frac{\partial}{\partial t}|\psi_S(t)\rangle = \left[i\hbar\frac{\partial}{\partial t}U(t,t_0)\right]|\psi_S(t_0)\rangle \tag{F.49}$$

we find for the time dependence of the state vector

$$i\hbar\frac{\partial}{\partial t}|\psi_S(t)\rangle = \mathcal{H}(t)|\psi_S(t)\rangle, \tag{F.50}$$

with the boundary condition that at $t=t_0$ the system is in the state $|\psi_S(t_0)\rangle$. In this differential equation we recognize the familiar form of the time-dependent Schrödinger equation. In view of this formal similarity the hermitian operator $\mathcal{H}$ is called the Hamiltonian of the quantum mechanical system. In hindsight this explains the factor $1/\hbar$ included in Eq. (F.44). This being said, it should be emphasized that Eq. (F.50) was obtained from the postulates without any reference to the Hamilton formalism of classical mechanics. It shows that the Hamiltonian can be defined, *also in the absence of any correspondence to a classical system*, as the hermitian operator that assures unitary evolution of the system.

Recalling that $U(t,t_0)$ can be written as an infinite product of infinitesimal operators we distinguish three cases

---

[1] The time derivative of the operator $U(t,t')$ is defined as

$$\frac{\partial}{\partial t}U(t,t') \equiv \lim_{\delta t\to 0}\frac{U(t+\delta t,t')-U(t,t')}{\delta t}.$$

- *Time-dependent Hamiltonian* with the property $[\mathcal{H}(t),\mathcal{H}(t')] \neq 0$.
$$U(t,t_0) \equiv \lim_{\delta t\to 0} e^{-i\mathcal{H}(t-\delta t)\delta t/\hbar}\cdots e^{-i\mathcal{H}(t_0)\delta t/\hbar} \tag{F.51}$$
- *Time-dependent Hamiltonian* with the property $[\mathcal{H}(t),\mathcal{H}(t')] = 0$. Using the properties of exponential operators (see Appendix L.8)
$$U(t,t_0) \equiv \lim_{\delta t\to 0} e^{-i\mathcal{H}(t-\delta t)\delta t/\hbar}\cdots e^{-i\mathcal{H}(t_0)\delta t/\hbar} = e^{-(i/\hbar)\int_{t_0}^{t}\mathcal{H}(t')dt'} \tag{F.52}$$
- *Time-independent Hamiltonian* $\mathcal{H} = \mathcal{H}_0$ (conservative system). In this case we write $\delta t \equiv (t-t_0)/n$ and obtain with the aid of Eq. (L.33a)
$$U(t,t_0) \equiv \lim_{n\to\infty}\left[e^{-(i/\hbar)\mathcal{H}_0(t-t_0)/n}\right]^n = e^{-i\mathcal{H}(t-t_0)/\hbar}. \tag{F.53}$$

F.2.1 Schrödinger picture

In this section we summarize the primary features of the *Schrödinger picture.* The evolution of the physical system is contained in the time dependence of the state vector,

$$|\psi_S(t)\rangle = U(t,t_0)|\psi_S(t_0)\rangle, \tag{F.54}$$

where $|\psi_S(t)\rangle$ is the *Schrödinger state* of the system at time t. In the Schrödinger picture we write A_S for the operator that represents the dynamical variable A. Likewise, we shall write A_H when turning to the Heisenberg picture. An exception is made for the Hamiltonian because, as we shall see, this operator is the same in both pictures. For this reason we simply write $\mathcal{H}$ rather than $\mathcal{H}_S$ or $\mathcal{H}_H$. The time dependence of the state vectors is governed by the Schrödinger equation,

$$i\hbar\frac{\partial}{\partial t}|\psi_S(t)\rangle = \mathcal{H}(t)|\psi_S(t)\rangle, \tag{F.55}$$

subject to the boundary condition that at $t = t_0$ the system is in the state $|\psi_S(t_0)\rangle$. According to the postulate of quantum measurement (see Appendix F.1.1), the expectation value of $A_S(t)$ is given by

$$\langle A_S(t)\rangle = \frac{\langle\psi_S(t)|A_S(t)|\psi_S(t)\rangle}{\langle\psi_S(t)|\psi_S(t)\rangle}. \tag{F.56}$$

As the evolution is norm conserving, the time derivative of the expectation value is given by - see Problem F.2

$$i\hbar\frac{d}{dt}\langle A_S(t)\rangle = \langle[A_S(t),\mathcal{H}(t)]\rangle + i\hbar\langle\frac{\partial}{\partial t}A_S(t)\rangle. \tag{F.57}$$

Here the first term arises from the time development of the state and the second one from that of the operator. Note that the latter is only nonzero if the operator depends explicitly on time.

Problem F.2. Show that the equation of motion for the expectation value of a (generally time-dependent) operator $A_S(t)$ is given by

$$i\hbar\frac{d}{dt}\langle A_S(t)\rangle = \langle[A_S(t),\mathcal{H}(t)]\rangle + i\hbar\langle\frac{\partial}{\partial t}A_S(t)\rangle.$$

Solution. The answer is obtained by differentiation of (F.56) using the Leibniz integral rule (L.28). Since the norm of the state is conserved we obtain the following three terms,

$$\frac{d}{dt}\langle A_S(t)\rangle = \left[\frac{\partial}{\partial t}\langle\psi_S(t)|\right]A_S(t)|\psi_S(t)\rangle + \langle\psi_S(t)|\left[\frac{\partial}{\partial t}A_S(t)\right]|\psi_S(t)\rangle + \langle\psi_S\,(t)\,|A_S(t)\left[\frac{\partial}{\partial t}|\psi_S(t)\rangle\right].$$

The first and the third term are evaluated using the Schrödinger equation (F.55) and its hermitian conjugate. The second term is zero unless the operator has an explicit time dependence. Thus we obtain

$$i\hbar\frac{d}{dt}\langle A_S(t)|\rangle = -\langle\psi_S(t)|\left[\mathcal{H}(t)A_S(t) - A_S(t)\mathcal{H}(t)\right]|\psi_S(t)\rangle + i\hbar\langle\psi_S(t)|\left[\frac{\partial}{\partial t}A_S(t)\right]|\psi_S(t)\rangle,$$

which can be rewritten in the form of the desired expression. □

F.2.2 Heisenberg picture

The *Heisenberg picture* is obtained by a unitary transformation of the Schrödinger states and operators in the Hilbert space. This unitary transformation is chosen such that it exactly removes the time dependence from the Schrödinger state $|\psi_S(t)\rangle$ by evolving it back to $t = t_0$,

$$|\psi_H\rangle \equiv U^\dagger(t,t_0)|\psi_S(t)\rangle = |\psi_S(t_0)\rangle. \tag{F.58}$$

The same unitary transformation puts a time dependence on the operators,

$$A_H(t) = U^\dagger(t,t_0)A_S(t)U(t,t_0). \tag{F.59}$$

Note that with this transformation the Heisenberg and Schrödinger pictures coincide at $t = t_0$,

$$A_H(t_0) = A_S(t_0) \quad \text{and} \quad |\psi_H\rangle = |\psi_S(t_0)\rangle. \tag{F.60}$$

Importantly, since $U(t,t_0)$ commutes with the Hamiltonian $\mathcal{H}(t)$, the transformation to the Heisenberg picture leaves the Hamiltonian invariant. For this reason we omit the subscript and simply write $\mathcal{H}(t)$. It is straightforward to show, using Eq. (F.56), that the expectation value $\langle A_H\rangle$ coincides with $\langle A_S\rangle$ at any time t and is given by

$$\langle A_H(t)\rangle = \frac{\langle\psi_H|A_H(t)|\psi_H\rangle}{\langle\psi_H|\psi_H\rangle} = \frac{\langle\psi_H|U^\dagger(t,t_0)A_S(t)U(t,t_0)|\psi_H\rangle}{\langle\psi_H|U^\dagger(t,t_0)U(t,t_0)|\psi_H\rangle} = \langle A_S(t)\rangle. \tag{F.61}$$

As, by construction, $|\psi_H\rangle$ does not depend on time, the time dependence of $\langle A_H(t)\rangle$ is fully determined by the time dependence of $A_H(t)$. The latter is known as the the *Heisenberg equation of motion.* By differentiation of (F.59) we obtain - see Problem F.3

$$i\hbar\frac{d}{dt}A_H(t) = [A_H(t),\mathcal{H}(t)] + i\hbar\frac{\partial}{\partial t}A_H(t), \tag{F.62}$$

where

$$\frac{\partial}{\partial t}A_H(t) \equiv \left(\frac{\partial}{\partial t}A_S(t)\right)_H = U^\dagger(t)\left[\frac{\partial}{\partial t}A_S(t)\right]U(t). \tag{F.63}$$

The correspondence (F.61) shows that the Heisenberg equation of motion is completely equivalent to the Schrödinger equation.

Problem F.3. Consider the Heisenberg operator $A_H(t) = U^\dagger(t)A_S(t)U(t)$. Show that the equation of motion of this operator is given by

$$i\hbar\frac{d}{dt}A_H(t) = [A_H(t),\mathcal{H}(t)] + i\hbar\frac{\partial}{\partial t}A_H(t).$$

Solution. By differentiation of $\langle A_H(t)\rangle$ we obtain three terms using the Leibniz integral rule (L.28)

$$\frac{d}{dt}\langle A_H(t)\rangle = \langle\left[\frac{\partial}{\partial t}U^\dagger(t)\right]A_S(t)U(t) + U^\dagger(t)\left[\frac{\partial}{\partial t}A_S(t)\right]U(t) + U^\dagger(t)A_S(t)\left[\frac{\partial}{\partial t}U(t)\right]\rangle.$$

The first and the third term are evaluated using the differential equation (F.47) and its hermitian conjugate. The second term is zero unless the operator has an explicit time dependence. As the Heisenberg states are time independent we can assign all time dependence to the Heisenberg operators,

$$i\hbar\frac{d}{dt}A_H(t) \equiv -U^\dagger(t)\left[\mathcal{H}(t)A_S(t) - A_S(t)\mathcal{H}(t)\right]U(t) + i\hbar U^\dagger(t)\frac{\partial}{\partial t}A_S(t)U(t).$$

As $\mathcal{H}(t)$ commutes with the evolution operator this expression simplifies to

$$i\hbar\frac{d}{dt}A_H(t) = [A_H(t),\mathcal{H}(t)] + i\hbar U^\dagger(t)\frac{\partial}{\partial t}A_S(t)U(t).$$

Defining

$$\frac{\partial}{\partial t}A_H(t) \equiv \left(\frac{\partial}{\partial t}A_S(t)\right)_H \equiv U^\dagger(t)\left[\frac{\partial}{\partial t}A_S(t)\right]U(t)$$

we arrive at the desired expression. □

F.2.3 Interaction picture

Rather than removing the full time dependence, we can also use a unitary transformation that removes only part of it. It may speak for itself that this can be done in many ways. A particularly valuable variant arises when the Hamiltonian of the system can be separated into two parts,

$$\mathcal{H}(t) = \mathcal{H}_0 + \mathcal{H}_1(t), \tag{F.64}$$

where $\mathcal{H}_0$ is the time-independent Hamiltonian of a closed system and $\mathcal{H}_1(t)$ is a (generally time-dependent) perturbation representing some interaction with an external field. To analyze this case, we consider the unitary transformations

$$|\psi_I(t)\rangle = U_0^\dagger(t)|\psi_S(t)\rangle, \tag{F.65}$$

and

$$A_I(t) = U_0^\dagger(t)A_S(t)U_0(t). \tag{F.66}$$

Here $U_0(t)$ is the evolution operator corresponding to $\mathcal{H}_0$,

$$U_0(t) = e^{-i\mathcal{H}_0(t-t_1)/\hbar}, \tag{F.67}$$

which is the solution of the differential equation

$$i\hbar\frac{\partial}{\partial t}U_0(t) = \mathcal{H}_0U_0(t), \tag{F.68}$$

under the boundary condition $U_0(t) = 1$ for $t = t_1$. With this definition, the state $|\psi_I(t_1)\rangle$ coincides with the Schrödinger state $|\psi_S(t)\rangle$ for $t = t_1$. As we are free to choose the time t_1, we conveniently choose $t_0 = 0$.

The above transformations define the *interaction* picture and the states $|\psi_I(t)\rangle$ are called the *intermediate* states. The operator $A_I(t)$ is called the *intermediate* operator. Note that $U_0(t)$ removes all $\mathcal{H}_0$-related evolution from the state but leaves the part related to $\mathcal{H}_1(t)$. For small $\mathcal{H}_1(t)$ this means that $|\psi_I(t)\rangle$ is "almost" stationary. It follows with the aid of Eqs. (F.65) and (F.56) that the expectation values $\langle A_I\rangle$ and $\langle A_S\rangle$ coincide at all times,

$$\langle A_I\,(t)\rangle = \frac{\langle\psi_I(t)|A_I(t)|\psi_I(t)\rangle}{\langle\psi_I(t)|\psi_I(t)\rangle} = \frac{\langle\psi_I(t)|U_0^\dagger(t)A_S(t)U_0(t)|\psi_I(t)\rangle}{\langle\psi_I(t)|U_0^\dagger(t)U_0(t)|\psi_I(t)\rangle} = \langle A_S(t)\rangle. \tag{F.69}$$

The time dependence of the intermediate states can be obtained by differentiation of Eq. (F.65) - see Problem F.4,

$$i\hbar\frac{\partial}{\partial t}|\psi_I(t)\rangle = \mathcal{H}_I(t)|\psi_I(t)\rangle, \tag{F.70}$$

where $\mathcal{H}_I(t)$ is defined by

$$\mathcal{H}_I(t) \equiv U_0^\dagger(t)\mathcal{H}_1(t)U_0(t), \tag{F.71}$$

which is consistent with the general case (F.66). In complete analogy with the derivation of the Heisenberg equation of motion we obtain by differentiation of (F.66) the *intermediate* equation of motion,

$$i\hbar\frac{d}{dt}A_I(t) = [A_I(t), \mathcal{H}_0] + i\hbar\frac{\partial}{\partial t}A_I(t), \tag{F.72}$$

where

$$\frac{\partial}{\partial t}A_I(t) \equiv \left(\frac{\partial}{\partial t}A_S(t)\right)_I = U_0^\dagger(t)\left[\frac{\partial}{\partial t}A_S(t)\right]U_0(t). \tag{F.73}$$

Hence, just like the time evolution of A_H follows from the full Hamiltonian, the time dependence of A_I follows from the partial Hamiltonian $\mathcal{H}_0$.

As also the time evolution driven by $\mathcal{H}_I(t)$ has to be uniquely defined the evolution of the intermediate state over the interval $t_0 \to t$ can be written in the form

$$|\psi_I(t)\rangle = U_I(t,t_0)|\psi_I(t_0)\rangle, \tag{F.74}$$

where $U_I(t,t_0)$ is a *unitary* operator and the solution of the differential equation

$$i\hbar\frac{\partial}{\partial t}U_I(t,t_0) = \mathcal{H}_I(t)U_I(t,t_0), \tag{F.75}$$

under the boundary condition $U_I(t_0,t_0) = 1$. This differential equation can be rewritten in the form of an integral equation,

$$U_I(t,t_0) = 1 - \frac{i}{\hbar}\int_{t_0}^{t} dt_1 \mathcal{H}_I(t_1)U_I(t_1,t_0). \tag{F.76}$$

In search for a relation between $U_I(t,t_0)$ and $U(t,t_0)$ we write, with the aid of Eqs. (F.65) and (F.54), the intermediate state in the form

$$|\psi_I(t)\rangle = U_0^\dagger(t)|\psi_S(t)\rangle = U_0^\dagger(t)U(t,t_0)|\psi_S(t_0)\rangle = U_0^\dagger(t)U(t,t_0)U_0(t_0)|\psi_I(t_0)\rangle. \tag{F.77}$$

Comparing this expression with Eq. (F.65) we obtain the following relation between the full and the intermediate evolution operator,

$$U_I(t,t_0) = e^{i\mathcal{H}_0 t/\hbar}U(t,t_0)e^{-i\mathcal{H}_0 t/\hbar}. \tag{F.78}$$

Note that in the intermediate picture the time dependence is divided between the states and the operators. Its operators resemble the Heisenberg operators - compare Eqs. (F.62) and (F.72), whereas its states resemble the Schrödinger states - compare Eqs. (F.55) and (F.70).

Problem F.4. Show that the equation of motion for the expectation value of a (generally time-dependent) intermediate operator $A_I(t)$ is given by

$$i\hbar\frac{\partial}{\partial t}|\psi_I(t)\rangle = \mathcal{H}_I(t)|\psi_I(t)\rangle.$$

Solution. Differentiating (F.65) we obtain with the aid of Eqs. (F.68) and (F.55)

$$\begin{aligned} i\hbar\frac{\partial}{\partial t}|\psi_I(t)\rangle &= \left[\frac{\partial}{\partial t}U_0^\dagger(t)\right]|\psi_S(t)\rangle + i\hbar U_0^\dagger(t)\frac{\partial}{\partial t}|\psi_S(t)\rangle \\ &= -\mathcal{H}_0 U_0^\dagger(t)|\psi_S(t)\rangle + U_0^\dagger(t)\mathcal{H}(t)|\psi_S(t)\rangle. \end{aligned}$$

Using Eq. (F.65) and its inverse, this becomes

$$i\hbar\frac{\partial}{\partial t}|\psi_I(t)\rangle = -\mathcal{H}_0|\psi_I(t)\rangle + U_0^\dagger(t)\mathcal{H}(t)U_0(t)|\psi_I(t)\rangle.$$

Since $\mathcal{H}_0 = U_0^\dagger(t)\mathcal{H}_0 U_0(t)$ and $\mathcal{H}_1(t) = \mathcal{H}(t) - \mathcal{H}_0$ this corresponds to

$$i\hbar\frac{\partial}{\partial t}|\psi_I(t)\rangle = U_0^\dagger(t)\mathcal{H}_1(t)U_0(t)|\psi_I(t)\rangle.$$

Defining $\mathcal{H}_I(t) \equiv U_0^\dagger(t)\mathcal{H}_1(t)U_0(t)$ we arrive at the desired form. □

F.2.4 Constants of the motion and "good" quantum numbers

The dynamical variable A of a quantum mechanical system is called a *constant of the motion* if the expectation value $\langle A_S\rangle$ is independent of time, whatever the state of the system. This implies that the Heisenberg operator A_H is stationary as follows by differentiation of (F.61),

$$\frac{d}{dt}\langle A_S\rangle = \langle \frac{d}{dt}A_H\rangle \equiv 0 \quad \Rightarrow \quad \frac{d}{dt}A_H = 0. \tag{F.79}$$

Furthermore, expressing the Heisenberg equation of motion for the operator A_H in terms of the corresponding Schrödinger operator A_S we find with the aid of Eqs. (F.62) and (F.45)

$$i\hbar\frac{d}{dt}A_H = U^\dagger(t,t_0)[A_S,\mathcal{H}]U(t,t_0) + i\hbar U^\dagger(t)\left[\partial A_S(t)/\partial t\right]U(t). \tag{F.80}$$

This shows that the dynamical variable A is a constant of the motion if A_S does not depend explicitly on time, $\partial A_S(t)/\partial t = 0$, and commutes with the Hamiltonian, $[A_S,\mathcal{H}] = 0$.

In particular, suppose that at $t = t_0$ the system is in the eigenstate $|a\rangle$ of A_S with eigenvalue a. In this case we have $\langle A_S\rangle = a$ and a is called a "good" quantum number if this expectation value is conserved in time. This invariance is satisfied if $|a\rangle$ is also an eigenstate of $\mathcal{H}$ (i.e., if $[A_S,\mathcal{H}] = 0$). If a is a good quantum number the time development of the state is given by

$$|\psi(t)\rangle = \exp[-(i/\hbar)\varepsilon_a(t-t_0)]\,|a\rangle\,, \tag{F.81}$$

where $\exp[-(i/\hbar)\varepsilon_a(t-t_0)]$ is called the *dynamical phase* of the state. This shows explicitly that eigenstates are stationary up to the development of the dynamical phase.

To illustrate these concepts we consider a quantum mechanical system at $t = 0$ in the state

$$|\psi_0\rangle = |a\rangle = \sqrt{1/2}\,(|\alpha\rangle + |\beta\rangle)\,, \tag{F.82}$$

which is itself *not* an eigenstate of $\mathcal{H}$ but a linear combination of the (normalized) eigenstates $|\alpha\rangle$ and $|\beta\rangle$ of $\mathcal{H}$ with eigenvalues ε_a and ε_b, respectively. By integrating the time-dependent Schrödinger equation we obtain for the time dependence of the state

$$|\psi(t)\rangle = e^{-(i/\hbar)\mathcal{H}t}\,|a\rangle = \sqrt{1/2}\left[e^{-(i/\hbar)\varepsilon_\alpha t}\,|\alpha\rangle + e^{-(i/\hbar)\varepsilon_\beta t}\,|\beta\rangle\right]. \tag{F.83}$$

Note that for $t = 0$ we regain Eq. (F.82). Projecting $|\psi(t)\rangle$ onto the state $|a\rangle$ we find that the occupation of $|a\rangle$ will oscillate in time between 1 and 0 at the frequency corresponding to the energy splitting $\varepsilon_a - \varepsilon_b$ between the levels,

$$|\langle a\,|\psi(t)\rangle\,|^2 = \tfrac{1}{2} + \tfrac{1}{2}\cos[(\varepsilon_\alpha - \varepsilon_\beta)\,t/\hbar]. \tag{F.84}$$

Note that the Hamiltonian is a constant of the motion,

$$\langle\psi(t)|\mathcal{H}\,|\psi(t)\rangle = \tfrac{1}{2}\,(\varepsilon_\alpha + \varepsilon_\beta)\,. \tag{F.85}$$

Let us specialize to the case that the initial state $|a\rangle$ is an eigenstate of the operator A, with eigenvalue a,

$$A\,|a\rangle = a\,|a\rangle\,. \tag{F.86}$$

When is A is constant of the motion (and a a good quantum number)?

- If $[A,\mathcal{H}] = 0$ we find with the aid of Eq. (L.33b),

$$\langle\psi(t)|A\,|\psi(t)\rangle = \langle a|\,e^{(i/\hbar)\mathcal{H}t}Ae^{-(i/\hbar)\mathcal{H}t}\,|a\rangle = a. \tag{F.87}$$

Hence, in this case A is a constant of the motion (and a is a good quantum number).

- If $[A, \mathcal{H}] = -B \neq 0$ we find with the aid of Eq. (L.33b)

$$\begin{aligned}\langle\psi(t)|A\,|\psi(t)\rangle &= \langle a|\,e^{(i/\hbar)\mathcal{H}t}Ae^{-(i/\hbar)\mathcal{H}t}\,|a\rangle \\ &= a + (i/\hbar)\,\langle a|\,B\,|a\rangle\,t + \tfrac{1}{2!}(i/\hbar)^2\,\langle a|\,[\mathcal{H}, B]\,|a\rangle\,t^2 + \cdots .\end{aligned} \tag{F.88}$$

Hence, in this case A is *not* a constant of the motion (and a *not* a good quantum number).

Problem F.5. Show by explicit calculation the equivalence of the Heisenberg equation of motion and the Schrödinger equation for the example of a particle of mass m moving in the conservative potential energy field $\mathcal{V}(\mathbf{r})$.

Solution. At $t = 0$ the particle is in the state $|\psi_H\rangle$. As the Hamiltonian does not depend on time and the position operator $\underline{\mathbf{r}}$ does not depend *explicitly* on time, the time development of the Heisenberg position operator $\mathbf{r}(t) = \mathbf{r}_H(t)$ is given by Eq. (F.80) in the form

$$i\hbar\frac{d}{dt}\mathbf{r}(t) = [\mathbf{r}(t), \mathcal{H}], \text{ with } \mathcal{H} = -\frac{\underline{\mathbf{p}}^2}{2m} + \mathcal{V}(\underline{\mathbf{r}}).$$

Using $\mathbf{r}(t) = U^{\dagger}(t, t_0)\underline{\mathbf{r}}U(t, t_0)$ and recalling Eqs. (F.45) and (F.47) we have

$$i\hbar\frac{d}{dt}U^{\dagger}(t, t_0)\underline{\mathbf{r}}U(t, t_0)\,|\psi_H\rangle = U^{\dagger}(t, t_0)[\underline{\mathbf{r}}, \mathcal{H}]U(t, t_0)\,|\psi_H\rangle\,.$$

Multiplying from the left with $U(t, t_0)$ and turning to Schrödinger states this becomes

$$i\hbar U(t, t_0)\frac{d}{dt}U^{\dagger}(t, t_0)\underline{\mathbf{r}}\,|\psi(t)\rangle = [\underline{\mathbf{r}}, \mathcal{H}]\,|\psi(t)\rangle$$

With the aid of the differential equation (F.47) this becomes

$$-\mathcal{H}\underline{\mathbf{r}}\,|\psi(t)\rangle + i\hbar\frac{d}{dt}\underline{\mathbf{r}}\,|\psi(t)\rangle = [\underline{\mathbf{r}}, \mathcal{H}]\,|\psi(t)\rangle\,.$$

Turning to the position representation this becomes the Schrödinger equation,

$$i\hbar\frac{d}{dt}\langle\mathbf{r}\,|\psi(t)\rangle = \mathcal{H}_0\langle\mathbf{r}\,|\psi(t)\rangle\,, \quad \text{with} \quad \mathcal{H}_0 = \langle\mathbf{r}|\mathcal{H}|\mathbf{r}\rangle = -\frac{\hbar^2}{2m}\Delta + \mathcal{V}(\mathbf{r}). \qquad \square$$

F.2.5 Translation as an example of a symmetry operation

In Appendix D.5.3 we introduced the *homogeneity of space* in relation to conservation laws. The evolution of a *closed* mechanical system only depends on the internal state of that system and not on the inertial frame in which the state is observed in space and time. Now let us suppose that the quantum mechanical state of the system is given by de wavefunction

$$\psi(\mathbf{r}) = \langle\mathbf{r}|\psi\rangle,$$

where $\mathbf{r}$ is the position with respect to a cartesian coordinate system $\mathcal{S}$. We now consider a *passive* translation T of the cartesian coordinate system $\mathcal{S}$ defined by the displacement vector $\mathbf{d}$. Denoting the translated coordinate system by $\mathcal{S}' = T\mathcal{S}$, the position $\mathbf{r} = (x, y, z)$ with respect to $\mathcal{S}$ changes into $\mathbf{r}' = (x', y', z')$ with respect to $\mathcal{S}'$, where

$$\mathbf{r}' = T\,\mathbf{r} = \mathbf{r} - \mathbf{d}. \tag{F.89}$$

As the translation is passive the physical state of the system is not affected by the translation, we require

$$\psi'(\mathbf{r}') \equiv \psi(\mathbf{r}), \tag{F.90}$$

or, equivalently,

$$\psi'(\mathbf{r}) = \psi(\mathbf{r} + \mathbf{d}). \tag{F.91}$$

The appearance of the new state ψ' does not come as a surprise. From general quantum mechanics we know that a new coordinate system comes with a new linear combination of eigenstates, $|\psi'\rangle$, which is related to the original linear combination of eigenstates, $|\psi\rangle$, by a *norm-conserving* basis transformation,

$$|\psi'\rangle = \underline{u}|\psi\rangle. \tag{F.92}$$

The transformation $\underline{u}$ has to be norm conserving because $|\psi\rangle$ and $|\psi'\rangle$ represent the *same* state with respect to two *different* bases,

$$\langle\psi|\psi\rangle = \langle\psi'|\psi'\rangle = \langle\psi|\underline{u}^{\dagger}\underline{u}|\psi\rangle \rightarrow \underline{u}^{\dagger}\underline{u} = \mathbb{1}. \tag{F.93}$$

This identity shows that the transformation must be unitary, $\underline{u}^{\dagger} = \underline{u}^{-1}$, which implies that the inverse transformation is given by

$$|\psi\rangle = \underline{u}^{\dagger}|\psi'\rangle. \tag{F.94}$$

So let us consider the wavefunction of a *free particle*,

$$\psi'(x) = \underline{u}(\Delta x)\psi(x)$$

$$\begin{aligned}\psi'(x) &= \psi(x+\Delta x)\\ &= \psi(x) + \Delta x\partial_x\psi(x) + \tfrac{1}{2!}\Delta x^2\partial_x^2\psi(x) + \cdots\\ &= e^{\Delta x\partial_x}\psi(x)\end{aligned}$$

F.3 Density matrix formalism

F.3.1 Density operators for pure states

The *density matrix formalism* provides an alternative for the familiar representation of quantum mechanical states by linear combinations of eigenvectors spanning a Hilbert space. The central quantity of the density matrix formalism is the *density operator.* For a quantum mechanical system in the state $|\psi(t)\rangle$ the density operator is defined as

$$\rho(t) \equiv |\psi(t)\rangle\langle\psi(t)|. \tag{F.95}$$

Note that this operator is *hermitian,* $\rho^{\dagger} = \rho$, as well as *idempotent,* $\rho^2 = \rho$. The operator ρ can be represented by a (in general *nondiagonal*) square matrix, $\rho_{ij} = \langle i|\rho|j\rangle$, which explains the use of the names *density operator* and *density matrix.* Being hermitian, ρ is free of the phase ambiguity of the state vectors; i.e., a quantum mechanical state is fully defined by its density matrix. As the state kets satisfy the Schrödinger equation (F.50) and the state bras its complex conjugate we have for a time-independent Hamiltonian

$$i\hbar\frac{\partial\rho(t)}{\partial t} = \mathcal{H}|\psi(t)\rangle\langle\psi(t)| - |\psi(t)\rangle\langle\psi(t)|\mathcal{H} = -[\rho(t),\mathcal{H}]. \tag{F.96}$$

Apparently, the density matrix is stationary, $\partial\rho(t)/\partial t = 0$, if it commutes with the Hamiltonian. This has the important consequence that *a stationary density matrix is diagonal in the representation of $\mathcal{H}$.* Furthermore, by diagonalization of a given density matrix we obtain the state of the system and its eigenvalue is unity; i.e., the state of the system is the solution of the eigenvalue equation

$$\rho|\psi\rangle = \rho_0|\psi\rangle \tag{F.97}$$

with eigenvalue $\rho_0 = 1$. In this state, the expectation value of the density operator is unity,

$$\langle\rho\rangle = \langle\psi|\rho|\psi\rangle = 1. \tag{F.98}$$

To demonstrate the calculation of properties of the system in state $|\psi\rangle$, we ask for the *expectation value* of an *arbitrary* operator A,

$$\langle A\rangle = \langle\psi|A|\psi\rangle. \tag{F.99}$$

In some *arbitrarily chosen* alternative representation $\{B\}$, this expectation value can be rewritten (using the closure relation) in the form

$$\langle A\rangle = \sum_i \langle\psi|A|b_i\rangle\langle b_i|\psi\rangle = \sum_i \langle b_i|\psi\rangle\langle\psi|A|b_i\rangle. \tag{F.100}$$

Recognizing the density operator $\rho = |\psi\rangle\langle\psi|$ we find that the expectation value of A for the system in the state $|\psi\rangle$ is given by

$$\langle A\rangle = \sum_i \langle b_i|\rho A|b_i\rangle = \operatorname{tr}\rho A. \tag{F.101}$$

Note that $\operatorname{tr}\rho A = \operatorname{tr} A\rho$. As the representation $\{B\}$ was chosen arbitrarily, the trace is invariant under unitary transformation (a property of square matrices - see Appendix M.2.1). This is expressed by the representation-free form of Eq. (F.101).

To compare the two formalisms a bit further, we reconsider the Parseval relation for the state $|\psi\rangle$ in the representation $\{B\}$,

$$1 = \sum_i |\langle b_i|\psi\rangle|^2 = \sum_i \mathcal{P}_i, \tag{F.102}$$

where

$$\mathbb{1} = \sum_i |b_i\rangle\langle b_i| = \sum_i \rho_i \tag{F.103}$$

is the closure relation in the representation $\{B\}$ and $\mathcal{P}_i$ represents the probability density to observe the system in the eigenstate $|b_i\rangle$. In the *state formalism* we write

$$\mathcal{P}_i = \langle\psi|b_i\rangle\langle b_i|\psi\rangle = \langle\psi|\rho_i|\psi\rangle, \tag{F.104}$$

which is interpreted as the expectation value of the projection operator $\rho_i = |b_i\rangle\langle b_i|$. In the *density matrix formalism*, $\mathcal{P}_i$ is interpreted as the *expectation value of the density operator*,[1]

$$\mathcal{P}_i = \langle b_i|\psi\rangle\langle\psi|b_i\rangle = \langle b_i|\rho|b_i\rangle = \rho_{ii}. \tag{F.105}$$

The representation $\{B\}$ being arbitrary, the Parseval relation takes the representation-free form

$$\operatorname{tr}\rho = 1. \tag{F.106}$$

F.3.2 Density operators for mixed ensembles of states

The importance of the density matrix formalism finds its origin in the probabilistic nature of quantum mechanical measurement. A *single* state-selective measurement (state *filtration*) on a quantum mechanical system is of little value. It tells us whether or not the selected state was observed but nothing more. Only by repeating the measurement many times we can determine the probability of observing that state. If the measurements are done on an ensemble of identically prepared systems, say a beam of particles all prepared in the state $|\psi\rangle$, the probability density of observing this state, $\mathcal{P}_s = |\langle s|\psi\rangle|^2$, is obtained by averaging over the set of measurements. This procedure is called the *ensemble-averaging*. As was shown at the end of the previous section, formally $\mathcal{P}_s$ can be expressed as the *expectation value of the density operator* for the system in state $|s\rangle$, $\mathcal{P}_s = \langle s|\rho|s\rangle$. Such an ensemble of identically prepared systems is called a *pure ensemble*, to distinguish it from *mixed*

---

[1] Notice the difference between the density operator ρ_i and the diagonal matrix element of the density matrix, ρ_{ii}. In our notation $\mathcal{P}_i = \langle\psi|\rho_i|\psi\rangle = \langle\psi|b_i\rangle\langle b_i|\psi\rangle = \langle b_i|\psi\rangle\langle\psi|b_i\rangle = \langle b_i|\rho|b_i\rangle = \rho_{ii}$.

ensembles, in which the state preparation may vary or is even absent.[1] It may speak for itself that whatever the ensemble we can always determine ensemble averages. Therefore, to refer to an arbitrary type of ensemble averaging we use a different notation for the density matrix, $\rho \to \varrho$, denoting the ensemble-averaged probability to detect the state $|s\rangle$ by $\langle s|\varrho|s\rangle$. If there is no state preparation whatsoever one speaks of a *random ensemble* and $\langle s|\varrho|s\rangle = 1/n$, where n is the order of the density matrix. The value of n cannot exceed the number of measurements but it can be smaller. For instance, measuring spin "up" or "down" on a beam of particles we can do many measurements but $n = 2$.

The relative probability of occurrence of one of the states of a mixed ensemble $\{|s\rangle\}$ is given by the statistical weight w_s, a number between zero and one ($0 \le w_s \le 1$), and subject to the normalization condition

$$\sum_s w_s = 1. \tag{F.107}$$

Here, the probability is defined for a discrete ensemble but can be generalized to the continuous case. Note that orthogonality is neither mentioned nor required for the states of the ensemble $\{|s\rangle\}$.

Let us analyze ensemble averaging in more detail. Knowing the probabilities $\{w_s\}$, we can calculate the *quantum statistical average* for an arbitrary operator A,

$$\bar{A} \equiv \langle\!\langle A\rangle\!\rangle = \sum_s w_s \langle s|A|s\rangle. \tag{F.108}$$

Note that this is the *ensemble average* of the expectation values $\langle A\rangle_s = \langle s|A|s\rangle = A_{ss}$. Choosing an arbitrary representation $\{B\}$, we can use its closure relation to write the quantum-statistical average in the form

$$\bar{A} = \sum_s w_s \sum_i \langle s|A|b_i\rangle\langle b_i|s\rangle = \sum_i \sum_s w_s \langle b_i|s\rangle\langle s|A|b_i\rangle = \sum_i \langle b_i|\varrho A|b_i\rangle, \tag{F.109}$$

where

$$\varrho \equiv \sum_s w_s |s\rangle\langle s| = \sum_s w_s \rho_s \tag{F.110}$$

defines the *statistical operator* of the ensemble defined by the weights $\{w_s\}$, which represents the (by construction *diagonal*) density matrix of a *statistical mixture of states.* Importantly, as for a time-independent mixture the weights $\{w_s\}$ are conserved, it follows in the same way as demonstrated for Eq. F.96 that the time dependence of its density matrix is given by

$$i\hbar \frac{\partial \varrho(t)}{\partial t} = -[\varrho(t), \mathcal{H}]. \tag{F.111}$$

Thus we established that (also) for *mixed* ensembles a *stationary* density matrix is *diagonal* in the representation of $\mathcal{H}$.

Using the statistical operator the quantum statistical average can be written in the representation-free form

$$\bar{A} \equiv \langle\!\langle A\rangle\!\rangle = \operatorname{tr} \varrho A. \tag{F.112}$$

Substituting $A \to \mathbb{1}$ we find that for mixed ensembles the Parseval relation (F.106) is replaced by

$$\operatorname{tr} \varrho = 1. \tag{F.113}$$

---

[1] We distinguish between a *mixed ensemble*, which consists of a statistical mixture of states, and a *mixed state*, which is a coherent superposition of states. Beware that some authors use mixed state as an abbreviation for "statistical mixture of states".

Substituting $A \to \rho_s \equiv |s\rangle\langle s|$ we obtain the probability to observe the (pure) state $|s\rangle$ in a measurement on the ensemble,

$$\bar{\rho}_s = \mathrm{tr}\,\varrho\rho_s = \sum_i \langle b_i|\varrho|s\rangle\langle s|b_i\rangle = \langle s|\varrho|s\rangle = \varrho_{ss} = w_s. \tag{F.114}$$

Thus, using the density matrix for mixed ensembles of states, we can calculate quantum statistical averages using the same methods as used for the density matrix of pure states - see Eq. (F.101).[1] The density matrix of a pure state is in general nondiagonal, whereas that of mixed states is by construction diagonal. Furthermore, an important difference is revealed when calculating $\mathrm{tr}\,\varrho^2$. For *pure* states the density matrix is idempotent, $\rho^2 = \rho$, and we have

$$\mathrm{tr}\,\rho^2 = \mathrm{tr}\,\rho = 1. \tag{F.115}$$

For *mixed* states this is replaced by the inequalities.

$$0 \le \mathrm{tr}\,\varrho^2 \le (\mathrm{tr}\,\varrho)^2 = 1. \tag{F.116}$$

F.3.3 Density matrices for quantum-statistical mixtures

Thus far we emphasized ensemble averaging for a real set of measurements; e.g., of the spin states of particles in a beam. Such ensembles of experimental data are called *real* ensembles. Interestingly, density matrices based on *fictitious* ensembles are at least as important. In many-body systems it is simply impossible to measure all particles individually but, as is well known from statistical physics, often this is not necessary. For instance, to calculate the pressure of an ideal gas, all we need to know is the probability of occupation of the single-particle states and this information can be provided by a *fictitious* ensemble such as the canonical distribution over the energy eigenstates of a physical system.

To start the discussion of quantum statistical ensembles we define the entropy of a physical system in terms of its density matrix

$$S/k_B = -\mathrm{tr}\,\varrho\,\mathrm{ln}\varrho. \tag{F.117}$$

To explore the plausibility of this definition as a measure for the disorder in the system we choose the representation of $\mathcal{H}$ (in which ϱ is diagonal - see Section F.3.2). Denoting the basis of this representation by $\{|s\rangle\}$ the expression for the entropy can be written in the form

$$S/k_B = -\sum_{s,s'} \langle s|\varrho|s'\rangle\langle s'|\mathrm{ln}\varrho|s\rangle = -\sum_s \langle s|\varrho|s\rangle \mathrm{ln}\langle s|\varrho|s\rangle = -\sum_s \varrho_{ss}\ln\varrho_{ss}. \tag{F.118}$$

From classical statistical mechanics we recall that zero entropy corresponds to the system being in a single microstate. In quantum statistics this translates to the system being in a pure state. Denoting this pure state by $|\psi\rangle$, its density operator is given by $\varrho = \rho = |\psi\rangle\langle\psi|$ and

$$\varrho_{ss} = \langle s|\varrho|s\rangle = |\langle s|\psi\rangle|^2. \tag{F.119}$$

To avoid the complications of entanglement we restrict ourselves to a single eigenstate of the representation $\{|s\rangle\}$, $|\psi\rangle \to |t\rangle \in \{|s\rangle\}$. In this case we have $\varrho_{ss} = \delta_{s,t}$ and calculate zero entropy, $S = 0$, because either $\varrho_{ss} = 0$ or $\ln\varrho_{ss} = 0$. On the other hand, for a completely random ensemble (where all energy eigenstates have the same probability), the density matrix is given by $\varrho = 1/n$, where n is the size of the ensemble (the order of the density matrix),

$$S/k_B = -\mathrm{tr}\,\frac{1}{n}\,\mathrm{ln}\frac{1}{n} = \ln n. \tag{F.120}$$

---

[1] Many authors do not distinguish between $\langle\!\langle A\rangle\!\rangle$ and $\langle A\rangle$ as all relevant information is contained in the form of ϱ.

For example, the maximum entropy of a two-level system is $\ln 2$.

In general a statistical mixture will not have maximum entropy. We know from the *statistical principle* for ergodic systems that only states of *equal energy* have to be equally probable. This limits the entropy because, at finite temperature, high-energy states will be less probable. In statistical physics the entropy is determined by a maximization procedure in which one or more constraints are enforced. In a canonical ensemble we search for the maximum entropy under the constraints of given total total energy $E = \langle \mathcal{H} \rangle = \mathrm{tr}\, \varrho \mathcal{H}$ and unit normalization, $\mathcal{N} = \mathrm{tr}\, \varrho = 1$. To describe the procedure, we turn to the representation of $\mathcal{H}$, denoted by $\{|s\rangle\} = \{|1\rangle, \cdots, |n\rangle\}$, because in this representation the density matrix is diagonal. For the sake of the argument we restrict ourselves to discrete systems with a finite-dimensional Hilbert space. The lagrangian for the variation of the diagonal elements of the density matrix $\{\varrho_{ss}\}$, and the multipliers β (for total energy) and γ (for normalization) is stationary if the following conditions are satisfied - see Problem F.6

$$\delta L = \sum_{s=1}^{n} \delta \varrho_{ss} \left[-(\ln \varrho_{ss} + 1) - \beta E_s - \gamma \right] = 0, \tag{F.121a}$$

$$\delta E = \sum_{s=1}^{n} \varrho_{ss} E_s - E = 0, \tag{F.121b}$$

$$\delta \mathcal{N} = \sum_{s=1}^{n} \varrho_{ss} - 1 = 0, \tag{F.121c}$$

where $E_s = \langle s|\mathcal{H}|s\rangle$ is the energy of the eigenstate $|s\rangle$. To assure that Eq. (F.121a) be valid for *arbitrary* variations of $\{\delta \varrho_{ss}\}$, we require

$$[(\ln \varrho_{ss} + 1) + \beta E_s + \gamma] = 0. \tag{F.122}$$

Renaming the Lagrange multiplier $\gamma \to -(1 + \beta F)$ we obtain

$$\ln \varrho_{ss} = -\beta(E_s - F), \tag{F.123}$$

which can be written in the form

$$\varrho_{ss} = e^{-\beta(E_s - F)} = \frac{1}{Z} e^{-\beta E_s}. \tag{F.124}$$

Hence, the corresponding density matrix can be defined in the form of a statistical operator,

$$\varrho = \frac{1}{Z} e^{-\beta \mathcal{H}}. \tag{F.125}$$

Imposing the normalization condition (F.121c) we find

$$Z = e^{-\beta F} = \sum_{s=1}^{n} e^{-\beta E_s}. \tag{F.126}$$

By identifying $\beta \equiv 1/k_B T$, we recognize the well-known expression for the canonical partition sum. Note that in the high-temperature limit ($\beta \to 0$) we obtain $Z = n$ and $\varrho_{ss} = 1/n$, which shows that the limiting value for the entropy is that of a random ensemble, $S = \ln n$.

For finite temperature we find for the entropy

$$S/k_B = -\sum_{s=1}^{n} \varrho_{ss} \ln \varrho_{ss} = \beta \sum_{s=1}^{n} \varrho_{ss}(E_s - F) = \beta(E - F), \tag{F.127}$$

where we used Eq. (F.121b). Identifying F with the Helmholtz free energy and E with the internal energy U we obtain the thermodynamic relation

$$F = U - TS. \tag{F.128}$$

Problem F.6. Show that the deviation of the lagrangian of the canonical ensemble of size n vanishes under variation of the $\{\varrho_{ss}\}$, with $s \in \{1, \cdots n\}$ if

$$\delta L = \sum_{s=1}^{n} \delta\varrho_{ss}\, [-(\ln \varrho_{ss} + 1) - \beta E_s - \gamma] = 0.$$

Solution. The lagrangian for the variation of the $\{\varrho_{ss}\}$ of the canonical ensemble under the constraints of fixed total total energy $E = \langle \mathcal{H} \rangle = \mathrm{tr}\, \varrho \mathcal{H}$ and normalization, $\mathrm{tr}\, \varrho = 1$, is given by

$$L(\{\varrho_{ss}\}_n, \beta, \gamma) = \sum_{s=1}^{n} \left[-\varrho_{ss} \ln \varrho_{ss} + \beta(E - \varrho_{ss} E_s) + \gamma(1 - \varrho_{ss}) \right].$$

Hence, L is stationary under partial variation of ϱ_{ss} provided

$$\frac{\delta L}{\delta \varrho_{ss}} = -(\ln \varrho_{ss} + 1) - \beta E_s - \gamma = 0$$

and also stationary under partial variation of β and γ provided

$$\frac{\delta L}{\delta \beta} = E - \sum_{s=1}^{n} \varrho_{ss} E_s = 0 \quad \text{and} \quad \frac{\delta L}{\delta \gamma} = 1 - \sum_{s=1}^{n} \varrho_{ss} = 0.$$

Hence, L is stationary under simultaneous variation of of $\{\varrho_{ss}\}_n$, β and γ if

$$\delta L = \sum_{s=1}^{n} [-(\ln \varrho_{ss} + 1) - \beta E_s - \gamma]\, \delta\varrho_{ss} = 0, \quad \sum_{s=1}^{n} \varrho_{ss} E_s = E \quad \text{and} \quad \sum_{s=1}^{n} \varrho_{ss} = 1. \qquad \square$$

F.4 Conservation of normalization and current density

The rate of change of normalization of a wave function can be written as a continuity equation

$$\frac{\partial}{\partial t} |\Psi(r,t)|^2 + \boldsymbol{\nabla} \cdot \mathbf{j} = 0, \tag{F.129}$$

which defines $\mathbf{j}$ as the probability current density of the wave function. With the time-dependent Schrödinger equation

$$i\hbar \frac{\partial}{\partial t} \Psi(r,t) = H\, \Psi(r,t) \tag{F.130a}$$

$$-i\hbar \frac{\partial}{\partial t} \Psi^*(r,t) = H\, \Psi^*(r,t) \tag{F.130b}$$

we find

$$\begin{aligned} \frac{\partial}{\partial t} |\Psi(r,t)|^2 &= \Psi^*(r,t) \frac{\partial}{\partial t} \Psi(r,t) + \Psi(r,t) \frac{\partial}{\partial t} \Psi^*(r,t) \\ &= \frac{1}{i\hbar} \left[\Psi^*(H\Psi) - \Psi(H\Psi^*) \right]. \end{aligned} \tag{F.131}$$

Hence,

$$\boldsymbol{\nabla} \cdot \mathbf{j} = \frac{i}{\hbar} \left[\Psi^*(H\Psi) - \Psi(H\Psi^*) \right]. \tag{F.132}$$

Hence, together with the continuity equation this equation shows that the normalization of a stationary state is conserved if the Hamiltonian is hermitian.

For a Hamiltonian of the type

$$H = -\frac{\hbar^2}{2m} \Delta + V(r) \tag{F.133}$$

the Eq. (F.132) takes the form

$$\boldsymbol{\nabla}\cdot\mathbf{j} = -\frac{i\hbar}{2m}\left[\psi^*(\boldsymbol{\nabla}^2\psi) - (\boldsymbol{\nabla}^2\psi^*)\psi\right] = -\frac{i\hbar}{2m}\boldsymbol{\nabla}\cdot\left[\psi^*(\boldsymbol{\nabla}\psi) - (\boldsymbol{\nabla}\psi^*)\psi\right]. \tag{F.134}$$

Hence, the continuity equation is satisfied by defining the probability current density as

$$\mathbf{j} = -\frac{i\hbar}{2m}\left(\psi^*\boldsymbol{\nabla}\psi - \psi\boldsymbol{\nabla}\psi^*\right). \tag{F.135}$$

The probability current density is a real quantity,

$$\mathbf{j} = \mathrm{Re}\left[\frac{-i\hbar}{m}\psi^*\boldsymbol{\nabla}\psi\right] = \mathrm{Re}\left[\psi^*\mathbf{v}\psi\right], \tag{F.136}$$

where $\mathbf{v} = \mathbf{p}/m = (-i\hbar/m)\,\boldsymbol{\nabla}$ is the *velocity operator*, in which we recognize the well-known *correspondence rule* $\mathbf{p} \rightarrow -\, i\hbar\boldsymbol{\nabla}$.

Writing ψ as the product of a *position-independent* amplitude $|\psi|$ and a *position-dependent* phase factor, $\psi = |\psi|e^{i\phi}$, we have

$$\mathbf{j} = \frac{i\hbar}{2m}\left(\psi\boldsymbol{\nabla}\psi^* - \psi^*\boldsymbol{\nabla}\psi\right) = \frac{i\hbar}{2m}|\psi|^2\left(e^{i\phi}\boldsymbol{\nabla}e^{-i\phi} - e^{-i\phi}\boldsymbol{\nabla}e^{i\phi}\right) = |\psi|^2\,(\hbar/m)\,\boldsymbol{\nabla}\phi. \tag{F.137}$$

Keeping in mind the flux relation $\mathbf{j} = n\mathbf{v}$, we identify $n = |\psi|^2$ as the *probability density* and

$$\mathbf{v} = (\hbar/m)\,\boldsymbol{\nabla}\phi \tag{F.138}$$

as the *probability-flow velocity.*

G

Two-level systems

G.1 Introduction

In this appendix we review the unique properties of *two-level systems.* A two-level system is a discrete quantum mechanical system with exactly two energy levels. Along with the harmonic oscillator and the Bohr atom, two-level systems belong to the select group of quantum mechanical systems for which exact analytical solutions can be obtained. The mathematical form of the solutions to be obtained in the present appendix is independent of the physical origin of the two levels. This reveals the universal properties of two-level systems. The iconic example is the electron spin in an applied magnetic field. The two-level equations are widely used in physics, be it that usually an approximation is required before they can be applied.

G.2 Two-level systems - general properties

Let us consider a closed quantum mechanical system with exactly two energy levels and described by the *time-independent* Hamiltonian $\mathcal{H}_0$. The Schrödinger equation for the eigenstates of this system,

$$\mathcal{H}_0|\phi_n\rangle = E_n^0|\phi_n\rangle, \tag{G.1}$$

defines a two-dimensional Hilbert space spanned by a basis of two state vectors, ϕ_1 and ϕ_2, corresponding to the eigenvalues E_1^0 and E_2^0, respectively. Degeneracy ($E_1^0 = E_2^0$) is not excluded. The eigenvectors can be chosen to be normalized and orthogonal and we assume this to be the case,

$$\langle\phi_n|\phi_m\rangle = \delta_{nm}, \quad \text{with} \ \ n, m \in \{1, 2\}. \tag{G.2}$$

What happens to the time evolution when we apply a perturbing field? To describe this situation we append the Hamiltonian $\mathcal{H}_0$ with a hermitian term, $\mathcal{H}_1$, representing the perturbation,

$$\mathcal{H} = \mathcal{H}_0 + \mathcal{H}_1. \tag{G.3}$$

In this context $\mathcal{H}$ is called the *full* Hamiltonian, $\mathcal{H}_0$ the *unperturbed* part and $\mathcal{H}_1$ the *perturbation.* Unlike the practice in perturbation theory the perturbation may be *strong* (i.e. dominate over $\mathcal{H}_0$) without compromising the validity of the equations. Furthermore, whereas $\mathcal{H}_0$ remains *constant* in time, the perturbation may (and often will) have an *explicit time dependence*, $\mathcal{H}_1 \to \mathcal{H}_1(t)$.

To understand how the perturbation affects the two-level system we solve the *time-dependent* Schrödinger equation

$$i\hbar\frac{\partial}{\partial t}|\psi(t)\rangle = \mathcal{H}(t)|\psi(t)\rangle \tag{G.4}$$

under the initial condition $|\psi(0)\rangle = |\psi_i\rangle$, where ψ_i is the state of the system at time $t = 0$. If $\mathcal{H}_1$ depends on time there will be energy exchange between the system and the perturbing field. There are methods to deal with this situation but these fall outside the scope of the present appendix. Leaving aside their energy, the states of the system can always be decomposed with respect to the unperturbed basis,

$$|\psi(t)\rangle = \sum_{n=1,2} |\phi_n\rangle \langle\phi_n|\psi(t)\rangle = a_1(t)|\phi_1\rangle + a_2(t)|\phi_2\rangle, \tag{G.5}$$

where the amplitudes $a_n(t) \equiv \langle\phi_n|\psi(t)\rangle$ are complex functions (depending *only on time*) and subject to the *Parseval relation*

$$|a_1(t)|^2 + |a_2(t)|^2 = 1. \tag{G.6}$$

The probability to observe the system at time $t > 0$ in the state ψ_f is given by the expression

$$W_{i\to f}(t) = |\langle\psi_f|\psi(t)\rangle|^2. \tag{G.7}$$

This is called the *transition probability* for the transition $\psi_i \to \psi_f$.

G.2.1 Solving the Schrödinger equation

To solve the Schrödinger equation we project both sides of Eq. (G.4) onto the eigenstates ϕ_n,

$$i\hbar\frac{d}{dt}a_n(t) = \langle\phi_n|\mathcal{H}_0 + \mathcal{H}_1(t)|\psi(t)\rangle, \tag{G.8}$$

with $n \in \{1, 2\}$. Substituting Eq. (G.5) into this expression and using the orthonormality relations (G.2) as well as the hermiticity of $\mathcal{H}_0$, we find that the amplitudes $a_1(t)$ and $a_2(t)$ satisfy a set of two coupled linear differential equations

$$i\hbar\frac{d}{dt}a_n(t) = E_n^0 a_n(t) + \sum_{m=1,2} \langle\phi_n|\mathcal{H}_1(t)|\phi_m\rangle a_m(t), \tag{G.9}$$

with $n \in \{1, 2\}$. Let us suppose for convenience that at $t = 0$ the system is in the eigenstate ϕ_1 (i.e., $\psi_i \to \phi_1$). In this case the initial condition for the amplitudes is

$$a_n(0) = \langle\phi_n|\psi(0)\rangle = \langle\phi_n|\phi_1\rangle = \delta_{n1}. \tag{G.10}$$

Before continuing we introduce a compact notation and derive some properties for the matrix elements:

$$H_{nm}(t) \equiv \langle\phi_n|\mathcal{H}(t)|\phi_m\rangle \quad \text{and} \quad H'_{nm}(t) \equiv \langle\phi_n|\mathcal{H}_1(t)|\phi_m\rangle, \tag{G.11}$$

with $n, m \in \{1, 2\}$. In view of the orthogonality of ϕ_1 and ϕ_2 we have

$$H_{nm}(t) = \begin{cases} H'_{nm}(t) & \text{for } n \neq m \\ E_n^0 + H'_{nn}(t) & \text{for } n = m. \end{cases} \tag{G.12}$$

Given the hermiticity of $\mathcal{H}_1$ we find[1]

$$H'_{nm} = \langle\phi_n|\mathcal{H}_1|\phi_m\rangle = \langle\phi_m|\mathcal{H}_1|\phi_n\rangle^* = H'^*_{mn}. \tag{G.13}$$

In particular, for the diagonal matrix elements this becomes

$$H'_{nn} = H'^*_{nn}, \tag{G.14}$$

showing that the diagonal elements are all *real*. In this notation the coupled equations (G.9) take the form

$$i\hbar\dot{a}_1 = H_{11}a_1 + H'_{12}a_2 \tag{G.15a}$$

$$i\hbar\dot{a}_2 = H'^*_{12}a_1 + H_{22}a_2. \tag{G.15b}$$

---

[1] From here on we mostly suppress showing the time variable in the notation.

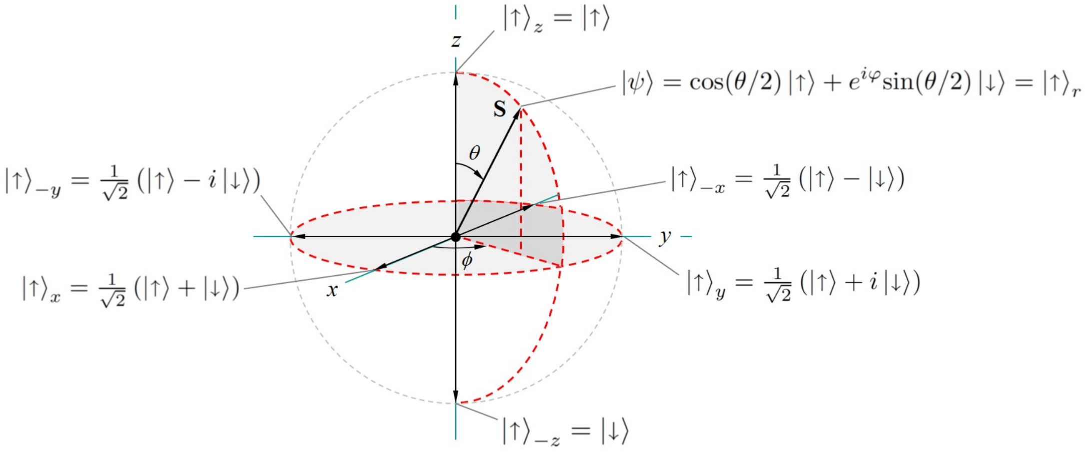

Figure G.1: A two-level system can be represented by a pseudospin **S** in 3D real space. The states of the system are defined by the angles θ and ϕ corresponding to a point on the surface of the Bloch sphere. Note that by changing the coupling angle (θ) over its range from 0 to π the mixing angle ($\alpha = \theta/2$) changes from 0 to $\pi/2$. Note further that the relative phase of the two components depends on the definition of the coordinate system (in the plot the two components are in phase in the x direction).

G.2.2 Pseudospin and Bloch sphere - formal correspondence with spin-1/2

The unique position of two-level systems among the discrete quantum systems finds its origin in the simplicity of the Parseval relation (G.6). As only two levels are involved, the occupation of one of the levels, $|a_1|^2$, fully determines that of the other, $|a_2|^2 = 1 - |a_1|^2$. This imposes a strong condition on the relation between the amplitudes a_1 and a_2. It is straightforward to show that the Parseval relation is satisfied for amplitudes of the following form:

$$a_1 = e^{-i\phi/2}\cos\alpha \quad \text{and} \quad a_2 = e^{i\phi/2}\sin\alpha. \tag{G.16}$$

In this form the quantum numbers $n \in \{1,2\}$ are replaced by two new quantities, the *mixing angle* α, with $0 \le \alpha < \pi/2$,[1] and the *relative phase* ϕ, with $0 \le \phi < 2\pi$ Actually, it is advantageous from a geometric point of view to write the mixing angle in the form

$$\alpha = \theta/2, \tag{G.17}$$

where θ is called the *coupling angle*. In Sections G.3.2 and G.3.3 we discuss why. Since θ is twice as large as α it is defined over the range $0 \le \theta < \pi$. In this notation the *states* of any two-level system are represented by two angles, θ and ϕ, which define the *polar* and *azimuthal* angle of a three-dimensional unit vector, $\hat{\mathbf{r}}$, in an *abstract real* space,

$$r_x = a_1 a_2^* + a_1^* a_2 = \sin\theta\cos\phi \tag{G.18a}$$

$$r_y = i(a_1 a_2^* - a_1^* a_2) = \sin\theta\sin\phi \tag{G.18b}$$

$$r_z = a_1 a_1^* - a_2 a_2^* = \cos\theta. \tag{G.18c}$$

Keeping in mind that a spin-$\frac{1}{2}$ system is a two-level system, Eqs. (G.18) suggest a relation between the unit vector $\hat{\mathbf{r}}$ and the direction of the magnetic moment of a spin-$\frac{1}{2}$ particle. For this reason $\hat{\mathbf{r}}$ is called the *pseudo* or *fictitious spin* of the two-level system. A first indication for the correctness of this conjecture is found by writing the decomposition for an *arbitrary* state in the form

$$|\psi\rangle = \cos(\theta/2)|\phi_1\rangle + e^{i\phi}\sin(\theta/2)|\phi_2\rangle. \tag{G.19}$$

---

[1] Any interval of $\pi/2$ could be chosen; in Section G.3.3 preference is given to $-\pi/4 \le \alpha \le \pi/4$.

In this form a_1 is chosen to be *real*, $a_1 \to \cos(\theta/2)$. This is allowed without loss of generality because we are free to choose the global phase. As is illustrated in Fig. G.1, the decomposition (G.19) relates the 2D Hilbert space of the two-level system to the surface of a sphere - the *Bloch sphere* - introduced by Felix Bloch to describe the evolution of a nuclear moment in a electromagnetic field [16]. In 1957 Richard Feynman, Frank Vernon and Robert Hellwarth showed that the evolution of *any* two-level system in a perturbing field can be mapped onto the equation of motion of a spin-$\frac{1}{2}$ system subject to a perturbation [42]. In this map the Schrödinger equation is written in the form of a real three-dimensional vector equation (see Problem G.1),

$$\frac{d\hat{\mathbf{r}}}{dt} = (\omega \times \hat{\mathbf{r}}), \tag{G.20}$$

where the components of the pseudospin $\hat{\mathbf{r}}$ uniquely refer to the state of the system and the components of the vector ω represent the perturbation,

$$\omega_x = (H'_{12} + H'^*_{12})/\hbar, \quad \omega_y = i(H'_{12} - H'^*_{12})/\hbar, \quad \omega_z = (H_{11} - H_{22})/\hbar. \tag{G.21}$$

In particular, for the magnetic interaction of a real spin-$\frac{1}{2}$ particle (e.g., electron spin) the 3D real space reduces to the physical space of observation. In optics the sphere is called the *Poincaré sphere* and the vector corresponds to an arbitrary state of polarized light (elliptical polarization). With Eqs. (G.20) and (G.21) we have obtained a universal relation for the time evolution of two-level systems.

Problem G.1. Derive the Feynman-Vernon-Hellwarth transformation by showing that the time evolution of two-level systems may be formulated in the universal form of a real three-dimensional vector equation for the pseudospin $\hat{\mathbf{r}}$,

$$\frac{d\hat{\mathbf{r}}}{dt} = (\omega \times \hat{\mathbf{r}}),$$

where the components of the $\hat{\mathbf{r}}$ uniquely refer to the state of the system and the components of the vector ω represent the perturbation.

Solution. We start by differentiating Eqs. (G.18) with respect to time,

$$\begin{aligned}
\dot{r}_x &= (\dot{a}_1 a_2^* + a_1 \dot{a}_2^* + c.c.) \\
-i\dot{r}_y &= (\dot{a}_1 a_2^* + a_1 \dot{a}_2^* - c.c.) \\
\dot{r}_z &= (\dot{a}_1 a_1^* - \dot{a}_2 a_2^* + c.c).
\end{aligned}$$

Each term in these equations follows from the Schrödinger equation using Eq. (G.15),

$$\begin{aligned}
\dot{a}_1 a_2^* &= -i(H_{11} a_1 a_2^* + H'_{12} a_2 a_2^*)/\hbar \\
a_1 \dot{a}_2^* &= i(H'_{12} a_1 a_1^* + H_{22} a_1 a_2^*)/\hbar \\
\dot{a}_1 a_1^* &= -i(H_{11} a_1 a_1^* + H'_{12} a_1^* a_2)/\hbar \\
\dot{a}_2 a_2^* &= -i(H'^*_{12} a_1 a_2^* + H_{22} a_2 a_2^*)/\hbar.
\end{aligned}$$

Then, substituting these terms and using the Parseval relation (G.6) we obtain after some rearrangement

$$\begin{aligned}
\hbar\dot{r}_x &= -i(H_{11} - H_{22})(a_1 a_2^* - a_1^* a_2) + i(H'_{12} - H'^*_{12})(a_1 a_1^* - a_2 a_2^*) \\
-i\hbar\dot{r}_y &= -i(H_{11} - H_{22})(a_1 a_2^* + a_1^* a_2) + i(H'_{12} + H'^*_{12})(a_1 a_1^* - a_2 a_2^*) \\
\hbar\dot{r}_z &= +i(H'_{12} + H'^*_{12})(a_1 a_2^* - a_1^* a_2) - i(H'_{12} - H'^*_{12})(a_1 a_2^* + a_1^* a_2).
\end{aligned}$$

Here we recognize the appearance of the components of $\hat{\mathbf{r}}$ as given in Eqs. (G.18) and write

$$\begin{aligned}
i\hbar\dot{r}_x &= -i(H_{11} - H_{22}) r_y - (H'_{12} - H'^*_{12}) r_z \\
i\hbar\dot{r}_y &= i(H_{11} - H_{22}) r_x - i(H'_{12} + H'^*_{12}) r_z \\
i\hbar\dot{r}_z &= i(H'_{12} + H'^*_{12}) r_y + (H'_{12} - H'^*_{12}) r_x.
\end{aligned}$$

In vector notation this becomes

$$\frac{d}{dt}\hat{\mathbf{r}} = -\begin{vmatrix} \hat{\mathbf{x}} & \hat{\mathbf{y}} & \hat{\mathbf{z}} \\ r_x & r_y & r_z \\ (H'_{12}+H'^{*}_{12})/\hbar & i(H'_{12}-H'^{*}_{12})/\hbar & (H_{11}-H_{22})/\hbar \end{vmatrix}.$$

This expression can be rewritten in the form of the vector equation (G.20), where the components of the vector $\boldsymbol{\omega}$ are defined in terms of the matrix elements of the Hamiltonian as given in Eq. (G.21). □

G.3 Two-level systems - static perturbations

Let us return to the coupled equations (G.15). These equations govern the evolution of two-level systems for a (generally time-dependent) Hamiltonian. They followed from the Schrödinger equation and were transformed to the vector equation (G.20) but *they were not solved.* The reason is simple: analytic solution of the differential equations is not possible for an *arbitrary* time dependence of the perturbation. This being said, analytic solutions can be given for special cases. In the present section we specialize to *static perturbations* (i.e., perturbations without an explicit time dependence). Time-dependent perturbations are not discussed in this Appendix.

Before proceeding we note that the coupled equations (G.15) can be written in the form of a matrix equation as is common practice in linear algebra,

$$i\hbar\frac{d}{dt}\begin{pmatrix} a_1 \\ a_2 \end{pmatrix} = \begin{pmatrix} H_{11} & H'_{12} \\ H'^{*}_{12} & H_{22} \end{pmatrix}\begin{pmatrix} a_1 \\ a_2 \end{pmatrix}. \tag{G.22}$$

Not surprisingly, this equation has the form of the time-dependent Schrödinger equation,

$$i\hbar\frac{d}{dt}\psi = \mathcal{H}\psi, \tag{G.23}$$

where, in matrix notation, the Hamiltonian and the state are given by

$$\mathcal{H} = \begin{pmatrix} H_{11} & H'_{12} \\ H'^{*}_{12} & H_{22} \end{pmatrix} \quad \text{and} \quad \psi = \begin{pmatrix} a_1 \\ a_2 \end{pmatrix}. \tag{G.24}$$

Specializing to the case of *static* perturbations turns $\mathcal{H}$ into an operator without an explicit time dependence. This makes it possible to integrate Eq. (G.23) by *separation of variables*,

$$\frac{1}{\psi}\frac{d\psi}{dt} = -\frac{i}{\hbar}\mathcal{H}. \tag{G.25}$$

Under the *initial condition* $\psi(0) = \psi_i$ we obtain

$$\psi(t) = e^{-(i/\hbar)\mathcal{H}t}\psi_i. \tag{G.26}$$

Note the appearance of the evolution operator. If ψ_i is an *eigenstate* of $\mathcal{H}$ (corresponding to the eigenvalue E_i) it satisfies the Schrödinger equation

$$\mathcal{H}\psi_i = E_i\psi_i, \tag{G.27}$$

and the evolution becomes stationary; i.e., there is only evolution of the *global* phase,

$$|\psi(t)\rangle = e^{-(i/\hbar)E_i t}|\psi_i\rangle. \tag{G.28}$$

The exponential prefactor is called the *dynamical phase* of the state.

In cases where ψ_i is *not* an eigenstate of $\mathcal{H}$ the time evolution is not stationary. Non-stationary evolution under *static* perturbations is the subject of Section G.4

G.3.1 Level shifts and mixing of the eigenstates

As is well known from linear algebra Eq. (G.27) represents an eigenvalue problem. Non-singular solutions exist if and only if the *characteristic determinant*, traditionally referred to as the *secular determinant*,[1] is zero,

$$\begin{vmatrix} H_{11}-E & H'_{12} \\ H'^{*}_{12} & H_{22}-E \end{vmatrix} = 0. \tag{G.29}$$

Eq. (G.29) is known as the *characteristic equation* (*secular equation*) of the problem. By solving this equation we find the eigenvalues of $\mathcal{H}$. As is evident from Eq. (G.29), for two-level systems the characteristic equation takes the form of a quadratic equation in E,

$$(H_{11}-E)(H_{22}-E) = |H'_{12}|^2 . \tag{G.30}$$

The eigenvalues are given by the roots of this equation.

- In the *absence of mixing* of the eigenstates ($H'_{12}=0$) the Hamiltonian is *diagonal* and we easily find $E_+ = H_{11}$ and $E_- = H_{22}$. Furthermore, we are free (without loss of generality) to choose the state labeling such that

  $$H_{11} \geq H_{22}. \tag{G.31}$$

  In this convention E_+ and E_- correspond to the upper and lower level, respectively ($E_+ \geq E_-$).

- Also in the *presence of mixing* ($H'_{12} \neq 0$) we have $E_+ > E_-$ under the convention (G.31) because the *off-diagonal* matrix elements always result in *level repulsion* (see Section G.3.2). The *general solution* of the quadratic equation is given by the "square root formula",

  $$E_{\pm} = \tfrac{1}{2}(H_{11}+H_{22}) \pm \tfrac{1}{2}\sqrt{(H_{11}-H_{22})^2 + 4|H'_{12}|^2}. \tag{G.32}$$

  Note that the discriminant is always positive or zero; i.e., the eigenvalues are real as required for the eigenvalues of a hermitian operator.

G.3.2 Eigenvalues and coupling angle

To study the effect of the perturbation we introduce the *coupling angle* θ and its tangent

$$\tan\theta \equiv \frac{2|H'_{12}|}{H_{11}-H_{22}}, \tag{G.33}$$

where θ is defined on the interval $-\pi/2 \leq \theta \leq \pi/2$ (under the convention (G.31) this is the interval $0 \leq \theta \leq \pi/2$). The name *coupling angle* refers to the coupling of the two differential equations in Eqs. (G.15) by the off-diagonal matrix elements H'_{12} and H'^{*}_{12}. In Section G.3.3 this coupling angle will be identified with the coupling angle introduced in Section G.2.2. We distinguish between *weak* and *strong* coupling (cf. Section G.3.4):

- The coupling is called *weak* if the off-diagonal matrix elements are "smaller than the level splitting", $|H'_{12}| \ll |H_{11}-H_{22}|$. In this case the coupling angle is *small* ($0 \leq \tan^2\theta \ll 1$).
- Likewise, the coupling is called *strong* for $|H'_{12}| \gg |H_{11}-H_{22}|$. In this case the coupling angle is *large*; i.e., close to $\pm\pi/2$ ($0 \leq \cot^2\theta \ll 1$). Note that in the *absence of asymmetry* ($H_{11} = H_{22}$) *any* coupling is strong.

---

[1] The adjective secular was introduced in astronomy to describe non-cyclic variations in the planetary motion caused by the interactions between planets.

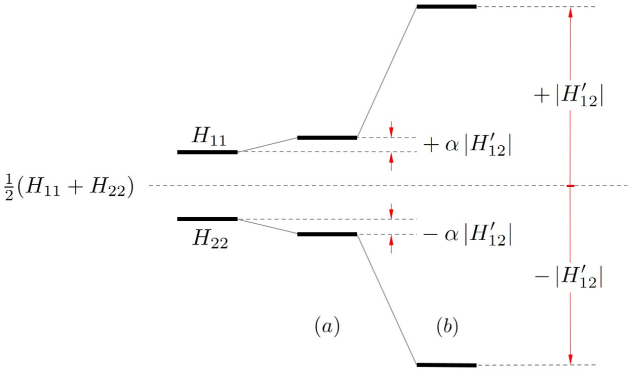

Figure G.2: Level shifts in two-level systems are symmetric with respect to the average value of the *diagonal* matrix elements, $\frac{1}{2}(H_{11}+H_{22})$: (a) *weak* repulsion by an *off-diagonal* matrix element ($|H'_{12}| \ll H_{11}-H_{22}$); (b) *strong* repulsion by an *off-diagonal* matrix element ($H_{11}-H_{22} \ll |H'_{12}|$).

Let us have a closer look at Eq. (G.32). Using the coupling angle this equation can be rewritten in one of the two following equivalent forms

$$E_{\pm} = \tfrac{1}{2}(H_{11}+H_{22}) \pm \tfrac{1}{2}(H_{11}-H_{22})\sqrt{1+\tan^2\theta} \tag{G.34a}$$

$$E_{\pm} = \tfrac{1}{2}(H_{11}+H_{22}) \pm |H'_{12}|\,\sqrt{1+\cot^2\theta}, \tag{G.34b}$$

where the labeling of the energy levels is chosen in accordance with the convention (G.31); i.e., $E_+ \to H_{11}$ and $E_- \to H_{22}$ in the limit of weak coupling ($\theta \to 0$). Note that there is no ambiguity in the sign of the square root,

$$\sqrt{1+\tan^2\theta} = 1/\cos\theta > 1 \quad \text{for} \quad -\pi/2 \le \theta \le \pi/2. \tag{G.35}$$

Also the level splitting $\Delta E = E_+ - E_-$ follows directly from Eq. (G.32),

$$\Delta E = \sqrt{(H_{11}-H_{22})^2 + 4\,|H'_{12}|^2}. \tag{G.36}$$

In terms of the coupling angle this becomes

$$\Delta E = \tfrac{1}{2}(H_{11}-H_{22})\sqrt{1+\tan^2\theta} \tag{G.37a}$$

$$\Delta E = 2\,|H'_{12}|\,\sqrt{1+\cot^2\theta}. \tag{G.37b}$$

The upper form of Eqs. (G.34) and (G.37) is best suited to analyze weak coupling ($\tan^2\theta \ll 1$); the lower form for strong coupling ($\cot^2\theta \ll 1$). The expressions shows that for weak coupling the splitting is dominated by the diagonal matrix elements whereas for strong coupling it is a direct measure of the coupling strength - see Fig. G.2.

Level repulsion

Note that the coupling gives rise to a shift of the energy levels which is symmetric about the average value $\frac{1}{2}(H_{11}+H_{22})$. More precisely, under the convention (G.31) the levels *repel* each other [119]. This is illustrated in Fig. G.2 for the degenerate case. The repulsion is easily verified by rewriting Eq. (G.34a) in the form

$$E_+ = H_{11} + \tfrac{1}{2}(H_{11}-H_{22})(\sqrt{1+\tan^2\theta}-1) \tag{G.38a}$$

$$E_- = H_{22} - \tfrac{1}{2}(H_{11}-H_{22})(\sqrt{1+\tan^2\theta}-1). \tag{G.38b}$$

The average value $\frac{1}{2}(H_{11}+H_{22})$ may be chosen as the zero of energy for most practical purposes.

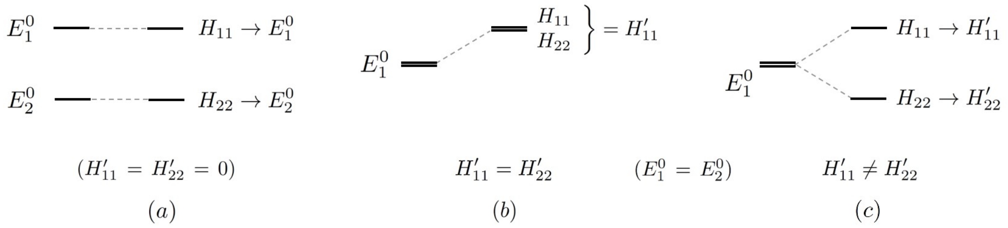

Figure G.3: Three special cases: (a) *absence* of diagonal shifts; (b) *degeneracy* with *symmetric* diagonal shift; (c) *degeneracy* with *asymmetric* diagonal shift.

Special cases

When dealing with energy levels and shifts induced by the perturbation it is good to mention a few special cases in which the equations simplify.

- *zero diagonal shift* $(H'_{11} = H'_{22} = 0)$: in this case the diagonal matrix elements of the *full* Hamiltonian coincide with those of $\mathcal{H}_0$ - see Fig. G.3a

$$H_{11} \to E_1^0 \quad \text{and} \quad H_{22} \to E_2^0. \tag{G.39}$$

- *degeneracy* of the unperturbed levels $(E_1^0 = E_2^0)$: in this case the diagonal matrix elements of the *full* Hamiltonian coincide with those of the perturbation,

$$H_{11} \to H'_{11} \quad \text{and} \quad H_{22} \to H'_{22}. \tag{G.40}$$

  We distinguish between two cases: (a) *symmetric* diagonal shifts $(H'_{11} = H'_{22})$; (b) *asymmetric* diagonal shifts $(H'_{11} \neq H'_{22})$ - see Fig. G.3*b,c.*

- *zero off-diagonal shift* $(H'_{12} = H'_{21} = 0)$: in this case there is no coupling between the levels although the levels shift as a result of the diagonal matrix elements of the perturbation,

$$E_\pm = \tfrac{1}{2}(H_{11} + H_{22}) \pm \tfrac{1}{2}(H_{11} - H_{22}) = \begin{cases} H_{11} \\ H_{22} \end{cases}. \tag{G.41}$$

G.3.3 Eigenstates

Ones we have the eigenvalues $E_\pm$ we obtain the corresponding eigenstates $\psi_\pm$ by substituting the eigenvalues into the Schrödinger equation. In matrix notation this becomes

$$\begin{pmatrix} H_{11} & H'_{12} \\ H'^{*}_{12} & H_{22} \end{pmatrix} \begin{pmatrix} A_\pm \\ B_\pm \end{pmatrix} = E_\pm \begin{pmatrix} A_\pm \\ B_\pm \end{pmatrix}, \quad \text{with} \quad \psi_\pm \equiv \begin{pmatrix} A_\pm \\ B_\pm \end{pmatrix}. \tag{G.42}$$

As we recall from Section G.2.2, the eigenstates of a two-level system are fully defined by the mixing angle and the relative phase - see Eq. (G.16). In Problem G.2 we show that in terms of these angles the amplitudes of the eigenstates are given by

$$a_1 \to \begin{cases} A_+ = +e^{-i\phi/2}\cos\alpha \\ A_- = -e^{-i\phi/2}\sin\alpha \end{cases} \quad \text{and} \quad a_2 \to \begin{cases} B_+ = e^{i\phi/2}\sin\alpha = -A_- e^{i\phi} \\ B_- = e^{i\phi/2}\cos\alpha = A_+ e^{i\phi} \end{cases}. \tag{G.43}$$

In this format the eigenstates become (in Dirac notation)

$$|\psi_+\rangle = +e^{-i\phi/2}\cos\alpha|\phi_1\rangle + e^{i\phi/2}\sin\alpha|\phi_2\rangle \tag{G.44a}$$

$$|\psi_-\rangle = -\mathrm{e}^{-\mathrm{i}\phi/2}\sin\alpha|\phi_1\rangle + e^{i\phi/2}\cos\alpha|\phi_2\rangle. \tag{G.44b}$$

As expected for a basis transformation Eqs. (G.44) define a unitary transformation between the eigenstates of $\mathcal{H}$ and those of $\mathcal{H}_0$ (cf. Problem 3.20). Importantly, as the *probabilities of occupation*,

$$|B_-|^2 = |A_+|^2 = \cos^2\alpha \quad \text{and} \quad |B_+|^2 = |A_-|^2 = \sin^2\alpha, \tag{G.45}$$

are independent of the phase we are free to choose the coordinate system such that the relative phase vanishes, $\phi = 0$. In this convention the amplitudes are *real* quantities and related by

$$B_+ = -A_- \quad \text{and} \quad B_- = A_+. \tag{G.46}$$

So the eigenstates of $\mathcal{H}$ take the convenient form

$$|\psi_+\rangle = +\cos\alpha|\phi_1\rangle + \sin\alpha|\phi_2\rangle \tag{G.47a}$$

$$|\psi_-\rangle = -\sin\alpha|\phi_1\rangle + \cos\alpha|\phi_2\rangle. \tag{G.47b}$$

The inverse transformation is given by

$$|\phi_1\rangle = \cos\alpha|\psi_+\rangle - \sin\alpha|\psi_-\rangle \tag{G.48a}$$

$$|\phi_2\rangle = \sin\alpha|\psi_+\rangle + \cos\alpha|\psi_-\rangle. \tag{G.48b}$$

What remains to be done is demonstrate that the coupling angle defined in Eq. (G.33) coincides with the coupling angle introduced for the pseudospin in Eq. (G.17). This follows in a few steps from Eqs (G.45). First we notice that $\tan^2\alpha$ may be expressed as

$$\tan^2\alpha = |B_+/A_+|^2 = |A_-/A_+|^2. \tag{G.49}$$

Substituting E_+ from Eq. (G.38a) into the Eq. (G.42) we obtain under the convention (G.31) [1]

$$\tan^2\alpha = \frac{(E_+ - H_{11})^2}{|H'_{12}|^2} = \frac{(\sqrt{1+\tan^2\theta}-1)^2}{\tan^2\theta} = \frac{(1-\cos\theta)^2}{\sin^2\theta} = \frac{1-\cos\theta}{1+\cos\theta} = \tan^2(\theta/2). \tag{G.50}$$

Here we used Eq. (G.35) as well as the double-angle formulas for the cosine. With this result we established that the mixing angle α, introduced in Eq. (G.33), can be identified with *half* the coupling angle as defined in Eq. (G.33), $\alpha = \theta/2$. Since θ is defined over a range of π on the interval $-\pi/2 < \theta \le \pi/2$, the mixing angle is restricted to a range of $\pi/2$ on the interval $-\pi/4 < \alpha \le \pi/4$.[2] Alternatively, we can use the periodicity of $\tan\theta$ to redefine θ on the interval $0 \le \theta < \pi$ (i.e., α restricted to the interval $0 \le \alpha < \pi/2$). The latter convention was used to map the states of a pseudospin onto the Bloch sphere (see Section G.2.2).

An expression for the coupling coefficient $|A_+|^2$ in terms of the matrix elements is obtained using the trigonometric relation between $\cos^2\alpha$ and $\tan^2\alpha$,

$$|A_+|^2 = \cos^2\alpha = \frac{1}{1+\tan^2\alpha} = \frac{|H'_{12}|^2}{(E_+ - H_{11})^2 + |H'_{12}|^2}. \tag{G.51}$$

A nice consequence of the convention $-\pi/4 \le \alpha \le \pi/4$ is the inequality $\cos^2\alpha \ge \sin^2\alpha$. Note that this can serve as a convenient pointer to the dominant component of a mixed state (e.g., see the figures of magnetic fine- and hyperfine structure in Chapters 4 and 5).

---

[1] By substituting the solution (G.38b) into Eq. (G.42) we obtain the same result.

[2] Adopting the convention (G.31) we can restrict the angles to positive values, $0 \le \theta \le \pi/2$ and $0 \le \alpha \le \pi/4$.

Problem G.2. Derive Eqs. (G.43).

Solution. Introducing for the eigenstates $\psi_\pm$ the mixing angles $\alpha_\pm$ and phase angles $\theta_\pm$ we have in the notation of Section G.2.2

$$a_1 \to A_\pm = e^{-i\phi_\pm/2}\cos\alpha_\pm \quad \text{and} \quad a_2 \to B_\pm = e^{i\phi_\pm/2}\sin\alpha_\pm .$$

Since the eigenstates have to be orthogonal we require $\langle\psi_+|\psi_-\rangle = A_+^* A_- + B_+^* B_- = 0$. In terms of the angles this condition becomes

$$e^{i(\phi_+-\phi_-)/2}\cos\alpha_+\cos\alpha_- + e^{-i(\phi_+-\phi_-)/2}\sin\alpha_+\sin\alpha_- = 0.$$

This condition is satisfied for $\cos\alpha_- = -\sin\alpha_+$ and $\sin\alpha_- = \cos\alpha_+$ in combination with

$$e^{i(\phi_+-\phi_-)/2} - e^{-i(\phi_+-\phi_-)/2} = -2i\sin[(\phi_+ - \phi_-)/2] = 0.$$

In term of the angles this is satisfied for $\alpha_- = \alpha_+ + \pi/2$ and $\phi_- = \phi_+$. Changing notation $\alpha_+ \to \alpha$ and $\phi_+ \to \phi$ this results in the requested expressions. □

G.3.4 Weak versus strong coupling

In Section G.3.2 we introduced the concepts of weak and strong coupling by comparing the strength of the off-diagonal matrix elements, $|H'_{12}|$, with the difference of the diagonal ones, $H_{11} - H_{22}$, under the convention (G.31). We now analyze these cases in more detail using Fig. G.2 for purposes of illustration:

- *Weak coupling (strong asymmetry),* $|H'_{12}|^2 \ll (H_{11} - H_{22})^2 \to \alpha^2 \simeq \frac{1}{4}\tan^2\theta \ll 1$. In this regime Eq. (G.34a) reduces to

  $$E_+ = H_{11} + \alpha^2 (H_{11} - H_{22}) + \cdots = H_{11} + \alpha\,|H'_{12}| + \cdots , \tag{G.52a}$$

  $$E_- = H_{22} - \alpha^2 (H_{11} - H_{22}) + \cdots = H_{22} - \alpha\,|H'_{12}| + \cdots . \tag{G.52b}$$

  Here we used the expansion $\sqrt{1+\tan^2\theta} = 1 + \frac{1}{2}\tan^2\theta + \cdots = 1 + 2\alpha^2 + \cdots$. Note that the contribution of the off-diagonal matrix elements $|H'_{12}|$ is suppressed by a factor α with respect to the diagonal ones, H_{11} and H_{22}. In other words, the *diagonal elements contribute in first order*, cf. Eq. (H.56), whereas the *off-diagonal elements contribute in second-order*, cf. Eq. (H.63). The corresponding basis coefficients satisfy the relations

  $$A_\pm|^2 = \begin{cases} \cos^2\alpha & = 1 - \alpha^2 + \cdots \\ \sin^2\alpha & = \alpha^2 + \cdots . \end{cases} \tag{G.53}$$

  In the limit $|H'_{12}| \to 0$ we obtain the case of *no coupling* (zero off-diagonal shift), in which

  $$E_+ = H'_{11} \text{ and } E_- = H_{22}, \text{ with } |A_+|^2 = 1 \text{ and } |A_-|^2 = 0. \tag{G.54}$$

- *Strong coupling (weak asymmetry),* $(H_{11} - H_{22})^2 \ll |H'_{12}|^2 \Leftrightarrow \cot^2\theta \ll 1$. In this case Eq. (G.34b) reduces to

  $$E_\pm = \tfrac{1}{2}(H_{11} + H_{22}) \pm |H'_{12}|\,(1 + \tfrac{1}{2}\cot^2\theta + \cdots). \tag{G.55}$$

  Here we used the expansion $\sqrt{1+\cot^2\theta} = 1 + \frac{1}{2}\cot^2\theta + \cdots$. In this limit the mixing coefficients satisfy the relations

  $$A_\pm^2 = \tfrac{1}{2}(1 \pm \cot^2\theta + \cdots). \tag{G.56}$$

  In the limit $H_{11} \to H_{22}$ we obtain the *symmetric case*, in which

  $$E_\pm = H_{11} \pm |H'_{12}| \text{ and } A_\pm^2 = \tfrac{1}{2}. \tag{G.57}$$

- *Crossover regime.* In case we are neither weakly nor strongly coupled we are dealing with crossover behavior between the two limits. In this case the shifts cannot be approximated and we have to apply the exact expression; i.e., Eq. (G.32).

G.4 Non-stationary evolution under a static perturbation

Let us return to the time-dependent aspects of the two-level system. We start by assuming that the system is at time $t = 0$ in the eigenstate ϕ_1 of the unperturbed Hamiltonian, $\mathcal{H}_0$. To find the time evolution under the *full* Hamiltonian we solve the time-dependent Schrödinger equation

$$i\hbar\frac{\partial}{\partial t}|\psi(t)\rangle = \mathcal{H}|\psi(t)\rangle \tag{G.58}$$

under the initial condition $|\psi(0)\rangle \equiv |\phi_1\rangle$. For a static perturbation, i.e., a perturbation without explicit time dependence, the full Hamiltonian is also independent of time and along the lines of Section G.3 we obtain for the time evolution of the initial state ϕ_1

$$|\psi(t)\rangle = e^{-(i/\hbar)\mathcal{H}t}|\phi_1\rangle. \tag{G.59}$$

In the absence of the perturbation, $\mathcal{H}_0 = 0$, the system remains in the state ϕ_1. This is the stationary evolution of Section G.3. In the present section we discuss how the state evolves for a non-vanishing static perturbation. In particular we are interested in finding out how the perturbation gives rise to a probability of observing the system at $t > 0$ in the eigenstate ϕ_2. As discussed in the introduction of Section G.2 this means that we are looking for the *transition probability*

$$W_{1\to 2}(t) = |\langle\phi_2|\psi(t)\rangle|^2. \tag{G.60}$$

G.4.1 Special case

To introduce the subject we start with a special case. We consider the full Hamiltonian $\mathcal{H}$ with eigenvalues E_+ and E_- and suppose for convenience that the corresponding eigenstates ψ_+ and ψ_- are given by symmetric (+) and anti-symmetric (−) linear combinations of the eigenstates of $\mathcal{H}_0$),

$$|\psi_+\rangle = \sqrt{1/2}\,(|\phi_1\rangle + |\phi_2\rangle) \tag{G.61a}$$

$$|\psi_-\rangle = \sqrt{1/2}\,(|\phi_1\rangle - |\phi_2\rangle)\,. \tag{G.61b}$$

Note that this is a special case of Eqs. (G.47a) with $\sin^2\alpha = \cos^2\alpha = \frac{1}{2}$. This is called a 50/50 *coherent* mixture of the eigenstates ϕ_1 and ϕ_2 corresponding to a mixing angle of $\alpha = \pi/4$ and coupling angle $\theta = \pi/2$ ($\cot^2\theta \to 0$). Adding Eqs. (G.61) and solving for $|\phi_1\rangle$ (the initial state) we find

$$|\phi_1\rangle = \sqrt{1/2}\,(|\psi_+\rangle + |\psi_-\rangle)\,. \tag{G.62}$$

Next we substitute this expression into the time-dependent solution (G.59),

$$|\psi(t)\rangle = \sqrt{1/2}\left[e^{-(i/\hbar)E_+t}|\psi_+\rangle + e^{-(i/\hbar)E_-t}|\psi_-\rangle\right], \tag{G.63}$$

and project the result on the eigenstate ϕ_2. Using the orthonormality of the ϕ_1 and ϕ_2 as well as the decompositions (G.61) this leads to the *amplitude* for observing the system at time $t > 0$ in "level 2" (i.e., in the eigenstate ϕ_2),

$$a_2(t) = \tfrac{1}{2}e^{-(i/\hbar)E_+t}\left[1 - e^{(i/\hbar)(E_+-E_-)t}\right]. \tag{G.64}$$

Introducing the angular frequency

$$\omega = (E_+ - E_-)/\hbar \tag{G.65}$$

the *probability* for observing the system in level 2 becomes

$$W_{1\to 2}(t) = \tfrac{1}{4}\left[2 - e^{i\omega t} - e^{-i\omega t}\right] = \tfrac{1}{2}(1 - \cos\omega t) = \sin^2\tfrac{1}{2}\omega t. \tag{G.66}$$

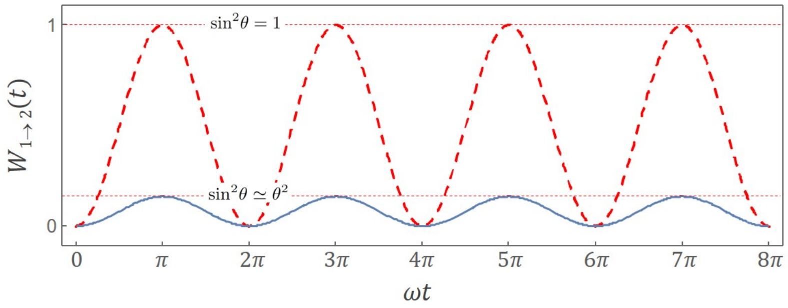

Figure G.4: Transition probability from level 1 to level 2 as a function of time after switching on a perturbation. Full transfer of the population can be achieved for the coupling angle $\theta = \pm\pi/2$ (dashed red line). In the limit of weak coupling ($\theta \ll 1$) the transfer efficiency is at best $\sin^2\theta \simeq \theta^2$ (solid blue line).

This result is plotted as the dashed red line in Fig. G.4. Note that at $t = 0$ the probability to observe the system in level 2 is zero, in accordance with the initial condition $|\psi(0)\rangle \equiv |\phi_1\rangle$. With increasing time the transition probability grows until at $\omega t = \pi$ the system is with unit probability in level 2. Continuing, the probability oscillates in time between zero and one at angular frequency ω. This has an important consequence. By applying the perturbation at $t = 0$ for the duration $\Delta t = \pi/\omega_0$ (better: $\Delta t = (\pi \pm 2n\pi)/\omega$, with $n = 0, \pm 1, \pm 2, \cdots$) we can transfer the entire population of a two-level system from level 1 to level 2. Such a timed pulse is called a *Rabi pulse* (better: a *zero-frequency* Rabi pulse). Since for the 50/50 mixture the coupling angle is $\theta = \pi/2$ ($\cot^2\theta \to 0$) we find for the angular frequency - see Eqs. (G.34b)

$$\omega = \frac{2}{\hbar}\,|H'_{12}|\,\sqrt{1+\cot^2\theta} \to \frac{2}{\hbar}\,|H'_{12}| \quad \text{for} \;\; \theta \to \pi/2. \tag{G.67}$$

G.4.2 The general case - Rabi's formula

It is straightforward to generalize the example of the previous section to cases with an arbitrary mixing angle. For this purpose we recall Eqs. (G.47),

$$|\psi_+\rangle = +\cos\alpha|\phi_1\rangle + \sin\alpha|\phi_2\rangle \tag{G.68a}$$

$$|\psi_-\rangle = -\sin\alpha|\phi_1\rangle + \cos\alpha|\phi_2\rangle \tag{G.68b}$$

and its inverse, Eqs. (G.48). Sticking to the same initial condition as before the decomposition of the initial state is given by

$$|\psi(0)\rangle = |\phi_1\rangle = \cos\alpha|\psi_+\rangle - \sin\alpha|\psi_-\rangle. \tag{G.69}$$

Using Eq. (G.59) we find for the time evolution

$$\langle\phi_2|\psi(t)\rangle = \sin\alpha\cos\alpha\left[e^{-(i/\hbar)E_+t} - e^{-(i/\hbar)E_-t}\right]. \tag{G.70}$$

In terms of the angular frequency (G.65) the *probability* to observe the system at time t in level 2 is given by

$$W_{1\to 2}(t) = 4\sin^2\!\alpha\cos^2\!\alpha\sin^2\tfrac{1}{2}\omega t. \tag{G.71}$$

In terms of the coupling angle this further simplifies to the form of *Rabi's formula* [85],

$$W_{1\to 2}(t) = \sin^2\!\theta\sin^2\tfrac{1}{2}\omega t. \tag{G.72}$$

Just as in the previous section, the probability oscillates at angular frequency ω. The difference is in coupling strength. For *strong* coupling, $\cot^2\theta \to 0$ $(\theta \to \pi/2)$, we regain Eq. (G.66). The transition probability oscillates between zero and one. On the other hand, for *weak* coupling, $\tan^2\theta \to 0$, the transition probability oscillates between zero and the small value $\sin^2\theta$. In other words, aside from oscillating in time, the transition probability increases with the strength of the coupling until it saturates because a probability cannot become larger than one. This conclusion is satisfactory, also from the intuitive point of view. Using the trigonometric relation $\sin^2\theta = \tan^2\theta/(1+\tan^2\theta)$ we find by substitution of Eq. (G.33)

$$\sin^2\theta = \frac{4(H_{11}-H_{22})^2}{(H_{11}-H_{22})^2 + 4\left|H'_{12}\right|^2}. \tag{G.73}$$

For the level splitting we find

$$\omega = 2\left|H'_{12}\right|/\hbar \quad (\cot^2\theta \to 0); \qquad \omega = (H_{11}-H_{22})/\hbar \quad (\tan^2\theta \to 0). \tag{G.74}$$

Note that for $\cot^2\theta \to 0$ $(\theta \to \pi/2)$ we regain Eq. (G.66). In the absence of a diagonal shift $(H'_{11} = H'_{22} = 0)$ the angular frequency approaches in the limit of weak coupling $(\tan^2\theta \to 0)$ the transition frequency of the unperturbed system.

$$\omega_0 \equiv (E_2^0 - E_1^0)/\hbar. \tag{G.75}$$

In atomic physics this quantity is known as the *Bohr frequency.* In Fig. G.4 we show the transition probability (G.72) for transitions from level 1 to level 2 as a function of time for both *strong* $(\cot^2\theta \to 0$ - dashed red line) and *weak* coupling $(\tan^2\theta \to 0$ - solid blue line).

H

Time-independent perturbation theory

H.1 Introduction

In most cases of practical importance physical systems cannot be studied without approximation and quantum mechanical systems are no exception to this rule. Unfortunately, exact solutions of the Schrödinger equation can only be obtained for a hand full of simple systems. Therefore, methods of approximation play a crucial role in the application of quantum mechanics. Obviously, in the computer era with massive calculational power at our disposal, approximate solutions of high precision are available using numerical methods. However, these methods constitute a field in itself and are better introduced in the context of mathematics. In this course we follow the tradition of focusing on analytical approaches as these offer structured insight in the physics of the quantum mechanical system under consideration. Importantly, although the approximate methods to be discussed are often intuitively convincing and appealing one should be aware that their foundation is generally non-trivial and forms an important subject of mathematical physics.[1] In this appendix we discuss analytical approximations for *time-independent* phenomena in systems with *discrete energy levels* resulting from a *time-independent* Hamiltonian. Time-dependent phenomena form a topic in itself and are best discussed separately.

In *time-independent* perturbation theory we consider physical systems in which the eigenstates and eigenvalues of the Hamiltonian $\mathcal{H}$ of the system are known, except for the effects of a *small* and *stationary* perturbing term $\mathcal{H}_1$. Typically this gives rise to level shifts and/or level splittings. To develop the theory the Hamiltonian $\mathcal{H}$ is broken up in two hermitian parts,

$$\mathcal{H} = \mathcal{H}_0 + \mathcal{H}_1, \tag{H.1}$$

where $\mathcal{H}_0$ is called the *unperturbed part* and $\mathcal{H}_1$ the *perturbation.* We shall consider systems where the Schrödinger equation for the unperturbed Hamiltonian

$$\mathcal{H}_0 \left|\phi_n\right\rangle = E_n^0 \left|\phi_n\right\rangle . \tag{H.2}$$

defines a *discrete* set of (known) eigenvalues $\{E_n^0\}$ corresponding to an *orthonormal* set of (known) eigenstates $\{|\phi_n\rangle\}$, for instance corresponding to the *bound states* of a system. The presence of an additional continuum of states is not considered here but can be included in the closure of the Hilbert space. The Schrödinger equation for the full Hamiltonian

$$\mathcal{H}|\psi_n\rangle = E_n|\psi_n\rangle \tag{H.3}$$

defines a discrete set of (unknown) eigenvalues $\{E_n\}$ corresponding to an orthonormal set of (unknown) eigenstates $\{|\psi_n\rangle\}$. Because the perturbation is small we expect only a small shift of the

---

energy level E_n with respect to the value E_n^0. Projecting both sides of the Schrödinger equation (H.3) on an arbitrary unperturbed state $|\phi_\nu\rangle$ we obtain, after splitting off the perturbation and using the hermiticity of $\mathcal{H}_0$,

$$E_n\langle\phi_\nu|\psi_n\rangle = \langle\phi_\nu|\mathcal{H}_0 + \mathcal{H}_1|\psi_n\rangle = E_\nu^0\langle\phi_\nu|\psi_n\rangle + \langle\phi_\nu|\mathcal{H}_1|\psi_n\rangle. \tag{H.4}$$

Thus we found a set of expressions relating the energy of the perturbed level E_n with the energies E_ν^0 of all the eigenstates $\{|\phi_n\rangle\}$ of the unperturbed Hamiltonian $\mathcal{H}_0$,

$$E_n = E_\nu^0 + \frac{\langle\phi_\nu|\mathcal{H}_1|\psi_n\rangle}{\langle\phi_\nu|\psi_n\rangle}. \tag{H.5}$$

For the special case $\nu = n$ this relation corresponds to an expression for the energy shift,

$$\Delta E_n = E_n - E_n^0 = \frac{\langle\phi_n|\mathcal{H}_1|\psi_n\rangle}{\langle\phi_n|\psi_n\rangle}. \tag{H.6}$$

It will be our approach to derive an approximate solution for the level shift with a method of successive approximation starting from Eq. (H.6). This method is called *Rayleigh-Schrödinger perturbation theory* Schrödinger [99]. We distinguish between perturbation theory for non-degenerate levels (*ordinary* perturbation theory - see Section H.2) and that for degenerate levels (see Section H.3). It will be shown that the ordinary theory embodies a method of successive approximation describing the level shift (H.6); for the degenerate case the method amounts to the diagonalization of the degenerate subspace and describes the lifting of degeneracy by splitting into nondegenerate sublevels.

H.2 Perturbation theory for non-degenerate levels

We start with the case of a *non-degenerate* energy level E_n. To develop the perturbation theory we introduce a parameterized Hamiltonian

$$\mathcal{H}(\lambda) = \mathcal{H}_0 + \lambda\mathcal{H}_1, \tag{H.7}$$

with a set of (unknown) orthonormal eigenstates $\{|\psi_n(\lambda)\rangle\}$ satisfying the Schrödinger equation

$$\mathcal{H}(\lambda)\,|\psi_n(\lambda)\rangle = E_n(\lambda)\,|\psi_n(\lambda)\rangle\,. \tag{H.8}$$

The parameter λ enables us to vary the strength of the perturbation and is introduced solely to keep track of the order at which the perturbation contributes; for $\lambda \to 0$ the $\mathcal{H}(\lambda)$ reduces to the unperturbed Hamiltonian, $\lim_{\lambda\to 0}\mathcal{H}(\lambda) = \mathcal{H}_0$; for $\lambda \to 1$ we obtain the full Hamiltonian, $\lim_{\lambda\to 1}\mathcal{H}(\lambda) = \mathcal{H}_0 + \mathcal{H}_1$. Using the Hamiltonian (H.7) the expression (H.5) changes into

$$E_n(\lambda) = E_\nu^0 + \lambda\frac{\langle\phi_\nu|\mathcal{H}_1\,|\psi_n(\lambda)\rangle}{\langle\phi_\nu|\psi_n(\lambda)\rangle}. \tag{H.9}$$

The denominator of the second term plays an important role in the perturbation theory and will be denoted by

$$a_\nu(\lambda) \equiv \langle\phi_\nu|\psi_n(\lambda)\rangle. \tag{H.10}$$

Eq. (H.9) is the starting point to obtain approximate solutions for the levels $E_n(\lambda)$ and the coefficients $a_\nu(\lambda)$. This is done with an iterative procedure in which Eq. (H.9) is expressed in the form of an hierarchy of equations of increasing power of λ obtained from the Ansatz

$$|\psi_n(\lambda)\rangle \equiv |\phi_n\rangle + \lambda|\psi_n^1\rangle + \lambda^2|\psi_n^2\rangle + \cdots\,, \tag{H.11}$$

where $|\psi_n^p\rangle$ corresponds to the pth-order correction to the wavefunction, with $p \in \{0, 1, \cdots\}$ and $|\psi_n^0\rangle \equiv |\phi_n\rangle$. As will be shown below the corrections $|\psi_n^p\rangle$ can be chosen orthogonal to the unperturbed state, $\langle\phi_n|\psi_n^p\rangle = 0$, and we will do so in a later stage. The Ansatz (H.11) implies an expansion in powers of λ for the function $a_\nu(\lambda)$,

$$a_\nu(\lambda) = \langle\phi_\nu|\psi_n(\lambda)\rangle = \delta_{\nu n} + \lambda a_\nu^{(1)} + \lambda^2 a_\nu^{(2)} + \cdots, \tag{H.12}$$

where the coefficients are defined by $a_\nu^{(p)} = \langle\phi_\nu|\psi_n^p\rangle$. For weak perturbations the Ansatz assures that the coefficients $a_\nu(\lambda)$ will change regularly with λ over the full interval $0 \leq \lambda \leq 1$ (in particular at the end points) and differ little, $a_\nu(\lambda) - a_\nu^{(0)} \ll 1$, from the unperturbed value $a_\nu^{(0)}$ given by

$$a_\nu^{(0)} \equiv \lim_{\lambda\to 0} a_\nu(\lambda) = \lim_{\lambda\to 0} \langle\phi_\nu|\psi_n(\lambda)\rangle = \langle\phi_\nu|\phi_n\rangle = \delta_{\nu n}. \tag{H.13}$$

The norm of the parameterized wavefunction is given by

$$\langle\psi_n(\lambda)|\psi_n(\lambda)\rangle = 1 + \lambda(a_n^{(1)} + a_n^{(1)*}) + \lambda^2(a_n^{(2)} + a_n^{(2)*} + \langle\psi_n^1|\psi_n^1\rangle) + \cdots. \tag{H.14}$$

Substituting the Ansatz (H.11) and the expansion (H.12) into Eq. (H.9) we obtain for the special case $\nu = n$

$$E_n(\lambda) = E_n^0 + \frac{\lambda\langle\phi_n|\mathcal{H}_1|\phi_n\rangle + \lambda^2\langle\phi_n|\mathcal{H}_1|\psi_n^1\rangle + \cdots}{1 + \lambda a_n^{(1)} + \lambda^2 a_n^{(2)} + \cdots}. \tag{H.15}$$

Expanding this expression in powers of λ we obtain

$$\begin{aligned} E_n(\lambda) = E_n^0 &+ \lambda\langle\phi_n|\mathcal{H}_1|\phi_n\rangle \\ &+ \lambda^2[\langle\phi_n|\mathcal{H}_1|\psi_n^1\rangle - \langle\phi_n|\mathcal{H}_1|\phi_n\rangle a_n^{(1)}] \\ &+ \lambda^3[\langle\phi_n|\mathcal{H}_1|\psi_n^2\rangle - \langle\phi_n|\mathcal{H}_1|\psi_n^1\rangle a_n^{(1)} - \langle\phi_n|\mathcal{H}_1|\phi_n\rangle a_n^{(2)}] + \cdots. \end{aligned} \tag{H.16}$$

This expansion defines the energy shift order by order,

$$E_n(\lambda) \equiv E_n^0 + \lambda\Delta E_n^{(1)} + \lambda^2\Delta E_n^{(2)} + \lambda^3\Delta E_n^{(3)} + \cdots, \tag{H.17}$$

where $\Delta E_n^{(p)}$ represents the pth-order contribution to the energy shift. With regard to the eigenstate $|\psi_n(\lambda)\rangle$, the perturbation can be regarded as giving rise to an admixture of all *other* states ($m \neq n$) as follows with the aid of the closure relation under the assumption $\langle\phi_n|\psi_n^1\rangle = 0$,

$$|\psi_n(\lambda)\rangle \equiv |\phi_n\rangle + \lambda\sum_m{}'|\phi_m\rangle\langle\phi_m|\psi_n^1\rangle + \lambda^2\sum_m{}'|\phi_m\rangle\langle\phi_m|\psi_n^2\rangle + \cdots. \tag{H.18}$$

Here the prime on the summation indicates $m \neq n$ (*i.e.*, the term $m = n$ is skipped in the summation). In terms of the coefficients $a_m^{(p)}$ the corrections to the wavefunction can be expressed as as

$$|\psi_n(\lambda)\rangle \equiv |\phi_n\rangle + \lambda\sum_m{}'a_m^{(1)}|\phi_m\rangle + \lambda^2\sum_m{}'a_m^{(2)}|\psi_m\rangle + \cdots. \tag{H.19}$$

Note that to calculate the energy shift to order $p \geq 1$ we need to know the wavefunction $|\psi_n^q\rangle$ to order $q \leq p - 1$. It is good to emphasize that there is no guarantee that the expansion (H.16) actually converges for $\lambda \to 1$. We will simply presume convergence, as is the case in many applications of practical interest. Convergence criteria and alternative perturbation methods can be found in advanced texts.

Before proceeding to the calculation of the energy shifts $\Delta E_n^{(p)}$ we return to Eq. (H.9) and derive a set of equations for the coefficients $a_\nu^{(p)}$, this time for the case $\nu = m \neq n$. Substituting Eqs. (H.11) and (H.12) for the case $\nu = m \neq n$ into Eq. (H.9) we obtain

$$E_n(\lambda) = E_m^0 + \frac{\lambda\langle\phi_m|\mathcal{H}_1|\phi_n\rangle + \lambda^2\langle\phi_m|\mathcal{H}_1|\psi_n^1\rangle + \cdots}{\lambda a_m^{(1)} + \lambda^2 a_m^{(2)} + \cdots}. \tag{H.20}$$

Replacing the l.h.s. by the expansion (H.17) and collecting the terms of equal power in λ we have

$$(E_n^0 - E_m^0)a_m^{(1)} = \langle\phi_m|\mathcal{H}_1|\phi_n\rangle \qquad \text{first order} \tag{H.21a}$$

$$\Delta E_n^{(1)}a_m^{(1)} + (E_n^0 - E_m^0)a_m^{(2)} = \langle\phi_m|\mathcal{H}_1|\psi_n^1\rangle \qquad \text{second order} \tag{H.21b}$$

$$\Delta E_n^{(2)}a_m^{(1)} + \Delta E_n^{(1)}a_m^{(2)} + (E_n^0 - E_m^0)a_m^{(3)} = \langle\phi_m|\mathcal{H}_1|\psi_n^2\rangle \qquad \text{third order} \tag{H.21c}$$

$$\cdots = \cdots .$$

These equations are valid for $m \neq n$. Extension to any order in λ is straightforward. Note that the parameter λ has dropped out of the expressions; it only served to identify the orders of the perturbation expansion. Note further that to calculate $a_m^{(p)}$ to order $p \geq 1$ we need to know the correction to the wavefunction $|\psi_n^q\rangle$ as well as the energy shift $\Delta E_n^{(q)}$ to order $q \leq p-1$.

Zeroth order

We are now prepared to calculate the energy shifts $\Delta E_n^{(p)}$. To zeroth order we have $E_n \simeq E_n^0$ and $a_m^{(0)} \simeq \langle\phi_m|\psi_n^0\rangle = \langle\phi_m|\phi_n\rangle = \delta_{mn}$. Note that the approximate wavefunction $|\psi_n\rangle \simeq |\phi_n\rangle$ is normalized.

H.2.0.1 First order

Proceeding to first order we compare Eqs. (H.17) and (H.16) to obtain

$$\Delta E_n^{(1)} = \langle\phi_n|\mathcal{H}_1|\phi_n\rangle. \tag{H.22}$$

With this result we expressed the first-order energy shifts in terms of the (known) unperturbed states $\{|\phi_n\rangle\}$. Eq. (H.22) is of enormous practical importance. It shows that in the presence of the perturbation $\mathcal{H}_1$ the first-order contribution to the energy is obtained by calculating the expectation value of $\mathcal{H}_1$ under the assumption that the wavefunctions remain unchanged. Also from the intuitive point of view this is plausible: we expect

$$\Delta E_n = \frac{\langle\phi_n|\mathcal{H}_1|\psi_n\rangle}{\langle\phi_n|\psi_n\rangle} \simeq \frac{\langle\phi_n|\mathcal{H}_1|\phi_n\rangle}{\langle\phi_n|\phi_n\rangle} = \langle\phi_n|\mathcal{H}_1|\phi_n\rangle \tag{H.23}$$

because replacing in Eq. (H.6) the exact (but unknown) state $|\psi_n\rangle$ by the only slightly different (but known) state $|\phi_n\rangle$ will hardly affect the result.

H.2.0.2 Second order

Comparing Eq. (H.16) with (H.17), and using the closure relation the second-order contribution to the energy shift takes the form

$$\Delta E_n^{(2)} = \sum_m \langle\phi_n|\mathcal{H}_1|\phi_m\rangle\langle\phi_m|\psi_n^1\rangle - \langle\phi_n|\mathcal{H}_1|\phi_n\rangle a_n^{(1)}. \tag{H.24}$$

Separating the term $m = n$ from the summation it cancels against the second term on the r.h.s. and Eq. (H.24) reduces to

$$\Delta E_n^{(2)} = {\sum_m}' a_m^{(1)}\langle\phi_n|\mathcal{H}_1|\phi_m\rangle, \tag{H.25}$$

where the prime indicates the constraint $m \neq n$. Interestingly, the result for $\Delta E_n^{(2)}$ is independent of $a_n^{(1)}$. This leaves us the freedom to choose the value of $a_n^{(1)}$ to best serve our purpose. The obvious choice is $a_n^{(1)} = 0$. This not only assures the normalization of the wavefunction to first order in λ, see Eq. (H.14), but also has the advantage that the expression for the third-order shift simplifies, see Eq. (H.16). Eq. (H.25) shows that the second-order correction to the energy follows from the first-order correction to the state - see Eq. (H.19),

$$|\psi_n(\lambda)\rangle \simeq |\phi_n\rangle + \lambda \sum_m{}' a_m^{(1)} |\phi_m\rangle. \tag{H.26}$$

To obtain the coefficient $a_m^{(1)}$ we rewrite Eq. (H.21a) in the form

$$a_m^{(1)} = \frac{\langle\phi_m|\mathcal{H}_1|\phi_n\rangle}{E_n^0 - E_m^0} \quad \text{with } m \neq n. \tag{H.27}$$

As this expression is not defined for $E_n^0 = E_m^0$ it is *only valid in the absence of degeneracy.* Substituting Eq. (H.27) into Eq. (H.26) the *first-order* expression for the *state* is given by

$$|\psi_n\rangle \simeq |\phi_n\rangle + \sum_m{}' |\phi_m\rangle \frac{\langle\phi_m|\mathcal{H}_1|\phi_n\rangle}{E_n^0 - E_m^0}. \tag{H.28}$$

Substituting Eq. (H.27) into Eq. (H.25) the *second-order* correction to the *energy* is found to be

$$\Delta E_n^{(2)} = \sum_m{}' \frac{|\langle\phi_n|\mathcal{H}_1|\phi_m\rangle|^2}{E_n^0 - E_m^0}. \tag{H.29}$$

Note that this second-order contribution to the energy shift consists of a summation over all states $|\phi_m\rangle$ except the state $|\phi_n\rangle$ under consideration. This feature of second-order perturbation theory is called summation over *virtual excitations* or *virtual transitions to excited states.*

Closure approximation: It is possible to set limits on $|\Delta E_n^{(2)}|$ by over-estimating or under-estimating all terms of the summation (H.29). We illustrate this for the ground state ($n = 0$). Since $\left|E_1^0 - E_0^0\right| \leq \left|E_m^0 - E_0^0\right| \leq \left|E_0^0\right|$ the following inequality holds:

$$\frac{1}{|E_0^0|} \sum_m{}' |\langle\phi_0|\mathcal{H}_1|\phi_m\rangle|^2 \leq |\Delta E_0^{(2)}| \leq \frac{1}{|E_1^0 - E_0^0|} \sum_m{}' |\langle\phi_0|\mathcal{H}_1|\phi_m\rangle|^2 \tag{H.30}$$

Using the closure relation the summation can be rewritten in the form

$$\sum_m{}' |\phi_m\rangle\langle\phi_m| = \mathbb{1} - |\phi_n\rangle\langle\phi_n| \tag{H.31}$$

and the inequality becomes

$$\frac{\langle\phi_0|\mathcal{H}_1^2|\phi_0\rangle - |\langle\phi_0|\mathcal{H}_1|\phi_0\rangle|^2}{|E_0^0|} \leq |\Delta E_0^{(2)}| \leq \frac{\langle\phi_0|\mathcal{H}_1^2|\phi_0\rangle - |\langle\phi_0|\mathcal{H}_1|\phi_0\rangle|^2}{|E_1^0 - E_0^0|}, \tag{H.32}$$

The quantity

$$(\Delta\mathcal{H}_1)^2 = \langle\phi_0|\mathcal{H}_1^2|\phi_0\rangle - |\langle\phi_0|\mathcal{H}_1|\phi_0\rangle|^2$$

is the variance of the perturbing term $\mathcal{H}_1$ in the state $|\phi_0\rangle$. This approximation is known as the *closure approximation.*

H.2.0.3 Third order

In many cases the determination of the first-order contribution $\Delta E_n^{(1)}$ is already adequate for a good estimate of the level shift, with $\Delta E_n^{(2)}$ serving as a tool to get an impression of the convergence of the perturbation expansion. When the first-order shift happens to be zero, $\Delta E_n^{(1)} = 0$, the second order contribution may still be nonzero and provide the leading contribution to the shift of the energy levels. Rarely we will need the third-order contribution. The reason to proceed anyhow and calculate the third order is that a new element enters the discussion with consequences for the normalization of the wavefunction to second order in λ. Comparing Eqs. (H.17) and (H.16) and using the choice $a_n^{(1)} = 0$ the third-order contribution to the energy shift can be written in the form

$$\Delta E_n^{(3)} = \sum_m \langle\phi_n|\mathcal{H}_1|\phi_m\rangle\langle\phi_m|\psi_n^2\rangle - \langle\phi_n|\mathcal{H}_1|\phi_n\rangle a_n^{(2)}. \tag{H.33}$$

As the term $m = n$ from the summation cancels against the second term on the r.h.s. the expression for $\Delta E_n^{(3)}$ becomes

$$\Delta E_n^{(3)} = {\sum_m}' a_m^{(2)}\langle\phi_n|\mathcal{H}_1|\phi_m\rangle. \tag{H.34}$$

The result for $\Delta E_n^{(3)}$ is independent of $a_n^{(2)}$. Thus, like for $a_n^{(1)}$ we have the freedom to choose $a_n^{(2)}$. Choosing $a_n^{(2)} = 0$ has the advantage that the expression for the fourth-order term simplifies. However, unlike in the second-order case this choice does not conserve the normalization as is evident from Eq. (H.14). Normalization requires $a_n^{(2)} + a_n^{(2)*} + \langle\psi_n^1|\psi_n^1\rangle = 0$. Hence, we have the choice between unit normalization or a simplified hierarchy of equations of higher order. To keep the procedure simple we choose for the latter ($a_n^{(2)} = 0$) and correct for the loss of normalization by renormalizing the final result. We return to this renormalization below. To determine the coefficient $a_m^{(2)}$ for $m \neq n$ we use the closure relation to rewrite Eq. (H.21b) in the form

$$(E_n^0 - E_m^0)a_m^{(2)} = {\sum_\nu}' \langle\phi_m|\mathcal{H}_1|\phi_\nu\rangle\langle\phi_\nu|\psi_n^{(1)}\rangle - \Delta E_n^{(1)} a_m^{(1)} \quad \text{with } m \neq n, \tag{H.35}$$

where the term $\nu = n$ could be excluded because $a_n^{(1)}$ was previously chosen to be zero. Substituting the first-order results (H.22) and (H.27) the expression for the second-order coefficient becomes

$$a_m^{(2)} = {\sum_\nu}' \frac{\langle\phi_m|\mathcal{H}_1|\phi_\nu\rangle\langle\phi_\nu|\mathcal{H}_1|\phi_n\rangle}{(E_n^0 - E_\nu^0)\,(E_n^0 - E_m^0)} - \frac{\langle\phi_m|\mathcal{H}_1|\phi_n\rangle\langle\phi_n|\mathcal{H}_1|\phi_n\rangle}{(E_n^0 - E_m^0)^2} \quad \text{with } m \neq n. \tag{H.36}$$

Substituting this result into Eq. (H.34) we find for the third-order shift

$$\Delta E_n^{(3)} = {\sum_{m,\nu}}' \frac{\langle\phi_n|\mathcal{H}_1|\phi_m\rangle\langle\phi_m|\mathcal{H}_1|\phi_\nu\rangle\langle\phi_\nu|\mathcal{H}_1|\phi_n\rangle}{(E_n^0 - E_\nu^0)\,(E_n^0 - E_m^0)} - \langle\phi_n|\mathcal{H}_1|\phi_n\rangle {\sum_m}' \frac{|\langle\phi_m|\mathcal{H}_1|\phi_n\rangle|^2}{(E_n^0 - E_m^0)^2}. \tag{H.37}$$

H.2.1 Renormalization of the wavefunction

It is straightforward to show by induction that Eq. (H.25) can be generalized to arbitrary order by choosing $a_n^{(p)} = 0$ for all orders $p \geq 1$. With this convention we have $a_n(\lambda) = 1$ and the expression for the energy shifts (H.15) reduces to

$$\Delta E_n(\lambda) = \lambda\langle\phi_n|\mathcal{H}_1|\phi_n\rangle + \lambda^2\langle\phi_n|\mathcal{H}_1|\psi_n^1\rangle + \cdots = \lambda\langle\phi_n|\mathcal{H}_1|\psi_n(\lambda)\rangle. \tag{H.38}$$

Here we recognize a conveniently simplified form of Eq. (H.6). However, as mentioned above, with this convention the normalization differs from unity,

$$\langle\psi_n(\lambda)|\psi_n(\lambda)\rangle = 1 + \lambda^2\langle\psi_n^1|\psi_n^1\rangle + \lambda^3[\langle\psi_n^1|\psi_n^2\rangle + \langle\psi_n^2|\psi_n^1\rangle] + \cdots . \tag{H.39}$$

As the result (H.38) depends on the norm of $|\psi_n(\lambda)\rangle$ we have to correct for the normalization error by multiplying with a renormalization factor,

$$\Delta E_n(\lambda) = \frac{\lambda\langle\phi_n|\mathcal{H}_1|\psi_n(\lambda)\rangle}{\langle\psi_n(\lambda)|\psi_n(\lambda)\rangle^{1/2}} = \lambda\langle\phi_n|\mathcal{H}_1|\psi_n(\lambda)\rangle Z^{1/2}. \tag{H.40}$$

The quantity

$$Z = \frac{1}{\langle\psi_n(\lambda)|\psi_n(\lambda)\rangle} = 1 - \lambda^2\langle\psi_n^{(1)}|\psi_n^{(1)}\rangle + \cdots \tag{H.41}$$

is called the *renormalization constant.* Note that the renormalization correction enters as a second-order correction in λ. Using the closure relation as well as Eq. (H.27) the renormalization constant becomes

$$Z = 1 - \lambda^2 \sum_m{}' \frac{|\langle\phi_n|\,\mathcal{H}_1\,|\phi_m\rangle|^2}{(E_n^0 - E_m^0)^2} + \cdots . \tag{H.42}$$

H.3 Perturbation theory for degenerate levels

In this section we turn to the perturbation theory for a g-fold *degenerate* energy level E_n^0 of the unperturbed Hamiltonian $\mathcal{H}_0$, corresponding to *bound states* $|\phi_{n,k}\rangle$, with $k \in \{1, \cdots, g\}$, where the value of g will generally depend on the primary quantum number n. In this case the Schrödinger equation of $\mathcal{H}_0$ takes the form

$$\mathcal{H}_0\,|\phi_{n,k}\rangle = E_n^0\,|\phi_{n,k}\rangle \text{ with } k \in \{1, \cdots, g\}, \tag{H.43}$$

where the manifold of normalized eigenstates $\{|\phi_{n,k}\rangle\}$, with $k \in \{1, \cdots, g\}$, span the degenerate subspace of level E_n^0 but are not *necessarily* orthogonal,

$$S_{ik} = \langle\phi_{n,i}|\phi_{n,k}\rangle \neq \delta_{ik}. \tag{H.44}$$

The quantity S_{ik} represents the overlap matrix for the eigenstates $|\phi_{n,k}\rangle$ of the degenerate subspace. The set $\{|\phi_{n,k}\rangle\}$, with $k \in \{1, \cdots, g\}$, can of course always be orthogonalized to provide a complete set of orthonormal eigenstates. Implicitly, *we suppose that this orthogonalization has been done*

$$\langle\phi_{n,i}|\phi_{n,k}\rangle = \delta_{ik}. \tag{H.45}$$

As we will see this diagonalization, although convenient, is not sufficient to deal with the degenerate case.

Ordinary perturbation theory fails in the degenerate case by divergence at the level of Eqs. (H.27) and (H.29) because $E_{n,k}^0 = E_{n,l}^0$ for $k \neq l \in \{1, \cdots, g\}$. As will appear, for a degenerate manifold of states, the effect of the perturbation is not so much an over-all shift of the manifold but a relative shift of the degenerate sublevels with respect to each other. This is called *lifting of the degeneracy* by level splitting. To approximate the perturbed basis states $\{|\psi_{n,k}\rangle\}$ we reconsider the Hamiltonian (H.7) with corresponding Schrödinger equation

$$\mathcal{H}(\lambda)\,|\psi_{n,k}(\lambda)\rangle = E_{n,k}(\lambda)\,|\psi_{n,k}(\lambda)\rangle\,. \tag{H.46}$$

For this case the expression (H.9) takes the form

$$E_{n,k}(\lambda) = E_\nu^0 + \lambda\frac{\langle\phi_{\nu,i}|\mathcal{H}_1\,|\psi_{n,k}(\lambda)\rangle}{\langle\phi_{\nu,i}|\psi_{n,k}(\lambda)\rangle}. \tag{H.47}$$

To obtain approximate expressions for the levels $E_{n,k}(\lambda)$ we start, in analogy with Eq. (H.11), with the Ansatz

$$|\psi_{n,k}(\lambda)\rangle \equiv |\phi_{n,k}\rangle + \lambda|\psi_{n,k}^1\rangle + \lambda^2|\psi_{n,k}^2\rangle + \cdots . \tag{H.48}$$

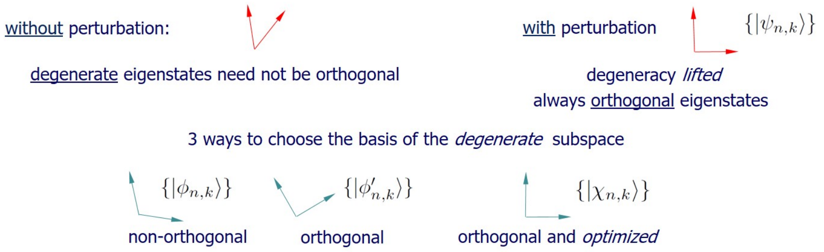

Figure H.1: Heuristic diagram for the selection of the optimal basis for perturbation theory of a degenerate level. The perturbation removes the ambiguity in the choice of basis vectors and this imposes a constraint in the choice of the unperturbed basis.

However, in the present case immediately an ambiguity arises. It is not obvious *which* of the unperturbed states from the degenerate manifold $\{|\phi_{n,k}\rangle\}$ of energy E_n^0 should be chosen in the expansion. Actually, *any* normalized linear combination of states from the degenerate the manifold $\{|\phi_{n,k}\rangle\}$ will also be an eigenstate of $\mathcal{H}_0$ of energy E_n^0. Therefore, it is not *a priori* clear how to choose an orthonormal set $\{|\chi_{n,k}\rangle\}$ within the degenerate subspace of the manifold n such that the $|\psi_{n,k}^p\rangle$ with $p \geq 1$ represent a small correction with respect to $|\chi_{n,k}\rangle$ for $\lambda \to 1$. This becomes clear only *after* we know how the symmetry of $\mathcal{H}_0$ is broken by the perturbation $\mathcal{H}_1$.

Let us presume that $\{|\chi_{n,i}\rangle\}$ is the (unknown) orthonormal set of the manifold n that we are looking for and $\{|\phi_{m,k}\rangle\}$ is the subset of the basis $\{|\phi_{n,k}\rangle\}$ for which $m \neq n$, (see Fig. H.1). The selection of the optimal basis is illustrated in Fig. H.1. For the optimal basis the following closure relation holds

$$\mathbb{1} = \sum_i |\chi_{n,i}\rangle\langle\chi_{n,i}| + \sum_{m,k}{}' |\phi_{m,k}\rangle\langle\phi_{m,k}| \equiv \sum_{\nu,\mu} |\psi_{\nu,\mu}^0\rangle\langle\psi_{\nu,\mu}^0|, \tag{H.49}$$

where the prime indicates $m \neq n$ and

$$\{|\psi_{\nu,\mu}^0\rangle\} = \begin{cases} \{|\chi_{n,\mu}\rangle\} \text{ for } \nu = n \\ \{|\phi_{\nu,\mu}\rangle\} \text{ for } \nu \neq n. \end{cases} \tag{H.50}$$

For this new set of eigenstates the Ansatz (H.48) takes the form

$$|\psi_{n,k}(\lambda)\rangle \equiv |\chi_{n,k}\rangle + \lambda|\psi_{n,k}^1\rangle + \lambda^2|\psi_{n,k}^2\rangle + \cdots . \tag{H.51}$$

This implies for the function $a_{\nu\mu,nk}(\lambda)$ the following expansion in powers of λ:

$$a_{\nu\mu,nk}(\lambda) = \langle\psi_{\nu,\mu}^0|\psi_{n,k}(\lambda)\rangle = \delta_{\nu\mu,nk} + \lambda a_{\nu\mu,nk}^{(1)} + \lambda^2 a_{\nu\mu,nk}^{(2)} + \cdots , \tag{H.52}$$

where the coefficients are defined by $a_{\nu\mu,nk}^{(p)} = \langle\psi_{\nu,\mu}^0|\psi_{n,k}^p\rangle$. Substituting this expansion into Eq. (H.47) we obtain for the special case $\nu = n, \mu = k$

$$E_{n,k}(\lambda) = E_n^0 + \frac{\lambda\langle\chi_{n,k}|\mathcal{H}_1|\chi_{n,k}\rangle + \lambda^2\langle\chi_{n,k}|\mathcal{H}_1|\psi_{n,k}^1\rangle + \cdots}{1 + \lambda a_{nk,nk}^{(1)} + \lambda^2 a_{nk,nk}^{(2)} + \cdots}. \tag{H.53}$$

Expanding Eq. (H.53) in powers of λ we obtain

$$E_{n,k}(\lambda) = E_n^0 + \lambda\langle\chi_{n,k}|\mathcal{H}_1|\chi_{n,k}\rangle + \lambda^2[\langle\chi_{n,k}|\mathcal{H}_1|\psi_{n,k}^1\rangle - \langle\chi_{n,k}|\mathcal{H}_1|\chi_{n,k}\rangle a_{nk,nk}^{(1)}] + \cdots . \tag{H.54}$$

This expression defines the energy shifts order by order,

$$E_{n,k}(\lambda) \equiv E_n^0 + \lambda\Delta E_{n,k}^{(1)} + \lambda^2\Delta E_{n,k}^{(2)} + \lambda^3\Delta E_{n,k}^{(3)} + \cdots . \tag{H.55}$$

H.3.0.1 First order

Comparing Eqs. (H.54) and (H.55) we obtain for the first-order shift,

$$\Delta E^{(1)}_{n,k} = \langle \chi_{n,k}|\mathcal{H}_1|\chi_{n,k}\rangle. \tag{H.56}$$

Note that this expression coincides with the expression for the first-order energy shift given by Eq. (H.22) from non-degenerate perturbation theory. The coupling to other manifolds does not enter the expression; only matrix elements diagonal in the quantum number n appear. In this sense, the quantum number n is *always* conserved to *first* order in perturbation theory and n is called a "good quantum number to *first* order in perturbation theory".

H.3.0.2 Second order

Proceeding to second order we obtain with the aid of Eq. (H.49)

$$\Delta E^{(2)}_{n,k} = \sum_{m,l} \langle \chi_{n,k}|\mathcal{H}_1|\psi^0_{m,l}\rangle\langle \psi^0_{m,l}|\psi^1_{n,k}\rangle - \langle \chi_{n,k}|\mathcal{H}_1|\chi_{n,k}\rangle a^{(1)}_{nk,nk}. \tag{H.57}$$

This is the analogue of (H.24). Separating the term with $(m = n,\, l = k)$ from the summation it cancels against the subtracted term and we obtain

$$\Delta E^{(2)}_{n,k} = \sum_{m,l}{}' \langle \chi_{n,k}|\mathcal{H}_1|\phi_{m,l}\rangle a^{(1)}_{ml,nk}, \tag{H.58}$$

where the prime indicates the summation constraint $(m \neq n,\, l \neq k)$, which implies $|\psi^0_{m,l}\rangle = |\phi_{m,l}\rangle$ as follows from (H.50). As Eq. (H.58) does not depend on $a^{(1)}_{nk,nk}$ we may choose $a^{(1)}_{nk,nk} = 0$.

To determine the other coefficients $a^{(1)}_{ml,nk}$ we consider Eq. (H.47) for $(\nu, \mu) = (m, l) \neq (n, k)$

$$E_{n,k}(\lambda) = E^0_m + \frac{\lambda\langle \psi^0_{m,l}|\mathcal{H}_1|\chi_{n,k}\rangle + \lambda^2\langle \psi^0_{m,l}|\mathcal{H}_1|\psi^1_{n,k}\rangle + \cdots}{\lambda a^{(1)}_{ml,nk} + \lambda^2 a^{(2)}_{ml,nk} + \cdots}. \tag{H.59}$$

Replacing the l.h.s. by the expansion (H.55) and collecting the terms of first order in λ we obtain

$$(E^0_n - E^0_m)a^{(1)}_{ml,nk} = \langle \psi^0_{m,l}|\mathcal{H}_1|\chi_{n,k}\rangle. \tag{H.60}$$

Here we distinguish two cases:

- for $(m = n,\, l \neq k)$ we have
$$\langle \chi_{n,l}|\mathcal{H}_1|\chi_{n,k}\rangle = 0, \tag{H.61}$$
independent of the value of $a^{(1)}_{nl,nk}$; this provides us with the freedom to choose $a^{(1)}_{nl,nk} = 0$ for given n, k and all values of l.
- for $m \neq n$ we obtain, irrespective of the values of l and k,
$$a^{(1)}_{ml,nk} = \frac{\langle \phi_{m,l}|\mathcal{H}_1|\chi_{n,k}\rangle}{E^0_n - E^0_m}. \tag{H.62}$$

Substituting these expressions for $a^{(1)}_{ml,nk}$ the expression for the second order shift reduces to

$$\Delta E^{(2)}_{n,k} = \sum_{m,l}{}' \frac{|\langle \phi_{m,l}|\mathcal{H}_1|\chi_{n,k}\rangle|^2}{E^0_n - E^0_m}, \tag{H.63}$$

where the prime indicates the summation constraint $m \neq n$. Note that Eq. (H.63) is formally identical to the result (H.29) obtained with ordinary perturbation theory because summing over both m and l represents the summation over all states non-degenerate with the manifold $\{\chi_{n,k}\}$.

H.3.0.3 Relation with the unperturbed eigenstates

What remains to be done is to express the orthonormal set $\{|\chi_{n,k}\rangle\}$ in terms of the (known) set $\{|\phi_{n,k}\rangle\}$. From Eqs. (H.56) and (H.61) we find that this set diagonalizes the degenerate subspace,

$$\langle\chi_{n,l}|\mathcal{H}_1|\chi_{n,k}\rangle = \Delta E_{n,k}^{(1)}\delta_{kl}, \tag{H.64}$$

but in general not the rest of the Hilbert space - see (H.62),

$$\langle\phi_{m,l}|\mathcal{H}_1|\chi_{n,k}\rangle = (E_n^0 - E_m^0)a_{ml,nk}^{(1)} \neq 0 \quad \text{for } m \neq n. \tag{H.65}$$

Hence, the orthonormal set $\{|\chi_{n,k}\rangle\}$ represents a basis for the degenerate subspace. Only when the operators $\mathcal{H}_0$ and $\mathcal{H}_1$ commute they can share a complete basis for the full Hilbert space (see Problem F.1). Thus, *restricting ourselves to the degenerate subspace* we may write

$$\mathcal{H}_1|\chi_{n,k}\rangle = \varepsilon_k|\chi_{n,k}\rangle \quad \text{for } k \in \{1, \cdots, g\}, \tag{H.66}$$

where we use the shorthand notation $\varepsilon_k \equiv \Delta E_{n,k}^{(1)}$. The eigenstates of the (unknown) set $\{|\chi_{n,k}\rangle\}$ and the (known) set $\{|\phi_{n,k}\rangle\}$ are related by a basis transformation,

$$|\chi_{n,k}\rangle = \sum_j c_{jk}|\phi_{n,j}\rangle \quad \text{with } \sum_j |c_{jk}|^2 = 1, \tag{H.67}$$

where the coefficients $c_{jk} \equiv \langle\phi_{n,j}|\chi_{n,k}\rangle$ are yet to be determined. These coefficients follow in three steps. First we project both sides of the Schrödinger equation for the degenerate subspace as given by Eq. (H.66) onto an arbitrary state $|\phi_{n,i}\rangle$ from the (known) set $\{|\phi_{n,k}\rangle\}$,

$$\langle\phi_{n,i}|\mathcal{H}_1|\chi_{n,k}\rangle = \varepsilon_k\langle\phi_{n,i}|\chi_{n,k}\rangle. \tag{H.68}$$

In the second step we replace $|\chi_{n,k}\rangle$ in Eq. (H.68) by the superposition (H.67) and obtain a set of g equations with g unknowns, one for each possible choice of $i \in \{1, \cdots, g\}$,

$$\sum_j c_{jk}[\langle\phi_{n,i}|\mathcal{H}_1|\phi_{n,j}\rangle - \varepsilon_k\delta_{ij}] = 0. \tag{H.69}$$

The third step is to solve these equations, which is possible if and only if the secular equation is satisfied,

$$\det\left|H'_{ij} - \varepsilon\,\delta_{ij}\right| = 0, \tag{H.70}$$

where

$$H'_{ij} = \langle\phi_{n,i}|\mathcal{H}_1|\phi_{n,j}\rangle \tag{H.71}$$

is the coupling matrix. Eq. (H.70) represents a polynomial of order g in powers of ε and is called the characteristic polynomial (secular equation) of the set of equations. The set of equations has g solutions for the set of coefficients $\{c_{1k}, \cdots c_{gk}\}$, each corresponding to one of the roots $\varepsilon_k \in \{\varepsilon_1, \cdots, \varepsilon_g\}$ of the characteristic polynomial. Finding these solutions amounts to the diagonalization of a $g \times g$ matrix eigenvalue problem, well-known from linear algebra. The roots correspond to the eigenvalues ε_k and the corresponding eigenvectors define the coefficients $\{c_{1k}, \cdots c_{gk}\}$. This completes our task of expressing $|\chi_{n,k}\rangle$ in terms of the (known) eigenstates $\{|\phi_{n,i}\rangle\}$ of the degenerate subspace of level n.

H.3.1 Reduction to ordinary first-order perturbation theory

Interestingly, in many practical cases involving degenerate levels we can calculate the perturbation shifts using the simple first-order expression form ordinary perturbation theory. In such cases it is said that "perturbation theory for degenerate levels *reduces to ordinary perturbation theory*". To introduce this topic we consider the special case in which we can select a basis $\{|\phi_{n,k}\rangle\}$ in which not only $\mathcal{H}_0$ but also $\mathcal{H}_1$ is diagonal,

$$\mathcal{H}_0|\phi_{n,k}\rangle = E_n^0|\phi_{n,k}\rangle \tag{H.72a}$$

$$\mathcal{H}_1|\phi_{n,k}\rangle = \Delta E_{n,k}|\phi_{n,k}\rangle. \tag{H.72b}$$

The existence of a basis $\{|\phi_{n,k}\rangle\}$ with the given properties is assured if the operators $\mathcal{H}_0$ and $\mathcal{H}_1$ commute (see Problem F.1). Obviously, in this case there is no need for explicit diagonalization because the full Hamiltonian is already diagonal, with the quantum number n associated with $\mathcal{H}_0$ and k with $\mathcal{H}_1$. This situation arises when, in the modeling of a physical system, a new feature is introduced; e.g., an external field. When the new feature involves a new degree of freedom (e.g., spin) the Hilbert space has to be expanded accordingly, turning the eigenstates $|\phi_n\rangle$ of $\mathcal{H}_0$ into degenerate manifolds $\{|\phi_{n,k}\rangle\}$ of $\mathcal{H}_0$. The energy shifts associated with the new feature are captured by the term $\mathcal{H}_1$ in the Hamiltonian. As the new Hamiltonian $\mathcal{H} = \mathcal{H}_0 + \mathcal{H}_1$ is already diagonal in the basis $\{|\phi_{n,k}\rangle\}$ we can restrict ourselves to calculating the energy shifts caused by the term $\mathcal{H}_1$,

$$\Delta E_{n,k} = \Delta E_{n,k}^{(1)} + \Delta E_{n,k}^{(2)} + \cdots \quad \text{for } k \in \{1, \cdots, g\}, \tag{H.73}$$

where

$$\Delta E_{n,k}^{(1)} = \langle\phi_{n,k}|\mathcal{H}_1|\phi_{n,k}\rangle \tag{H.74}$$

and

$$\Delta E_{n,k}^{(2)} = {\sum_{m,l}}' \frac{|\langle\phi_{m,l}|\mathcal{H}_1|\phi_{n,k}\rangle|^2}{E_n^0 - E_m^0} = 0. \tag{H.75}$$

Thus, the shift is given by the expression for "ordinary" *first* order perturbation theory because all terms of higher order ($\Delta E_{n,k}^{(2)}$, $\Delta E_{n,k}^{(3)}, \cdots$) vanish by orthogonality of the basis states $\{|\phi_{n,k}\rangle\}$, as follows directly by substituting (H.72b) into (H.75). This is of course as it should be because if the full Hamiltonian is already diagonal, we have the exact solution at our disposal and there is nothing that perturbation theory can add to this.

In view of the above, it is good practice to first check the commutation properties of $\mathcal{H}_0$ and $\mathcal{H}_1$ and search (in case $[\mathcal{H}_0, \mathcal{H}_1] = 0$) for a basis that is diagonal for all quantum numbers. Only if this search is unsuccessful we have to turn to perturbation theory for degenerate levels and diagonalize the perturbation matrix explicitly. Interestingly, in important cases (e.g., spin-orbit coupling) the commutation of the operators $\mathcal{H}_0$ and $\mathcal{H}_1$, although not exact, is close to perfect. In these cases we can take advantage of the rule that n is *always* a "good quantum number to *first* order in perturbation theory" and use the basis (H.50) for which $\mathcal{H}_1$ is only diagonal in the manifold of interest; i.e., $\mathcal{H}_1|\chi_{n,k}\rangle = \Delta E_{n,k}|\chi_{n,k}\rangle$. Whether first-order perturbation theory yields a sufficiently good approximation can only be justified by verifying that the higher-order shifts are sufficiently small. Fortunately, in many cases a rough estimate suffices to convince ourselves that this requirement is satisfied.

Comment A: the level splitting by the orbital Zeeman interaction $\mathcal{H}_Z$ is an example that can be analyzed with first-order perturbation theory in the basis of the Schrödinger Hamiltonian $\mathcal{H}_0$. This is possible because $[\mathcal{H}_0, \mathcal{H}_Z] = 0$. In this case the exact result coincides with the first-order expression from ordinary perturbation theory.

Comment B: the level shifts by the relativistic mass correction, the spin-orbit interaction and the hyperfine interaction are examples of cases where *full* commutation with the perturbation is absent but the Hamiltonian is close to diagonal in the basis of the subspace of interest because the principal quantum number is *always* a "good quantum number to *first* order in perturbation theory". Hence, this is a good approximation as long as the second- and higher-order contributions are negligible.

H.4 Example: the two-fold degenerate case

In this section we turn to the special case of a 2-fold *degenerate* manifold of two *bound states* $|a\rangle$ and $|b\rangle$ with primary quantum number n, unperturbed energy E_n^0 and satisfying the Schrödinger equation

$$\mathcal{H}_0 \, |\phi_{n,i}\rangle = E_n^0 \, |\phi_{n,i}\rangle \;\text{ with }\; |\phi_{n,i}\rangle \in \{|a\rangle \,, |b\rangle\}. \tag{H.76}$$

For simplicity the unperturbed states states $|a\rangle$ and $|b\rangle$ are presumed to be orthonormal. The full Hamiltonian $\mathcal{H} = \mathcal{H}_0 + \mathcal{H}_1$ satisfies the Schrödinger equation

$$\mathcal{H} \, |\psi_{n,k}\rangle = E_{n,k} \, |\psi_{n,k}\rangle \,, \tag{H.77}$$

where $E_{n,k} = E_n^0 + \Delta E_k$, with ΔE_k the energy shift of level $k \in \{1, 2\}$. In the perturbation theory for degenerate levels the first-order approximation to the level shift, $\Delta E_k \simeq \varepsilon_k$, is obtained by diagonalization of the degenerate subspace with respect to the perturbation $\mathcal{H}_1$. In this approximation the problem reduces to case (a) discussed for two-level systems in Appendix G.3.1.

Comment A: The two-level case is used to calculate the zero-field fine-structure splitting in hydrogen-like atoms and the zero-field hyperfine splitting of hydrogen-like atoms in the electronic ground state.

Comment B: The exchange splitting in the helium atom can be estimate by first-order perturbation theory of a two-fold degenerate level and corresponds to the symmetric case of strong coupling.

I

Variational Methods

I.1 Introduction

I.1.1 Fundamental theorem

The fundamental theorem of variational calculus states that the equation $M(x) = 0$ holds if the integral $I = \int_a^b M(x)h(x)dx$ vanishes for *any* smooth function $h(x)$. By smooth we mean in this context that $h(x)$, $h'(x)$ and $h''(x)$ are continuous.

I.1.2 Extremal values of a continuous function

In physics we often have to search for a *maximum* or *minimum* (i.e., *extremum*) of some function. So, let $f(\mathbf{v})$ be a *continuous* function of n variables, represented by the *real* vector $\mathbf{v} = (v_1, \cdots, v_n)$, defined on the *domain* $\mathbf{v} \in V$. In general $f(\mathbf{v})$ will not be bounded; i.e., have no extreme points. Therefore, we shall suppose that $f(\mathbf{v})$ has an extreme value at the point $\mathbf{v}_0$. Three types of extrema can be distinguished: (a) *critical* points (if $\partial_{\mathbf{v}} f(\mathbf{v})|_{\mathbf{v}=\mathbf{v}_0} = 0$); (b) *singular* points (if $\partial_{\mathbf{v}} f(\mathbf{v})$ does *not* exist at $\mathbf{v}_0$); (c) *boundary* points (if $\mathbf{v}_0$ is a point at the boundary of the domain V). Here $\partial_{\mathbf{v}}$ represents the gradient with respect to the variables $v_1, \cdots, v_n$. Inversely, if we have identified a critical, singular or boundary point, this is not automatically an extreme point. The point can also be a *local* rather than a *global* extremum or some kind of *saddle* point. In such cases further inspection will be necessary and may be labor intensive.

I.1.3 Extremal values of a function in the presence of constraints - Lagrange multipliers

In important cases we have to search for the extrema of the function $f(\mathbf{v})$ in the presence of one or more *constraints*. Such a constraint can be an inequality (e.g., restricting the domain of definition of the function) or an equality (e.g., a normalization condition). In the latter case the number of independent variables is reduced, which means that in principle one of the variables could be eliminated but for many types of constraints this turns out to be impractical.

For *smooth* functions we can turn to the method of *Lagrange multipliers*. To introduce this method we consider again the function $f(\mathbf{v})$ of n variables, represented by the *real* vector $\mathbf{v} = (v_1, \cdots, v_n)$, defined on the *domain* $\mathbf{v} \in V$ and subject to $m \leq n-1$ equality constraints

$$g_j(\mathbf{v}) = 0, \quad (1 \leq j \leq m). \tag{I.1}$$

If $f(\mathbf{v})$ has a *critical* point at $\mathbf{v}_0$ we can define a function of $n+m$ variables,

$$\mathcal{L}(\mathbf{v}, \lambda_1, \cdots \lambda_m) = f(\mathbf{v}) + \lambda_1 g_1(\mathbf{v}) + \cdots + \lambda_m g_m(\mathbf{v}), \tag{I.2}$$

with the property that $\mathcal{L}(\mathbf{v}, \lambda_1, \cdots \lambda_m)$ has a *critical* point at $(\mathbf{v}_0, \lambda_1, \cdots \lambda_m)$ provided $\partial_{\mathbf{v}} g_j(\mathbf{v}_0) \neq 0$ for $1 \leq j \leq m$. The function $\mathcal{L}(\mathbf{v}, \lambda_1, \cdots \lambda_m)$ is called the Lagrangian of the function $f(\mathbf{v})$ under the constraints $g_j(\mathbf{v}) = 0$ and $\lambda_1, \cdots \lambda_m$ are called *Lagrange multipliers.* Any critical point must satisfy the set of $n + m$ equations

$$\frac{\partial \mathcal{L}}{\partial v_i} = 0 \quad (1 \leq i \leq n) \tag{I.3}$$

$$\frac{\partial \mathcal{L}}{\partial \lambda_j} = 0 \quad (1 \leq j \leq m)\,. \tag{I.4}$$

I.2 Rayleigh-Ritz variational principle

In this section we introduce the variational principle for the determination of eigenvalues and eigenfunctions of a quantum mechanical system. According to this principle any state $|\psi\rangle$ in the Hilbert space of the Hamiltonian $\mathcal{H}$ for which the expectation value

$$E[\psi] = \frac{\langle\psi|\mathcal{H}|\psi\rangle}{\langle\psi|\psi\rangle} \tag{I.5}$$

is stationary under *arbitrary functional variations* of the state $|\psi\rangle$, is an eigenstate of $\mathcal{H}$ with eigenvalue $E[\psi]$.

To derive this theorem we consider the change of the energy functional $E[\psi] = \langle\psi|\mathcal{H}|\psi\rangle$ under an arbitrary variation $\psi \to \psi + \delta\psi$

$$\delta E = E[\psi + \delta\psi] - E[\psi] = \frac{\langle\psi + \delta\psi|\mathcal{H}|\psi + \delta\psi\rangle - E\langle\psi + \delta\psi|\psi + \delta\psi\rangle}{\langle\psi + \delta\psi|\psi + \delta\psi\rangle}. \tag{I.6}$$

Expanding this expression up to lowest order in the variation we obtain with the aid of Eq. (I.5)

$$\begin{aligned}\langle\psi|\psi\rangle\delta E + \cdots &= \langle\psi|\mathcal{H}|\psi\rangle + \langle\delta\psi|\mathcal{H}|\psi\rangle + \langle\psi|\mathcal{H}|\delta\psi\rangle - E\langle\psi|\psi\rangle - E\langle\delta\psi|\psi\rangle - E\langle\psi|\delta\psi\rangle + \cdots \\ &= \langle\delta\psi|\mathcal{H} - E|\psi\rangle + \langle\psi|\mathcal{H} - E|\delta\psi\rangle + \cdots\,.\end{aligned} \tag{I.7}$$

Hence, for $E[\psi]$ to be stationary ($\delta E = 0$) under real variations of the state vector we require

$$\langle\psi|\psi\rangle\delta E = \langle\delta\psi|\mathcal{H} - E|\psi\rangle + \langle\psi|\mathcal{H} - E|\delta\psi\rangle = 0. \tag{I.8}$$

As $\mathcal{H}$ is an hermitian operator this condition can be written in the form

$$\langle\delta\psi|\mathcal{H} - E|\psi\rangle + \langle\delta\psi|\mathcal{H} - E|\psi\rangle^* = 0. \tag{I.9}$$

This shows that the variation of the bra $\langle\psi|$ gives rise to a term which is the complex conjugate of the term arising from the variation of the ket $|\psi\rangle$, which has the convenient consequence that if the energy is stationary under variation of $\langle\psi|$, the condition for being stationary under variation of $|\psi\rangle$ is simultaneously satisfied. Hence, we can restrict the variational procedure to the variation of *either* $\langle\psi|$ *or* $|\psi\rangle$. To complete the derivation we note that the condition

$$\langle\delta\psi|\mathcal{H} - E|\psi\rangle = 0 \text{ under arbitrary variation of } \psi \tag{I.10}$$

can only be satisfied if $|\psi\rangle$ is a stationary state of the system with eigenvalue E,

$$\mathcal{H}|\psi\rangle = E|\psi\rangle. \tag{I.11}$$

Eq. (I.5) is sometimes referred to as the *Rayleigh ratio* as it can be identified with the Lagrange multiplier for the normalization constraint $\langle\psi|\psi\rangle = \mathcal{N}$ in the lagrangian variation of the functional $f[\psi] = \langle\psi|\mathcal{H}|\psi\rangle$ - see Problem I.1. The variational principle was introduced by Rayleigh in 1873 [91] for the identification of the eigenmodes of acoustical systems. The method was further developed by Ritz in 1909 [92].

Problem I.1. Show that the Rayleigh ratio (I.5) can be identified with the Lagrange multiplier for the normalization constraint $\langle\psi|\psi\rangle = \mathcal{N}$ of the functional $f[\psi] = \langle\psi|\mathcal{H}|\psi\rangle$.

Solution. The Lagrangian for the variation of $f[\psi] = \langle\psi|\mathcal{H}|\psi\rangle$ under the constraint $\langle\psi|\psi\rangle = 1$ is given by

$$\mathcal{L} = \langle\psi|\mathcal{H}|\psi\rangle + \lambda(\langle\psi|\psi\rangle - \mathcal{N}).$$

This Lagrangian is stationary if

$$\delta\mathcal{L} = \langle\psi + \delta\psi|\mathcal{H}|\psi + \delta\psi\rangle + \lambda\langle\psi + \delta\psi|\psi + \delta\psi\rangle = 0,$$

which is satisfied for

$$-\lambda = \frac{\langle\psi + \delta\psi|\mathcal{H}|\psi + \delta\psi\rangle}{\langle\psi + \delta\psi|\psi + \delta\psi\rangle} \underset{\delta\psi\to 0}{=} \frac{\langle\psi|\mathcal{H}|\psi\rangle}{\langle\psi|\psi\rangle} = E[\psi]. \qquad \square$$

I.2.1 Estimating the ground state energy

The "arbitrary" variations considered in the variational principle remain meaningless unless the eigenmodes of the system are known. So what to do if the eigenstates of a quantum mechanical system are unknown? In the present section we show that the ground state energy of a quantum mechanical system can be found or at least approximated by cleverly choosing a *trial* wavefunction in which we try to include all our knowledge (or intuition) about the system, for instance by imposing a known symmetry. To demonstrate the procedure we consider a physical system described by the Hamiltonian $\mathcal{H}$, for which a complete set of (unknown) eigenstates $\{|\psi_n\rangle\}$ satisfy the Schrödinger equation

$$\mathcal{H}|\psi_n\rangle = E_n|\psi_n\rangle. \tag{I.12}$$

Here $E_0, E_1, E_2, \cdots$ are the eigenvalues in order of growing energy, E_0 being the energy of the (non-degenerate) ground state $|\psi_0\rangle$. Let us denote the trial state of the system by $|\chi\rangle$. The corresponding trial wavefunction $\chi(\mathbf{r})$ is given a functional form (preferably norm conserving) involving on one or more coefficients $\alpha, \beta, \gamma, \cdots$ which serve as *variational parameters.* In general $|\chi\rangle$ will not be an eigenstate of $\mathcal{H}$ and is not necessarily normalized. Expressing $|\chi\rangle$ as a linear combination of the basis states $\{|\psi_n\rangle\}$ we have

$$|\chi(\alpha, \beta, \gamma, \cdots)\rangle = \sum_n a_n(\alpha, \beta, \gamma, \cdots)|\psi_n\rangle. \tag{I.13}$$

Since $E_n > E_0$, with $n > 0$, we can derive the following inequality for the expectation value of $\mathcal{H}$,

$$\langle\chi|\mathcal{H}|\chi\rangle = \sum_{mn} a_m^* a_n \langle\psi_m|\mathcal{H}|\psi_n\rangle = \sum_n |a_n|^2 E_n \geq E_0 \sum_n |a_n|^2. \tag{I.14}$$

With the aid of this inequality we obtain for the energy of the system

$$E(\alpha, \beta, \gamma, \cdots) = \frac{\langle\chi|\mathcal{H}|\chi\rangle}{\langle\chi|\chi\rangle} \geq E_0. \tag{I.15}$$

This expression is intuitively clear: an arbitrary state will in general not be the ground state and therefore have an energy larger than E_0. The better we succeed in capturing the properties of the ground state in the trial state the lower will be the energy and the better will be our estimate of E_0. Hence, this important theorem can be used to derive an upper bound for the ground-state energy of the system. By variation of the parameters $\alpha, \beta, \gamma, \cdots$ we can minimize the energy of our trial state. The minimum is obtained if the following equations are satisfied

$$\frac{\partial E(\alpha, \beta, \gamma, \cdots)}{\partial\alpha} = \frac{\partial E(\alpha, \beta, \gamma, \cdots)}{\partial\beta} = \frac{\partial E(\alpha, \beta, \gamma, \cdots)}{\partial\gamma} = \cdots = 0. \tag{I.16}$$

In view of the inequality (I.15) the minimal value must be larger or equal than E_0. Accordingly, simultaneously imposing the conditions (I.16) is not equivalent to an *arbitrary* variation of $|\psi_0\rangle$. In other words, minimizing the energy by variation of the trial wavefunction does not lead us necessarily to the exact state. However, the procedure neither excludes this possibility. In Problem I.2 we demonstrate the method by obtaining an upper bound for the ground state energy of a harmonic oscillator.

Problem I.2. The Hamiltonian of the 1D harmonic oscillator is given by

$$\mathcal{H} = -\frac{\hbar^2}{2m}\frac{d^2}{dx^2} + \frac{1}{2}m\omega^2 x^2.$$

Determine an upper bound for the ground state energy of the 1D harmonic oscillator using the variational trial function $\chi(x) = \exp[-\frac{1}{2}\alpha x^2]$. Compare this value with the exact value.

Solution. Applying the inequality (I.15) the energy of the trial state $\chi(x)$ satisfies the relation

$$E(\alpha) = \frac{\int \exp[-\frac{1}{2}\alpha x^2]\mathcal{H}\exp[-\frac{1}{2}\alpha x^2]dx}{\int \exp[-\alpha x^2]dx} \geq E_0.$$

Substituting the expression for $\mathcal{H}$ and evaluating the integrals we obtain

$$E(\alpha) = -\frac{\hbar^2}{2m\alpha}\frac{\int_0^\infty \exp[-\frac{1}{2}x^2]\frac{d^2}{dx^2}\exp[-\frac{1}{2}x^2]dx}{\int_0^\infty \exp[-x^2]dx} + \tfrac{1}{2}m\omega^2\alpha\frac{\int_0^\infty x^2\exp[-x^2]dx}{\int_0^\infty \exp[-x^2]dx} = \frac{\hbar^2}{4m\alpha} + \tfrac{1}{4}m\omega^2\alpha \geq E_0.$$

In this case we have only one variational parameter. Varying $E(\alpha)$ with respect to α the stationary value is reached for

$$\frac{\partial E}{\partial \alpha} = -\frac{\hbar^2}{4m\alpha^2} + \tfrac{1}{4}m\omega^2 = 0,$$

which implies $\alpha = \hbar/m\omega$. It is easily verified that the stationary value corresponds to the *minimum* of the function $E(\alpha)$ and substituting the value $\alpha = \hbar/m\omega$ we obtain

$$E = \tfrac{1}{2}\hbar\omega.$$

This happens to the be the exact value because our trial function is of the same form as the true ground state. Any other choice of trial function will yield $E(\alpha) > \frac{1}{2}\hbar\omega$. □

I.3 Variational method for degenerate states

In many cases we have to deal with the phenomenon of *lifting of a degeneracy* by some form of symmetry breaking in the Hamiltonian $\mathcal{H}$. To discuss this phenomenon we consider a set with g degenerate states which we shall denote by $|\chi_i\rangle$, with $i \in \{1, \cdots, g\}$. The states $|\chi_i\rangle$ need not be orthogonal or normalized. Because the states are degenerate we have

$$E^0 = \frac{\langle\chi_i|\,\mathcal{H}_0\,|\chi_i\rangle}{\langle\chi_i|\chi_i\rangle} \text{ for } i \in \{1, \cdots, g\}, \tag{I.17}$$

where $\mathcal{H}_0$ is the Hamiltonian without symmetry breaking. To analyze how the degeneracy of the states $|\chi_i\rangle$ is lifted we choose a trial wavefunction in which g variational parameters $c_1, c_2, \cdots, c_g$ are chosen as the coefficients of a linear combination of the type

$$|\psi_k\rangle = \sum_{i=1}^{g} c_i\,|\chi_i\rangle\,. \tag{I.18}$$

The energy of the trial wave function is given by

$$E_k = \frac{\langle\psi_k|\,\mathcal{H}\,|\psi_k\rangle}{\langle\psi_k|\psi_k\rangle} = \frac{\sum_i\sum_j c_i^* c_j\,\langle\chi_i|\,\mathcal{H}\,|\chi_j\rangle}{\sum_i\sum_j c_i^* c_j\,\langle\chi_i|\,\chi_j\rangle}. \tag{I.19}$$

Using the rule that it suffices to vary either the state vector or its adjoint (see Section I.2) we differentiate this expression with respect to c_i^* and obtain

$$\frac{\partial E_k}{\partial c_i^*} = \frac{\left(\sum_i \sum_j c_i^* c_j\right) \sum_j c_j H_{i,j} - \left(\sum_i \sum_j c_i^* c_j H_{ij}\right) \sum_j c_j S_{ij}}{\left(\sum_{i,j} c_i^* c_j S_{ij}\right)^2} = \frac{\sum_j c_j (H_{ij} - E S_{ij})}{\sum_{i,j} c_i^* c_j S_{ij}}. \tag{I.20}$$

Here we defined

$$H_{ij} = \langle \chi_i | \mathcal{H} | \chi_j \rangle \tag{I.21}$$

as well as the quantity

$$S_{ij} = \langle \chi_i | \chi_j \rangle , \tag{I.22}$$

called the *overlap integral*. The energy E_k is stationary under variation of c_i^* when $\partial E / \partial c_i^* = 0$, which is the case for

$$\sum_j c_j (H_{ij} - E S_{i,j}) = 0. \tag{I.23}$$

Repeating this procedure for all c_i^* with $i \in \{1, \cdots, g\}$ we obtain g simultaneous equations for the g unknown variables c_j. This set of equations only has non-trivial solutions when the so-called *secular determinant* vanishes,

$$\det |H_{ij} - E S_{ij}| = 0. \tag{I.24}$$

This expression is called the *secular equation* and represents a polynomial of power g. The solutions define g energy levels, E_i with $i \in \{1, \cdots, g\}$, which are stationary with respect to small variations of the coefficients of the corresponding trial states.

I.3.1 Lifting of degeneracy by a small symmetry-breaking term

As a first special case we discuss the situation where the Hamiltonian $\mathcal{H}$ can be broken up in two hermitian parts,

$$\mathcal{H} = \mathcal{H}_0 + \mathcal{H}_1, \tag{I.25}$$

where the Schrödinger equation $\mathcal{H}_0 |\phi_i\rangle = E^0 |\phi_i\rangle$, with $i \in \{1, \cdots, g\}$, defines a g-fold degenerate manifold of levels corresponding to an orthonormal set of g eigenstates $\{|\phi_i\rangle\}$. The term $\mathcal{H}_1$ is presumed to break the symmetry and is here taken to be *small.*

Using the formalism introduced above we set $|\chi_i\rangle = |\phi_i\rangle$ and since the $\{|\phi_i\rangle\}$ are eigenstates of $\mathcal{H}_0$ we have zero overlap between different states,

$$S_{ij} = \langle \phi_i | \phi_j \rangle = \delta_{i,j}. \tag{I.26}$$

Further, we have

$$H_{i,j} = \langle \phi_i | \mathcal{H}_0 | \phi_j \rangle + \langle \phi_i | \mathcal{H}_1 | \phi_j \rangle = E^0 \delta_{ij} + \mathcal{H}'_{ij}, \tag{I.27}$$

where we defined

$$\mathcal{H}'_{i,j} = \langle \phi_i | \mathcal{H}_1 | \phi_j \rangle . \tag{I.28}$$

Substituting Eqs. (I.26) and (I.27) into the secular equation (I.24) we obtain

$$\det \left| \mathcal{H}'_{i,j} - \varepsilon_1 \delta_{i,j} \right| = 0, \tag{I.29}$$

where $\varepsilon_1 = E - E^0$. This equation has g solutions, $\varepsilon_1 = \Delta E_i$ with $i \in \{1, \cdots, g\}$, which correspond to the energy shifts of the levels E_i with respect to the degenerate value E^0,

$$E_i = E^0 + \Delta E_i \text{ with } i \in \{1, \cdots, g\}. \tag{I.30}$$

Comment: This result coincides with first-order perturbation theory for a degenerate level and is further discussed in Section H.3.

I.3.2 Variation method applied to two degenerate states

As a second special case we discuss the situation of two normalized real states $|a\rangle$ and $|b\rangle$, not necessarily orthogonal, and of the same energy.

- Because the states are degenerate we have

$$\mathcal{H}_{00} \equiv \mathcal{H}_{aa} = \langle a|\, \mathcal{H}\, |a\rangle = \langle b|\, \mathcal{H}\, |b\rangle = \mathcal{H}_{bb}. \tag{I.31}$$

- Because the states are real and $\mathcal{H}$ is hermitian

$$V \equiv \mathcal{H}_{ab} = \langle a|\, \mathcal{H}\, |b\rangle = \langle b|\, \mathcal{H}^{\dagger}\, |a\rangle^{*} = \langle b|\, \mathcal{H}\, |a\rangle = \mathcal{H}_{ba}$$

- Because the states are not necessarily orthogonal we have in general

$$S \equiv S_{ab} = \langle a|b\rangle = \langle b|a\rangle = S_{ba} \neq 0$$

In search for a state of lower energy we construct a trial state

$$|\chi\rangle = a\, |a\rangle + b\, |b\rangle\,. \tag{I.32}$$

Applying the variational principle to the coefficients a and b we obtain the secular equation

$$\begin{vmatrix} \mathcal{H}_{00} - E & V - ES \\ V - ES & \mathcal{H}_{00} - E \end{vmatrix} = 0, \tag{I.33}$$

which can be written as $(\mathcal{H}_{00} - E)^2 = (V - ES)^2$. Solving the quadratic equation yields for the eigenvalues

$$E_{\pm} = \frac{(\mathcal{H}_{00} \pm V)}{(1 \pm S)}. \tag{I.34}$$

The coefficients fixing the eigenstates are found from

$$\langle a|\, \mathcal{H}\, |\chi\rangle = E_{\pm}\, \langle a|\chi\rangle \Leftrightarrow a_{\pm}\mathcal{H}_{00} + b_{\pm}V = E_{\pm}\, (a_{\pm} + b_{\pm}S)\,, \tag{I.35}$$

which can be written as

$$\frac{a_{\pm}}{b_{\pm}} = \frac{E_{\pm}S - V}{\mathcal{H}_{00} - E_{\pm}} = \pm 1. \tag{I.36}$$

As the overlap is non-zero the normalization condition is

$$1 = \langle\chi|\chi\rangle = |a|^2 + |b|^2 + 2abS \tag{I.37}$$

Hence, setting $|a|^2 = |b|^2 = |c|^2$ we find for the coefficients

$$|c_{\pm}|^2 = \frac{1}{2(1 \pm S)}. \tag{I.38}$$

Comment: This variational method is used to calculate the exchange splitting in two-electron atoms (in this case $S = 0$). It is also the basis for the description of bonding and anti-bonding orbitals in quantum chemistry (in this case $S \neq 0$).

J

Clebsch-Gordan coefficients

J.1 Relation with the Wigner $3j$ symbols

The Clebsch-Gordan coefficients $\langle j_1m_1; j_2m_2|JM\rangle$ for the coupling $(j_1 \times j_2)$ of two quantized angular momenta $\mathbf{j}_1$ and $\mathbf{j}_2$ into the total quantized angular momentum $\mathbf{J}$ are related to the Wigner $3j$ symbols,

$$\langle j_1m_1; j_2m_2|JM\rangle \equiv (-1)^{j_1-j_2+M}\sqrt{2J+1}\begin{pmatrix} j_1 & j_2 & J \\ m_1 & m_2 & -M \end{pmatrix}, \tag{J.1}$$

where $|JM\rangle$ is a state of the coupled angular momentum and $|j_1m_1; j_2m_2\rangle \equiv |j_1m_1\rangle_1 \otimes |j_2m_2\rangle_2$ is a product state. Note that $(-1)^{j_1-j_2+M} = (-1)^{j_2-j_1-M}$ because $j_1 - j_2 + M$ is always an integer. By convention the CGCs with maximum projection of the total angular momentum are non-negative (sign convention),

$$\langle j_1j_1; j_2(J-j_1)|JJ\rangle \geq 0, \tag{J.2}$$

and unity for the stretched state (*stretched-state convention*),

$$\langle j_1j_1; j_2j_2|J_{max}J_{max}\rangle = 1, \tag{J.3}$$

where $J_{max} = j_1 + j_2$.
The Wigner $3j$ symbols can be visualized by the vector diagram shown in Fig. J.1. The properties are listed below for the $3j$ symbol $\begin{pmatrix} j_1 & j_2 & j_3 \\ m_1 & m_2 & m_3 \end{pmatrix}$:

Reality:

- $3j$ symbols are real

Selection rules:

- $3j$ symbols are zero unless the *triangle inequality* $\Delta(j_1j_2j_3)$ holds; this is the case if

$$|j_a - j_b| \leq j_c \leq j_a + j_b \tag{J.4}$$

  with a, b, c representing any cyclic permutation of $1, 2, 3$.

- $3j$ symbols are zero unless $j_1 + j_2 + j_3$ is *integral* and the angular momentum *projection is conserved*,

$$j_1 + j_2 + j_3 \in \{0, 1, \cdots\} \quad \text{and} \quad m_1 + m_2 + m_3 = 0 \tag{J.5}$$

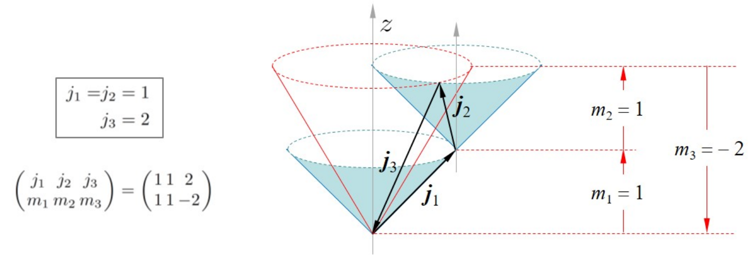

Figure J.1: To establish whether a $3j$ symbol is manifestly zero one can use a vector diagram, shown here for the example $j_1 = j_2 = 1$, $j_3 = 2$. The given $3j$ symbol is valid (*i.e.*, not manifestly zero) because the triangle is *closed* and the projections onto the z axis are quantized in integer values; hence, the triangle inequality is satisfied, $j_1 + j_2 + j_3$ is integral and the projections onto the z axis add up to zero.

Symmetries:

- invariant under cyclic permutation
- multiplied by $(-1)^{j_1+j_2+j_3}$ under interchange of two columns
- multiplied by $(-1)^{j_1+j_2+j_3}$ under simultaneous change of sign, $m_1, m_2, m_3 \to -m_1, -m_2, -m_3$

Orthogonality:

$$\sum_{m_1 m_2} (2j_3+1) \begin{pmatrix} j_1 & j_2 & j_3 \\ m_1 & m_2 & m_3 \end{pmatrix} \begin{pmatrix} j_1 & j_2 & j_3' \\ m_1 & m_2 & m_3' \end{pmatrix} = \delta_{j_3,j_3'} \delta_{m_3,m_3'} \tag{J.6}$$

$$\sum_{j_3=|j_1-j_2|}^{j_1+j_2} \sum_{m_3=-j_3}^{j_3} (2j_3+1) \begin{pmatrix} j_1 & j_2 & j_3 \\ m_1 & m_2 & m_3 \end{pmatrix} \begin{pmatrix} j_1 & j_2 & j_3 \\ m_1' & m_2' & m_3 \end{pmatrix} = \delta_{m_1,m_1'} \delta_{m_2,m_2'} \tag{J.7}$$

In particular:

$$\sum_{m_1} (2j_3+1) \begin{pmatrix} j_1 & j_2 & j_3 \\ m_1 & (m_3-m_1) & -m_3 \end{pmatrix}^2 = 1 \tag{J.8}$$

$$\sum_{J=0}^{2j} \sum_{M=-J}^{J} (2J+1) \begin{pmatrix} j & j & J \\ m_1 & m_2 & M \end{pmatrix}^2 = 1 \tag{J.9}$$

Even and odd summations:

$$\sum_{J=\text{even}}^{2j} \sum_{M=-J}^{J} (2J+1) \begin{pmatrix} j & j & J \\ m_1 & m_2 & M \end{pmatrix}^2 = \frac{1}{2} \tag{J.10a}$$

$$\sum_{J=\text{odd}}^{2j} \sum_{M=-J}^{J} (2J+1) \begin{pmatrix} j & j & J \\ m_1 & m_2 & M \end{pmatrix}^2 = \frac{1}{2} \tag{J.10b}$$

Racah formula

$$\begin{pmatrix} j_1 & j_2 & J \\ m_1 & m_2 & -M \end{pmatrix} = (-1)^{j_1-j_2+M}\sqrt{\Delta(j_1j_2J)}$$
$$\times\sqrt{(j_1+m_1)!\,(j_1-m_1)!\,(j_2+m_2)!\,(j_2-m_2)!\,(J+M)!\,(J-M)!}$$
$$\times\sum_t \frac{(-)^t}{t!(J-j_2+t+m_1)!(J-j_1+t-m_2)!(j_1+j_2-J-t)!(j_1-t-m_1)!(j_2-t+m_2)!} \tag{J.11}$$

where $t=0,1,\cdots$ and the quantity

$$\Delta(abc)\equiv\frac{(a+b-c)!(b+c-a)!(c+a-b)!}{(a+b+c+1)!} \tag{J.12}$$

offers a logical measure for the *triangle inequalities*; these are satisfied for $\Delta(j_1j_2J)>0$, whereas for $\Delta(j_1j_2J)=0$ they are violated.

J.1.1 Special cases for given values of J

- J taking its maximum value $J=j_1+j_2$

$$\begin{pmatrix} j_1 & j_2 & J \\ m_1 & m_2 & -M \end{pmatrix} = \frac{(-1)^{j_1-j_2+M}}{\sqrt{2J+1}}\sqrt{\frac{(2j_1)!(2j_2)!}{(2J)!}}\sqrt{\frac{(J+M)!\,(J-M)!}{(j_1+m_1)!\,(j_1-m_1)!\,(j_2+m_2)!\,(j_2-m_2)!}} \tag{J.13}$$

- the *stretched* case (J,M maximal); this implies $J=j_1+j_2$ and $M=J$, with $m_1=j_1$ and $m_2=j_2$,

$$\begin{pmatrix} j_1 & j_2 & j_1+j_2 \\ m_1 & m_2 & -(j_1+j_2) \end{pmatrix} = \frac{(-1)^{2j_1}}{\sqrt{2(j_1+j_2)+1}}\,\delta_{m_1,j_1}\delta_{m_2,j_2}. \tag{J.14}$$

  Since $2j_1$ is always integral, the corresponding Clebsch-Gordan coefficient is always unity,

$$\langle j_1j_1j_2j_2|(j_1+j_2)(j_1+j_2)\rangle=1. \tag{J.15}$$

- $J=0:$

$$\begin{pmatrix} j & j & 0 \\ m & -m & 0 \end{pmatrix} = (-1)^{j-m}\frac{1}{\sqrt{2j+1}} \Leftrightarrow \langle jm00|j,m\rangle=1 \tag{J.16}$$

- $J=1/2$ (note that $j+m$ is always an integer):

$$\begin{pmatrix} j & j+\frac{1}{2} & \frac{1}{2} \\ m & -m' & \pm\frac{1}{2} \end{pmatrix} = (-1)^{j-m'-1/2}\sqrt{\frac{j+1\pm m}{2\,(j+1)\,(2j+1)}}\,\delta_{m',m\pm\frac{1}{2}} \tag{J.17a}$$

$$\begin{pmatrix} j & j-\frac{1}{2} & \frac{1}{2} \\ m & -m' & \pm\frac{1}{2} \end{pmatrix} = (-1)^{j-m-1}\sqrt{\frac{j\mp m}{2j\,(2j+1)}}\,\delta_{m',m\pm\frac{1}{2}} \tag{J.17b}$$

- $J = 1$ (note that $m = 0$ can only occur for integral j and in this case $2j + 1 = \text{odd}$):

$$\begin{pmatrix} j & j & 1 \\ m & -m & 0 \end{pmatrix} = (-1)^{j-m} \frac{m}{\sqrt{j\,(j+1)\,(2j+1)}} \tag{J.18a}$$

$$\begin{pmatrix} j & j & 1 \\ m & -m' & \pm 1 \end{pmatrix} = (-1)^{j-\min(m,m')} \sqrt{\frac{j(j+1) - mm'}{2j(j+1)(2j+1)}}\, \delta_{m',m\pm 1} \tag{J.18b}$$

- $J = 2$:

$$\begin{pmatrix} j & j & 2 \\ m & -m & 0 \end{pmatrix} = (-1)^{j-m} \frac{3m^2 - j\,(j+1)}{\sqrt{j(j+1)(2j+3)\,(2j+1)\,(2j-1)}} \tag{J.19a}$$

$$\begin{pmatrix} j & j & 2 \\ m & -m' & \pm 1 \end{pmatrix} = (-1)^{j-m} \,(1 \pm 2m) \sqrt{\frac{3}{2} \frac{j(j+1) - mm'}{j(j+1)(2j+3)\,(2j+1)\,(2j-1)}}\, \delta_{m',m\pm 1} \tag{J.19b}$$

$$\begin{pmatrix} j & j & 2 \\ m & -m' & \pm 2 \end{pmatrix} = (-1)^{j-m} \sqrt{\frac{3}{2} \frac{(j^2 - 1 - mm')\,(j(j+2) - mm')}{j(j+1)(2j+3)\,(2j+1)\,(2j-1)}}\, \delta_{m',m\pm 2} \tag{J.19c}$$

- *Shell summation:*

$$\begin{pmatrix} l & k & l \\ 0 & 0 & 0 \end{pmatrix} \sum_{m=-l}^{l} (-1)^m \begin{pmatrix} l & k & l \\ -m & 0 & m \end{pmatrix} = \delta_{k,0} \tag{J.20}$$

J.1.2 Special cases for integer values of l

- $m_1 = m_2 = m_3 = 0$ and $l_1 + l_2 + l_3$ is *odd*

$$\begin{pmatrix} l_1 & l_2 & l_3 \\ 0 & 0 & 0 \end{pmatrix} = 0 \tag{J.21}$$

- $m_1 = m_2 = m_3 = 0$ and $l_1 + l_2 + l_3$ is *even* (including zero)

$$\begin{pmatrix} l_1 & l_2 & l_3 \\ 0 & 0 & 0 \end{pmatrix} = \frac{(-1)^p p! \sqrt{\Delta(l_1 l_2 l_3)}}{(p-l_1)!(p-l_2)!(p-l_3)!}, \tag{J.22}$$

where $p \equiv (l_1 + l_2 + l_3)/2$ and $\Delta(l_1 l_2 l_3)$ is given by Eq. (J.12).

- $l_3 = 0$ and $l, l' = \textit{integer}$, only nonzero if $l + l'$ is even; this implies $l' = l$ and $p \equiv (l + l')/2 = l$

$$\begin{pmatrix} l & l' & 0 \\ 0 & 0 & 0 \end{pmatrix} = (-1)^l \frac{1}{\sqrt{2l+1}}\, \delta_{l',l} \tag{J.23}$$

- $l_3 = 1$ and $l, l' = \textit{integer}$, only nonzero if $l + l' + 1$ is even; this implies $l' = l \pm 1$ and $p \equiv (l + l' + 1)/2 = \max(l, l')$

$$\begin{pmatrix} l & l' & 1 \\ 0 & 0 & 0 \end{pmatrix} = (-1)^{\max(l,l')} \sqrt{\frac{\max(l,l')}{(2l+1)(2l'+1)}}\, \delta_{l',l\pm 1} \tag{J.24}$$

- $l_3 = 2$ and $l, l' =$ *integer*, only nonzero if $l + l' + 2$ is even; this implies $l' = l,\ l \pm 2$ and $p \equiv (l + l' + 2)/2 = \max(l, l')$

$$\begin{pmatrix} l\ l'\ 2 \\ 0\ 0\ 0 \end{pmatrix} = \begin{cases} (-1)^{l+1}\sqrt{\dfrac{l\,(l+1)}{(2l+3)\,(2l+1)\,(2l-1)}} & l' = l \\ (-1)^{l}\sqrt{\dfrac{\max(l,l')}{(2l+1)(2l'+1)}\left(\dfrac{3}{4}\dfrac{l+l'}{l+l'+1}\right)} & l' = l \pm 2. \end{cases} \tag{J.25}$$

Problem J.1. Use the exchange rule for $3j$ symbols to show that the symmetry of Clebsch-Gordan coefficients under exchange of the coupled angular momenta is given by

$$\langle jm_1 j_2 m_2|JM\rangle = (-1)^{j_1+j_2-J}\langle j_2 m_2; j_1 m_1|JM\rangle.$$

Solution. The relation between the Clebsch-Gordan coefficients and the $3j$ symbols is given by

$$\langle j_1 m_1; j_2 m_2|JM\rangle \equiv (-1)^{j_1-j_2+M}\sqrt{2J+1}\begin{pmatrix} j_1 & j_2 & J \\ m_1 & m_2 & -M \end{pmatrix}.$$

Using the exchange rule for $3j$ symbols,

$$\begin{pmatrix} j_1 & j_2 & J \\ m_1 & m_2 & -M \end{pmatrix} = (-1)^{j_1+j_2+J}\begin{pmatrix} j_2 & j_1 & J \\ m_2 & m_1 & -M \end{pmatrix},$$

we find

$$\langle j_1 m_1 j_2 m_2|JM\rangle = (-1)^{3j_2-j_1+J}\langle j_2 m_2 j_1 m_1|JM\rangle.$$

Since $(-1)^{4j_2} \equiv 1$ for all allowed values of j_2, and $J - j_1 - j_2$ is always integer this results in the desired expression for exchange. □

J.2 Relation with the Wigner $6j$ symbols

The Wigner $6j$ symbols are defined by the relation

$$\langle (j_1 j_2)j_{12}, j_3; J'M'|j_1, (j_2 j_3)j_{23}; JM\rangle = (-)^{j_1+j_2+j_3+J}\sqrt{(2j_{12}+1)\,(2j_{23}+1)}\begin{Bmatrix} j_1\ j_2\ j_{12} \\ j_3\ J\ j_{23} \end{Bmatrix}\delta_{JJ'}\delta_{MM'}. \tag{J.26}$$

and can be expressed as a sum over a product of four $3j$ symbols

$$\begin{Bmatrix} j_1\ j_2\ j_3 \\ J_1\ J_2\ J_3 \end{Bmatrix} = \sum_{\substack{m_1,m_2,m_3 \\ M_1,M_2,M_3}} (-1)^{\sigma}\begin{pmatrix} j_1 & j_2 & j_3 \\ m_1 & m_2 & m_3 \end{pmatrix}\begin{pmatrix} J_2 & J_3 & j_1 \\ M_2 & -M_3 & m_1 \end{pmatrix}\begin{pmatrix} J_3 & J_1 & j_2 \\ M_3 & -M_1 & m_2 \end{pmatrix}\begin{pmatrix} J_1 & J_2 & j_3 \\ M_1 & -M_2 & m_3 \end{pmatrix} \tag{J.27}$$

where $\sigma = J_1 + J_2 + J_3 + M_1 + M_2 + M_3$.

The Wigner $6j$ symbols $\begin{Bmatrix} j_1\ j_2\ j_3 \\ J_1\ J_2\ J_3 \end{Bmatrix}$ have the following properties:

Reality:
The $6j$ symbols are all real.
Selection rules:

$$\begin{Bmatrix} j_1\ j_2\ j_3 \\ J_1\ J_2\ J_3 \end{Bmatrix} = 0 \quad \text{unless the triads } (j_1, j_2, j_3)\,(j_1, J_2, J_3)\,(J_1, j_2, J_3)\,(J_1, J_2, j_3) \tag{J.28}$$

- satisfy the triangular inequalities

- have an *integral* sum

Symmetry:

- invariant under column permutation,

$$\begin{Bmatrix} j_1 & j_2 & j_3 \\ J_1 & J_2 & J_3 \end{Bmatrix} = \begin{Bmatrix} j_2 & j_1 & j_3 \\ J_2 & J_1 & J_3 \end{Bmatrix} \tag{J.29}$$

- invariant under simultaneous exchange of two elements from the first line with the corresponding elements from the second line,

$$\begin{Bmatrix} j_1 & j_2 & j_3 \\ J_1 & J_2 & J_3 \end{Bmatrix} = \begin{Bmatrix} J_1 & J_2 & j_3 \\ j_1 & j_2 & J_3 \end{Bmatrix} \tag{J.30}$$

Orthogonality:

$$\sum_j (2j+1) \begin{Bmatrix} j_1 & j_2 & j \\ J_1 & J_2 & J \end{Bmatrix} \begin{Bmatrix} j_1 & j_2 & j \\ J_1 & J_2 & J' \end{Bmatrix} = \frac{\delta_{J'J}}{(2J+1)} \tag{J.31}$$

Special cases [36]

$$\begin{Bmatrix} j_1 & j_2 & j_3 \\ j_2 & j_1 & 0 \end{Bmatrix} = (-1)^s \frac{1}{\sqrt{(2j_1+1)(2j_2+1)}}, \tag{J.32a}$$

$$\begin{Bmatrix} j_1 & j_2 & j_3 \\ j_2 & j_1 & 1 \end{Bmatrix} = \frac{(-1)^s}{2} \frac{X}{\sqrt{j_1(j_1+1)(2j_1+1)j_2(j_2+1)(2j_2+1),}} \tag{J.32b}$$

$$\begin{Bmatrix} j_1 & j_2 & j_3 \\ j_2 & j_1 & 2 \end{Bmatrix} = \frac{(-1)^s}{2} \frac{3X\,(X+1) - 4j_1(j_1+1)j_2(j_2+1)}{\sqrt{(2j_1-1)j_1(j_1+1)(2j_1+1)(2j_1+3)(2j_2-1)j_2(j_2+1)(2j_2+1)(2j_2+3)}}, \tag{J.32c}$$

where $s = j_1 + j_2 + j_3$ and $X = j_3(j_3+1) - j_1(j_1+1) - j_2(j_2+1)$.

$$\begin{Bmatrix} j_1 & j_2 & j_3 \\ j_2-1 & j_1-1 & 1 \end{Bmatrix} = \frac{(-1)^s}{2}\sqrt{\frac{(j_1+j_2+j_3)(j_1+j_2+j_3+1)(j_1+j_2-j_3-1)(j_1+j_2-j_3)}{(2j_1-1)j_1(2j_1+1)(2j_2-1)j_2(2j_2+1)}}, \tag{J.33a}$$

$$\begin{Bmatrix} j_1 & j_2 & j_3 \\ j_2-1 & j_1 & 1 \end{Bmatrix} = \frac{(-1)^s}{2}\sqrt{\frac{(j_1+j_2+j_3+1)(j_1+j_2-j_3)(j_2+j_3-j_1)(j_1+j_3-j_2+1)}{j_1(j_1+1)(2j_1+1)(2j_2-1)j_2(2j_2+1)}}, \tag{J.33b}$$

$$\begin{Bmatrix} j_1 & j_2 & j_3 \\ j_2-1 & j_1+1 & 1 \end{Bmatrix} = \frac{(-1)^s}{2}\sqrt{\frac{(j_2+j_3-j_1-1)(j_2+j_3-j_1)(j_1+j_3-j_2+1)(j_1+j_3-j_2+2)}{(j_1+1)(2j_1+1)(2j_1+3)(2j_2-1)j_2(2j_2+1)}}. \tag{J.33c}$$

Sum rules:

- Summation over two $6j$ symbols

$$\sum_{J''}(-1)^{J+J'+J''}(2J''+1)\begin{Bmatrix} j_1 & j_2 & J \\ j_3 & j & J'' \end{Bmatrix}\begin{Bmatrix} j_2 & j_3 & J'' \\ j_1 & j & J' \end{Bmatrix} = \begin{Bmatrix} j_3 & j_1 & J' \\ j_2 & j & J \end{Bmatrix} \tag{J.34}$$

- summation over product of four $3j$ symbols

$$\sum_{q}\sum_{\substack{m_1 m_2 \\ m_1', m_2'}}(-1)^{\sigma}\begin{pmatrix} j_1 & j_2 & J \\ m_1 & m_2 & M \end{pmatrix}\begin{pmatrix} j_2' & j_1' & J' \\ m_2' & m_1' & M' \end{pmatrix}\begin{pmatrix} j_1 & j_1' & k \\ -m_1 & m_1' & q \end{pmatrix}\begin{pmatrix} j_2 & j_2' & k \\ -m_2 & -m_2' & q \end{pmatrix} =$$

$$= \delta_{J,J'}\delta_{M,M'}\frac{1}{2J+1}\begin{Bmatrix} j_1 & j_2 & J \\ j_2' & j_1' & k \end{Bmatrix}, \tag{J.35}$$

where $\sigma = j_1' + j_2' + J + m_1 + m_2 + q$.

- summation over the product of three $3j$ symbols

$$\sum_{m_1 m_2 m_3}(-1)^{\sigma}\begin{pmatrix} j_1 & j_2 & j \\ m_1 & -m_2 & m \end{pmatrix}\begin{pmatrix} j_2 & j_3 & j' \\ m_2 & -m_3 & m' \end{pmatrix}\begin{pmatrix} j_3 & j_1 & J \\ m_3 & -m_1 & M \end{pmatrix} =$$

$$= \begin{Bmatrix} j' & J & j \\ j_1 & j_2 & j_3 \end{Bmatrix}\begin{pmatrix} j' & J & j \\ m' & M & m \end{pmatrix}, \tag{J.36}$$

where $\sigma = j_1 + j_2 + j_3 + m_1 + m_2 + m_3$. Note that $m_1 = m_2 - m$ and $m_3 = m_2 + m'$; *i.e.*, the sum runs over a single independent index (m_2).

- summation over product of two $3j$ symbols

$$\sum_{m}(-1)^{j+m}\begin{pmatrix} j_1 & j_2 & j \\ m_1 & m_2 & -m \end{pmatrix}\begin{pmatrix} j_1' & j_2' & j \\ m_1' & m_2' & m \end{pmatrix}$$

$$= (-1)^{-j_2-j_1'-j-J}\sum_{J,M}(-1)^{J+M}(2J+1)\begin{Bmatrix} j_1 & j_1' & J \\ j_2' & j_2 & j \end{Bmatrix}\begin{pmatrix} j_1 & j_1' & J \\ m_1 & m_1' & -M \end{pmatrix}\begin{pmatrix} j_2 & j_2' & J \\ m_2 & m_2' & M \end{pmatrix} \tag{J.37}$$

Note that $M = m_1 + m_1' = -m_2 - m_2'$ and $m = m_1 + m_2 = -m_1' - m_2'$; *i.e.*, the summations over m and M both consist only of a single nonzero term.

J.2.0.1 Determination of Clebsch-Gordan coefficients - recursion relations

The values of the Clebsch-Gordan coefficients can be determined using recursion relations. In this section we derive two of such relations. Their use is demonstrated in Problem J.2. As you will see the procedure is labor intensive. Therefore, it makes little sense to rederive these values every time we need them. Once we understand the procedure, it suffices to determine the values with *Mathematica*. For reference purposes some old-fashioned look-up tables are included in Appendix J. These are derived from the vector sum identity (3.83). For more information the books *Elementary theory of Angular Momentum* by Morris Rose [94] and *Angular Momentum in Quantum Mechanics* by A.R. Edmonds [36] are highly recommended.

- $\Delta J = 0;\ \Delta M = +1$: To relate the Clebsch-Gordan coefficient $\langle j_1 m_1; j_2 m_2 | J(M-1)\rangle$ with coefficients in which M is *raised* by one unit of angular momentum we use the operator identity $J_- = j_{1-} + j_{2-}$ and start from the equation

$$\langle j_1 m_1; j_2 m_2 | J_- | JM\rangle = \langle j_1 m_1; j_2 m_2 | j_{1-} + j_{2-} | JM\rangle . \tag{J.38}$$

As the raising and lowering operators are hermitian conjugates we obtain a recursion *relation* for Clebsch-Gordan coefficients

$$\begin{aligned}\sqrt{J(J+1) - M(M-1)}\langle j_1 m_1; j_2 m_2 | J(M-1)\rangle = \\ = \sqrt{j_1(j_1+1) - m_1(m_1+1)}\langle j_1(m_1+1); j_2 m_2 | JM\rangle \\ + \sqrt{j_2(j_2+1) - m_2(m_2+1)}\langle j_1 m_1; j_2(m_2+1) | JM\rangle .\end{aligned} \tag{J.39}$$

Specializing to the case $M = J$ and $m_1 = j_1$, the selection rule (3.89) implies $m_2 = J - j_1 - 1$ and the recursion relation simplifies to

$$\langle j_1 j_1; j_2(J - j_1 - 1) | J(J-1)\rangle = \sqrt{\frac{j_2(j_2+1) - (J - j_1 - 1)(J - j_1)}{2J}}\langle j_1 j_1; j_2(J - j_1) | JJ\rangle . \tag{J.40}$$

- $\Delta J = 0;\ \Delta M = -1$: To relate the Clebsch-Gordan coefficient $\langle j_1 m_1; j_2 m_2 | J(M+1)\rangle$ with coefficients in which M is *lowered* by one unit of angular momentum we use the operator identity $J_+ = j_{1+} + j_{2+}$ and start from the equation

$$\langle j_1 m_1; j_2 m_2 | J_+ | J(M-1)\rangle = \langle j_1 m_1; j_2 m_2 | j_{1+} + j_{2+} | J(M-1)\rangle . \tag{J.41}$$

As the raising and lowering operators are hermitian conjugates we obtain the recursion relation

$$\begin{aligned}\sqrt{J(J+1) - M(M+1)}\langle j_1 m_1; j_2 m_2 | J(M+1)\rangle = \\ = \sqrt{j_1(j_1+1) - m_1(m_1-1)}\langle j_1(m_1-1); j_2 m_2 | JM\rangle \\ + \sqrt{j_2(j_2+1) - m_2(m_2-1)}\langle j_1 m_1; j_2(m_2-1) | JM\rangle .\end{aligned} \tag{J.42}$$

Specializing to the case $M = J - 1$ and $m_1 = j_1$, the selection rule (3.89) implies $m_2 = J - j_1$ and the recursion relation becomes

$$\begin{aligned}\sqrt{2J}\langle j_1 j_1; j_2(J - j_1) | JJ\rangle = \sqrt{2j_1}\langle j_1(j_1 - 1); j_2(J - j_1) | J(J-1)\rangle \\ + \sqrt{j_2(j_2+1) - (J - j_1)(J - j_1 - 1)}\langle j_1 j_1; j_2(J - j_1 - 1) | J(J-1)\rangle .\end{aligned} \tag{J.43}$$

Substituting Eq. (J.40) we find an expression for the next Clebsch-Gordan coefficient,

$$\langle j_1(j_1-1); j_2(J-j_1) | J(J-1)\rangle = \frac{2J - j_2(j_2+1) + (J - j_1)(J - j_1 - 1)}{2\sqrt{j_1 J}}\langle j_1 j_1; j_2(J-j_1) | JJ\rangle . \tag{J.44}$$

Table J.1: Clebsch-Gordan coefficients for coupling of the angular momenta $j_1 = \frac{3}{2}$ and $j_2 = \frac{1}{2}$. Only the non-zero coefficients are indicated. Note the selection rule $M = m_1 + m_2$.

$\langle j_1 j_2, m_1, m_2 \vert JM\rangle$	$\vert 2,+2\rangle$	$\vert 2,+1\rangle$	$\vert 1,+1\rangle$	$\vert 2,0\rangle$	$\vert 1,0\rangle$	$\vert 1,-1\rangle$	$\vert 2,-1\rangle$	$\vert 2,-2\rangle$
$(j_1 j_2, +\frac{3}{2}, +\frac{1}{2}\vert$	1							
$(j_1 j_2, +\frac{3}{2}, -\frac{1}{2}\vert$		$\sqrt{1/4}$	$\sqrt{3/4}$					
$(j_1 j_2, +\frac{1}{2}, +\frac{1}{2}\vert$		$\sqrt{3/4}$	$-\sqrt{1/4}$					
$(j_1 j_2, +\frac{1}{2}, -\frac{1}{2}\vert$				$\sqrt{1/2}$	$\sqrt{1/2}$			
$(j_1 j_2, -\frac{1}{2}, +\frac{1}{2}\vert$				$\sqrt{1/2}$	$-\sqrt{1/2}$			
$(j_1 j_2, -\frac{1}{2}, -\frac{1}{2}\vert$						$\sqrt{1/4}$	$\sqrt{3/4}$	
$(j_1 j_2, -\frac{3}{2}, +\frac{1}{2}\vert$						$-\sqrt{3/4}$	$\sqrt{1/4}$	
$(j_1 j_2, -\frac{3}{2}, -\frac{1}{2}\vert$								1
$M = m_1 + m_2$	2	1		0		-1		-2

With these recursion relations it is possible to express Clebsch-Gordan coefficients in terms of the "stretched" coefficient $\langle j_1 j_1; j_2(J-j_1)\,|JJ\rangle$, which is positive by convention. The procedure is demonstrated in Problem J.2. An example of a complete Clebsch-Gordan table for the addition of $j_1 = 3/2$ and $j_2 = 1/2$ is given in Table J.1.

J.2.0.2 Example: Spin-doublet system with half-integral total angular momentum

The case of coupling a spin $s = \frac{1}{2}$ to orbital angular momentum l is special since only two J values can emerge, $j = l \pm \frac{1}{2}$. This implies that j and m_J have half-integral values. Using the m_J selection rule (3.89) the Clebsch-Gordan decomposition (3.106) reduces to two terms,

$$|(l \pm \tfrac{1}{2}), m_J\rangle = \sum_{m_s=+1/2}^{-1/2} |l(m_J - m_s), sm_s\rangle (l(m_J - m_s), sm_s|(l \pm \tfrac{1}{2}), m_J\rangle. \tag{J.45}$$

This expression can be written in the form

$$|(l + \tfrac{1}{2}), m_J\rangle = a_+ |l(m_J - m_s); \tfrac{1}{2}, \tfrac{1}{2}\rangle + a_- |l(m_J - m_s); \tfrac{1}{2}, -\tfrac{1}{2}\rangle \tag{J.46}$$

$$|(l - \tfrac{1}{2}), m_J\rangle = b_+ |l(m_J - m_s); \tfrac{1}{2}, \tfrac{1}{2}\rangle + b_- |l(m_J - m_s); \tfrac{1}{2}, -\tfrac{1}{2}\rangle. \tag{J.47}$$

where the Clebsch-Gordan coefficients,

$$\begin{aligned} a_\pm &= (l(m_J \mp \tfrac{1}{2}); \tfrac{1}{2}, \pm\tfrac{1}{2}|(l + \tfrac{1}{2}), m_J\rangle \\ &= (-)^{-(1/2-l-m_J)} \sqrt{2(l+1)} \begin{pmatrix} l & 1/2 & l + 1/2 \\ m_J \mp 1/2 & \pm 1/2 & -m_J \end{pmatrix} = \sqrt{\frac{l + 1/2 \pm m_J}{(2l+1)}} \end{aligned} \tag{J.48}$$

$$\begin{aligned} b_\pm &= (l(m_J \mp \tfrac{1}{2}); \tfrac{1}{2}, \pm\tfrac{1}{2}|(l - \tfrac{1}{2}), m_J\rangle \\ &= (-)^{-(1/2-l-m_J)} \sqrt{2l} \begin{pmatrix} l & 1/2 & l - 1/2 \\ m_J \mp 1/2 & \pm 1/2 & -m_J \end{pmatrix} = \mp\sqrt{\frac{l + 1/2 \mp m_J}{(2l+1)}}. \end{aligned} \tag{J.49}$$

are readily determined with the aid of Eqs. (J.17a) and (J.17b).

It is important to understand this *spin-doublet system* also from a more general point of view. As the states $|(l + \frac{1}{2}), m_J\rangle$ and $|(l - \frac{1}{2}), m_J\rangle$ form an orthonormal pair, the coefficients must satisfy the normalization condition

$$a_\pm^2 + a_\mp^2 = 1 \tag{J.50}$$

as well as the orthogonality condition

$$a_+b_+ + a_-b_- = 0. \tag{J.51}$$

Note that both conditions are satisfied if we define an angle $0 \leq \alpha \leq \pi/2$ such that $a_+ = \cos\alpha$, $b_+ = \sin\alpha$ and $a_- = -\sin\alpha$, $b_- = \cos\alpha$. Note that $b_\pm = \mp a_\mp$, which implies

$$a_\pm^2 + b_\pm^2 = 1. \tag{J.52}$$

The angle α is called the coupling angle. This choice of phases for the coefficients is in accordance with the *Condon and Shortly phase convention* for this two-level system of an angular momenta l and s,

$$|(l+\tfrac{1}{2}), m_J\rangle = +\cos\alpha|l(m_J - m_s), \uparrow\rangle + \sin\alpha|l(m_J - m_s), \downarrow\rangle \tag{J.53}$$

$$|(l-\tfrac{1}{2}), m_J\rangle = -\sin\alpha|l(m_J - m_s), \uparrow\rangle + \cos\alpha|l(m_J - m_s), \downarrow\rangle. \tag{J.54}$$

In this convention the coefficients of the state of maximal J (parallel coupling) are chosen to be positive.

Problem J.2. Derive the Clebsch-Gordan coefficients for coupling of the angular momenta $j_1 = \frac{3}{2}$ and $j_2 = \frac{1}{2}$ (see Table J.1). Note that this is an example of a doublet system with integral total angular momentum.

Solution. First the case $J = 2$. We start from the *stretched state convention*,

$$(\tfrac{3}{2}\tfrac{3}{2}; \tfrac{1}{2}\tfrac{1}{2}\,|22\rangle = 1. \tag{a}$$

Applying Eq. (J.40) we obtain

$$(\tfrac{3}{2}\tfrac{3}{2}; \tfrac{1}{2} - \tfrac{1}{2}\,|21\rangle = \tfrac{1}{2}. \tag{b}$$

Next we use the recursion relation (J.42) with the values $m_1 = \frac{3}{2}$, $m_2 = \frac{1}{2}$ and $M = 1$. Substituting (a) and (b) we find

$$2\,(\tfrac{3}{2}\tfrac{3}{2}; \tfrac{1}{2}\tfrac{1}{2}\,|22\rangle = \sqrt{3}\,(\tfrac{3}{2}\tfrac{1}{2}; \tfrac{1}{2}\tfrac{1}{2}\,|21\rangle + (\tfrac{3}{2}\tfrac{3}{2}; \tfrac{1}{2} - \tfrac{1}{2}\,|21\rangle \Rightarrow (\tfrac{3}{2}\tfrac{1}{2}; \tfrac{1}{2}\tfrac{1}{2}\,|21\rangle = \sqrt{3/4}. \tag{c}$$

Next we use the recursion relation (J.42) with the values $m_1 = \frac{3}{2}$, $m_2 = -\frac{1}{2}$ and $M = 0$. Substituting (b) and (c) we find

$$\sqrt{6}\,(\tfrac{3}{2}\tfrac{3}{2}; \tfrac{1}{2} - \tfrac{1}{2}\,|21\rangle = \sqrt{3}\,(\tfrac{3}{2}\tfrac{1}{2}; \tfrac{1}{2} - \tfrac{1}{2}\,|20\rangle \Rightarrow (\tfrac{3}{2}\tfrac{1}{2}; \tfrac{1}{2} - \tfrac{1}{2}\,|20\rangle = \sqrt{1/2}. \tag{d}$$

Next we use the recursion relation (J.42) with the values $m_1 = \frac{3}{2}$, $m_2 = \frac{1}{2}$ and $M = 0$. Substituting (c) and (d) we find

$$\sqrt{6}\,(\tfrac{3}{2}\tfrac{1}{2}; \tfrac{1}{2}\tfrac{1}{2}\,|21\rangle = 2\,(\tfrac{3}{2} - \tfrac{1}{2}; \tfrac{1}{2}\tfrac{1}{2}\,|20\rangle + (\tfrac{3}{2}\tfrac{1}{2}; \tfrac{1}{2} - \tfrac{1}{2}\,|20\rangle \Rightarrow (\tfrac{3}{2} - \tfrac{1}{2}; \tfrac{1}{2}\tfrac{1}{2}\,|20\rangle = \sqrt{1/2}.$$

Continuing this procedure we obtain all Clebsch-Gordan coefficients for $J = 2$.

We turn to the case $J = 1$. In this case we have no stretched state, so we have to determine the starting value in a different way. We start with the recursion relation (J.42) with the values $m_1 = \frac{3}{2}$, $m_2 = \frac{1}{2}$ and $M = 1$,

$$0 = \sqrt{3}\,(\tfrac{3}{2}\tfrac{1}{2}; \tfrac{1}{2}\tfrac{1}{2}\,|11\rangle + (\tfrac{3}{2}\tfrac{3}{2}; \tfrac{1}{2} - \tfrac{1}{2}\,|11\rangle \Rightarrow (\tfrac{3}{2}\tfrac{1}{2}; \tfrac{1}{2}\tfrac{1}{2}\,|11\rangle = -\sqrt{1/3}\,(\tfrac{3}{2}\tfrac{3}{2}; \tfrac{1}{2} - \tfrac{1}{2}\,|11\rangle\,. \tag{e}$$

Using the orthonormality relation

$$|(\tfrac{3}{2}\tfrac{1}{2}; \tfrac{1}{2}\tfrac{1}{2}\,|11\rangle\,|^2 + |(\tfrac{3}{2}\tfrac{3}{2}; \tfrac{1}{2} - \tfrac{1}{2}\,|11\rangle\,|^2 = 1$$

we find, using Eq. (e) and the *sign convention*,

$$(\tfrac{3}{2}\tfrac{3}{2}; \tfrac{1}{2} - \tfrac{1}{2}\,|11\rangle = \sqrt{3/4} \text{ and } (\tfrac{3}{2}\tfrac{1}{2}; \tfrac{1}{2}\tfrac{1}{2}\,|11\rangle = -\sqrt{1/4}.$$

From here on we can continue with the recursion procedure as discussed for $J = 2$ until all values are determined. □

J.2.1 Tables of Clebsch-Gordan coefficients

Table J.2: The Clebsch-Gordan coefficients $\langle j_1 j_2 m_1 m_2 | jm\rangle$ for the coupling of two angular momenta $\mathbf{j}_1$ and $\mathbf{j}_2$ to the total angular momentum $\mathbf{J} = \mathbf{j}_1 + \mathbf{j}_2$ for the cases $(j_1 \times j_2) = (\frac{1}{2} \times \frac{1}{2})$, $(1 \times \frac{1}{2})$, $(\frac{3}{2} \times \frac{1}{2})$, $(2 \times \frac{1}{2})$.

K

Irreducible tensor operators

K.1 Definition

An *irreducible tensor operator* of rank k, denoted by $\mathrm{T}^{(k)}$, is defined as a set of $2k+1$ components, $T_{k,q} \in \{T_{k,-k}, \cdots, T_{k,k}\}$, which transform according to the $(2k+1)$-dimensional representation $\mathscr{D}^k_{q'q}(\alpha,\beta,\gamma)$ of the full rotation group (see Section 3.9.4),

$$T'_{kq} = P_R T_{kq} P_R^\dagger = \sum_{q'=-k}^{+k} T_{kq'} \mathscr{D}^k_{q'q}, \tag{K.1}$$

where

$$P_R \equiv P(\alpha,\beta,\gamma) = P_z(\alpha)P_y(\beta)P_z(\gamma) = e^{-i\alpha J_z/\hbar} e^{-i\beta J_y/\hbar} e^{-i\gamma J_z/\hbar}. \tag{K.2}$$

is the operator for a rotation of the physical system over the Euler angles α,β,γ (see Section 3.9.3). The components $T_{k,q}$ act in a $(2k+1)$-dimensional subspace of the basis $\{|\alpha JM\rangle\}$ of the standard representation $\{J^2, J_z\}$. The symbol α points to all other (including non-angular momentum) quantum numbers of the system. Alternatively, irreducible tensor operators can be defined by the following commutation relations of their standard components (see Problem K.1) [86],

$$[J_z, T_{k,q}] = q\,\hbar\,T_{k,q} \tag{K.3a}$$

$$[J_\pm, T_{k,q}] = \sqrt{(k \mp q)\,(k \pm q + 1)}\,\hbar\,T_{k,q\pm1} = \sqrt{k\,(k+1) - q\,(q \pm 1)}\,\hbar\,T_{k,q\pm1}. \tag{K.3b}$$

The $T_{k,q}$ of *integral* rank are called *spherical tensor* operators [93] because they transform like the spherical harmonics $Y_k^q(\hat{\mathbf{r}})$. For this reason the hermitian conjugate of $T_{k,q}$ is given by

$$T^\dagger_{k,q} = (-1)^q T_{k,-q} \text{ for } k = 0,1,2,\cdots. \tag{K.4}$$

This can be verified with the aid of the commutation relations (K.3).

Problem K.1. Derive the commutation relations K.3 from the transformation properties K.1

Solution. To deal with J_a we consider an infinitesimal rotation $\delta\varphi$ about the direction $\hat{\mathbf{a}}$,

$$P_a(\delta\varphi)T_{k,q}P_a^\dagger(\delta\varphi) = \sum_{q'} T_{k,q'}\langle k,q'|P_a(\delta\phi)|k,q\rangle.$$

Using Eq. (3.217) we have $P_R \to P_a(\delta\varphi) = 1 - i\delta\varphi J_a/\hbar$ and the l.h.s. becomes

$$P_a(\delta\varphi)T_{k,q}P_a^\dagger(\delta\varphi) = T_{k,q} - \frac{i}{\hbar}\delta\varphi J_a T_{k,q} + \frac{i}{\hbar}\delta\varphi T_{k,q}J_a + \frac{1}{\hbar^2}(\delta\varphi)^2 J_a T_{k,q} J_a.$$

On the r.h.s. the rotation matrix becomes

$$\langle k,q'|P_a(\delta\phi)|k,q\rangle = \delta_{q,q'} - \frac{i}{\hbar}\delta\varphi\langle k,q'|J_a|k,q\rangle.$$

Thus we obtain

$$T_{k,q} - \frac{i}{\hbar}\delta\varphi J_a T_{k,q} + \frac{i}{\hbar}\delta\varphi T_{k,q}J_a + \frac{1}{\hbar^2}(\delta\varphi)^2 J_a T_{k,q} J_a = T_{k,q} - \frac{i}{\hbar}\delta\varphi\sum_{q'}\langle k,q'|J_a|k,q\rangle.$$

Subtracting $T_{k,q}$ from both sides and dividing by $i\delta\varphi/\hbar$ this expression reduces in the limit $\delta\varphi\to 0$ to the form

$$[J_a, T_{k,q}] = \sum_{q'}\langle k,q'|J_a|k,q\rangle T_{k,q}.$$

In particular, this holds for $\hat{\mathbf{a}}\to\hat{\mathbf{x}}$, $\hat{\mathbf{a}}\to\hat{\mathbf{y}}$ and $\hat{\mathbf{a}}\to\hat{\mathbf{z}}$. For $\hat{\mathbf{a}}\to\hat{\mathbf{z}}$ the sum reduces to

$$[J_z, T_{k,q}] = q\,\hbar\, T_{k,q}.$$

Since $J_\pm = J_x \pm iJ_y$ we find

$$[J_\pm, T_{k,q}] = \sqrt{k\,(k+1) - q\,(q\pm1)}\,\hbar\, T_{k,q\pm1}. \qquad \square$$

K.1.1 Spherical tensor operators of rank zero - scalar operators

The simplest class of irreducible tensor operators are scalar operators $T_{0,0}$. These are irreducible tensor operator of rank 0; *i.e.*, $k=0$ and $q=0$, which means that scalar operators only have a single component. Any operator that commutes with J_+, J_- and J_z is a scalar operator in the vector space spanned by the basis $\{|\alpha JM\rangle\}$,

$$[J_z, T_{0,0}] = 0 \tag{K.5a}$$

$$[J_\pm, T_{0,0}] = 0. \tag{K.5b}$$

In other words, scalar operators are invariant under arbitrary rotations of the vector space in which they operate. An example of a scalar operator is the operator $\mathbf{L}^2$ in the vector space $\{|LM\rangle\}$. Operators like p_r and r or any function $f(r)$ of r are scalar operators within the vector space $\{|nlm\rangle\}$ of hydrogenic atoms with only principal structure.

K.1.2 Spherical tensor operators of rank 1 - vector operators

Vector operators are defined as operators with the same transformation properties as the radius vector $\mathbf{r}$ under proper rotations; *i.e.*, rotations in which the handedness of the coordinate system is conserved. In the *cartesian basis* an arbitrary real vector operator $\mathbf{T}$ can be written as

$$\mathbf{T} = \hat{\mathbf{x}}T_x + \hat{\mathbf{y}}T_y + \hat{\mathbf{z}}T_z \Leftrightarrow \begin{pmatrix} T_x \\ T_y \\ T_z \end{pmatrix}, \tag{K.6}$$

where T_x, T_y, T_z are called the cartesian components. Vector operators can be expressed as irreducible tensor operators of rank 1; i.e., $k=1$ and $q=0,\pm1$ and we write $\mathbf{T}$ for $\mathrm{T}^{(1)}$. In the standard phase convention (*Condon and Shortley*) the *standard components* of $\mathbf{T}$ are given by s

$$T_{1,0} = T_z, \qquad T_{1,\pm1} = \mp\sqrt{\tfrac{1}{2}}(T_x \pm iT_y). \tag{K.7}$$

Substituting the inverse relations

$$T_x = -\sqrt{\tfrac{1}{2}}(T_{1,+1} - T_{1,-1}) \quad \text{and} \quad T_y = i\sqrt{\tfrac{1}{2}}(T_{1,+1} + T_{1,-1}) \tag{K.8}$$

into Eq. (K.6) the standard decomposition takes the form

$$\mathbf{T} = \hat{\mathbf{u}}_{+1}^{*} T_{1,+1} + \hat{\mathbf{u}}_{0} T_{1,0} + \hat{\mathbf{u}}_{-1}^{*} T_{1,-1}, \tag{K.9}$$

where the $\hat{\mathbf{u}}_q$, with $q = 0, \pm 1$, are the *spherical* unit vectors

$$\hat{\mathbf{u}}_{+1} = -\sqrt{\tfrac{1}{2}}(\hat{\mathbf{x}} + i\hat{\mathbf{y}}), \qquad \hat{\mathbf{u}}_{-1} = +\sqrt{\tfrac{1}{2}}(\hat{\mathbf{x}} - i\hat{\mathbf{y}}), \qquad \hat{\mathbf{u}}_{0} = \hat{\mathbf{z}}. \tag{K.10}$$

The commutation relations (K.3) become

$$\begin{aligned} [J_z, T_{1,0}] &= 0 & [J_z, T_{1,\pm 1}] &= \pm\hbar\, T_{1,\pm 1} \\ [J_\pm, T_{1,0}] &= \sqrt{2}\,\hbar\, T_{1,\pm 1} & [J_\pm, T_{1,\mp 1}] &= \sqrt{2}\,\hbar\, T_{1,0}. \end{aligned} \tag{K.11}$$

In particular, the *standard components* J_{+1}, J_0, J_{-1} of the angular momentum operator $\mathbf{J}$ are defined as

$$J_0 = J_z; \qquad J_{\pm 1} = \mp\sqrt{\tfrac{1}{2}}(J_x \pm iJ_y) = \mp\sqrt{\tfrac{1}{2}}J_\pm. \tag{K.12}$$

Using these relations the commutations take the form

$$\begin{aligned} [T_{1,0}, T_{1,0}] &= 0 & [T_{1,0}, T_{1,\pm 1}] &= \pm\hbar\, T_{1,\pm 1} \\ [T_{1,\pm 1}, T_{1,0}] &= \mp\hbar\, T_{1,\pm 1} & [T_{1,\pm 1}, T_{1,\mp 1}] &= \mp\hbar\, T_{1,0}. \end{aligned} \tag{K.13}$$

Example K.1. The simplest example of a vector operator is the radius vector *operator* $\underline{\mathbf{r}}$ with cartesian components $\underline{x}, \underline{y}, \underline{z}$ and standard components

$$T_{1,0} = \underline{z}, \qquad T_{1,\pm 1} = \mp\sqrt{\tfrac{1}{2}}(\underline{x} \pm i\underline{y}), \tag{K.14}$$

which can be rewritten in the form

$$T_{1,0} = \underline{r}\cos\underline{\theta} = \sqrt{4\pi/3}\,\underline{r}Y_1^0(\hat{\underline{\mathbf{r}}}), \tag{K.15a}$$

$$T_{1,\pm 1} = \mp\sqrt{\tfrac{1}{2}}\,\underline{r}(\sin\underline{\theta}\cos\underline{\phi} \pm i\sin\underline{\theta}\sin\underline{\phi}) = \sqrt{4\pi/3}\,\underline{r}Y_1^{\pm 1}(\hat{\underline{\mathbf{r}}}), \tag{K.15b}$$

where $\underline{r} = |\underline{\mathbf{r}}|$ and $\hat{\underline{\mathbf{r}}}$ is the operator for the direction unit vector. Note that these standard components transform like the spherical harmonics,

$$T_{1,m} = \sqrt{4\pi/3}\,\underline{r}Y_1^m(\hat{\underline{\mathbf{r}}}). \tag{K.16}$$

Substituting these quantities into the commutation relations (K.11) we find

$$\begin{aligned} [L_z, Y_1^0(\hat{\underline{\mathbf{r}}})] &= 0 & [L_z, Y_1^{\pm 1}(\hat{\underline{\mathbf{r}}})] &= \pm\hbar Y_1^{\pm 1}(\hat{\underline{\mathbf{r}}}) \\ [L_\pm, Y_1^0(\hat{\underline{\mathbf{r}}})] &= \sqrt{2}\hbar Y_1^{\pm 1}(\hat{\underline{\mathbf{r}}}) & [L_\pm, Y_1^{\mp 1}(\hat{\underline{\mathbf{r}}})] &= \sqrt{2}\hbar Y_1^0(\hat{\underline{\mathbf{r}}}). \end{aligned} \tag{K.17}$$

Using the relations (1.53) and (1.55) we readily verify (with the aid of a test function) that these commutation relations are indeed satisfied.[1]

Example K.2. A second example of an irreducible vector operator is the angular momentum operator $\mathbf{L}$, which acts in the vector space spanned by the basis $\{|LM\rangle\}$ of the standard representation $\{L^2, L_Z\}$. The operator $\mathbf{L}$ is a (pseudo) vector with cartesian components L_x, L_y, L_z and standard components

$$T_{1,0} = L_z, \qquad T_{1,\pm 1} = \mp\sqrt{\tfrac{1}{2}}(L_x \pm iL_y) = \mp\sqrt{\tfrac{1}{2}}L_\pm. \tag{K.18}$$

Substituting these definitions into the commutation relations (K.11) we find

$$\begin{aligned} [L_z, L_z] &= 0 & [L_z, L_\pm] &= \pm\hbar L_\pm \\ [L_\pm, L_z] &= \mp\hbar L_\pm & [L_\pm, L_\mp] &= \pm 2\hbar L_z, \end{aligned} \tag{K.19}$$

which coincide with the commutation relations derived in Chapter 1, as it should be.

---

[1] Note that a test function $\varphi(\mathbf{r})$ is a function of $\mathbf{r} = \{x, y, z\}$. The operator $\underline{\mathbf{r}}$ acting on this test function yields the variable $\mathbf{r}$.

K.1.3 Generalization - spherical tensor operators of rank 2

We now generalize the vector concept by introducing tensors in the cartesian space. The simplest tensor is a tensor of rank 0. This is a quantity which is invariant under proper rotations about the origin of the cartesian space. A tensor of rank 1 is a quantity with the same transformation properties under proper rotations as the fundamental vector

$$\mathbf{r} = \hat{\mathbf{x}}x + \hat{\mathbf{y}}y + \hat{\mathbf{z}}z \Leftrightarrow \begin{pmatrix} x \\ y \\ z \end{pmatrix}, \tag{K.20}$$

where $\hat{\mathbf{u}} = \partial_u \mathbf{r}$, with $u \in \{x, y, z\}$. A tensor of rank 2 is defined as a quantity with the same transformation properties under proper rotations as the fundamental tensor

$$\overleftrightarrow{\mathbf{r}} = \hat{\mathbf{x}}\hat{\mathbf{x}}xx + \hat{\mathbf{x}}\hat{\mathbf{y}}xy + \hat{\mathbf{x}}\hat{\mathbf{z}}xz + \hat{\mathbf{y}}\hat{\mathbf{x}}yx + \hat{\mathbf{y}}\hat{\mathbf{y}}yy + \hat{\mathbf{y}}\hat{\mathbf{z}}yz + \hat{\mathbf{z}}\hat{\mathbf{x}}zx + \hat{\mathbf{z}}\hat{\mathbf{y}}zy + \hat{\mathbf{z}}\hat{\mathbf{z}}zz \Leftrightarrow \begin{pmatrix} xx\;xy\;xz \\ yx\;yy\;yz \\ zx\;zy\;zz \end{pmatrix}, \tag{K.21}$$

where $\hat{\mathbf{u}}\hat{\mathbf{v}} = \partial_{uv}\overleftrightarrow{\mathbf{r}}$, with $u, v \in \{x, y, z\}$. It is straightforward to generalize this concept and define tensors of higher rank.

K.2 Wigner-Eckart theorem

Let $T_{k,q}$ be the standard components of an irreducible tensor operator in the angular momentum vector space defined by the standard representation $\{J^2, J_z\}$. The Wigner-Eckart theorem states that any matrix element of $T_{k,q}$ in this representation can be reduced to the form

$$\langle J'M'|T_{k,q}|JM\rangle = \frac{1}{\sqrt{2J'+1}}\langle J'||T_k||J\rangle(JM;kq|J'M'\rangle, \tag{K.22}$$

where $(JM, kq|J'M'\rangle$ is a Clebsch-Gordan coefficient and the factor $\langle J'||T_k||J\rangle$ stands for all properties of the matrix element that do not depend on M, M' and q. This factor is called the *reduced matrix element* of the tensor for given values of J and J'. In a way, the notation $\langle J'||T_k||J\rangle$ suggests more than it actually delivers because it only points to the *existence* of such a factor.[1] Its value has to be determined on a case by case basis by explicit calculation of one of the matrix elements $\langle J'M'|T_{k,q}|JM\rangle$. Importantly, since $\langle J'||T_k||J\rangle$ is independent of M, M' and q we can use the most convenient matrix element for this purpose. Some key examples are given in Section K.3.

In terms of $3j$ symbols, the theorem takes the form

$$\langle J'M'|T_{k,q}|JM\rangle = (-1)^{J-k+M'}\langle J'||T_k||J\rangle \begin{pmatrix} J & k & J' \\ M & q & -M' \end{pmatrix}. \tag{K.23}$$

This form is best suited for rearranging the quantum numbers (taking advantage of the convenient symmetry properties of the $3j$ symbols). For *integral* k the expression is equivalent to

$$\langle J'M'|T_{k,q}|JM\rangle = (-1)^{J'-M'}\langle J'||T_k||J\rangle \begin{pmatrix} J' & k & J \\ -M' & q & M \end{pmatrix}. \tag{K.24}$$

To arrive at this result we used the permutation rule for $3j$ symbols. Furthermore, since $J' + M'$ is always integral, we have $(-1)^{J'+M'} = (-1)^{-J'-M'}$. As k was taken to be integral also $J - J'$ is

---

[1] The presence of the prefactor $1/\sqrt{2J'+1}$ is a matter of taste. Being independent of M, M' and q, this prefactor can equally well be included in $\langle J'||T_k||J\rangle$ (as some authors do).

integral and $(-1)^{J-J'} = (-1)^{-J+J'}$. In preparation for the application of sum rules it is useful to rewrite the Wigner-Eckart theorem in the form

$$\langle J'M'|T_{k,q}|JM\rangle = (-1)^{J-M}\frac{1}{\sqrt{2k+1}}\langle J'||T_k||J\rangle (J'M';J,-M|kq\rangle. \tag{K.25}$$

K.2.1 Reduction of matrix elements

Properties of the reduced matrix elements can be derived with the aid of *sum rules*. As will be shown, these rules are most conveniently applied in the Dirac notation starting from Eq. (K.25). This expression can be inverted by multiplying both sides by $(-1)^{J-M}\langle k'q'|J',M;J,-M)$ and summing over M and M'. For the evaluation we return to the $3j$ notation

$$\langle J'||T_k||J\rangle = (2k+1)\sum_{M,M'}(-1)^{J'-M'}\begin{pmatrix} J' & k & J \\ -M' & q & M \end{pmatrix}\langle J'M'|T_{k,q}|JM\rangle. \tag{K.26}$$

Another example is to sum both sides of the Wigner-Eckart theorem (K.22) over M and q,

$$\begin{aligned}\sum_{M,q}|\langle J'M'|T_{k,q}|JM\rangle|^2 &= \frac{1}{2J'+1}|\langle J'||T_k||J\rangle|^2\sum_{M,q}\langle J'M'|JM,k,q)(JM,k,q|J'M'\rangle \\ &= \frac{1}{2J'+1}|\langle J'||T_k||J\rangle|^2.\end{aligned}$$

Next we sum over all $2J'+1$ possible values of M' and arrive at

$$\sum_{M',M,q}|\langle J'M'|T_{k,q}|JM\rangle|^2 = |\langle J'||T_k||J\rangle|^2, \tag{K.27}$$

which is manifestly independent of M, M' and q.

K.2.2 Proof of Wigner-Eckart theorem

The proof proceeds in four steps

1. First we show that the matrix elements satisfy the projection rule (J.5) of the $3j$ symbols. Using the commutation relation (K.3a) we have

   $$q\hbar\langle J'M'|T_{k,q}|JM\rangle = \langle J'M'|[J_z,T_{k,q}]|JM\rangle.$$

   Expanding the commutator and using the hermiticity of J_z this becomes

   $$q\langle J'M'|T_{k,q}|JM\rangle = (M'-M)\,\langle J'M'|T_{k,q}|JM\rangle. \tag{K.28}$$

   Thus we obtained the projection rule (J.5): $\langle J'M'|T_{k,q}|JM\rangle = 0$ unless $q = M'-M$, which can be expressed as

   $$\langle J'M'|T_{k,q}|JM\rangle = \lambda\langle J'M'|J_q|JM\rangle \tag{K.29}$$

   because also $\langle J'M'|J_q|JM\rangle$ is zero unless $q = M'-M$. Our conjecture is that the proportionality constant λ corresponds to the reduced matrix element that we are looking for,

   $$\lambda = (2J'+1)^{-1/2}\,\langle J'||T_k||J\rangle. \tag{K.30}$$

   However, for the time being it remains to be shown that in Eq. (K.29) the *same* value for λ can be used for any combination of M, M' and q; in other words, we have to show that the value of λ is *independent* of M, M' and q. For the special case of vector operators ($k=1$) we recognize in Eq. (K.29) the structure of the *vector projection rule* used in the addition of angular momenta; *e.g.*, for $\mathbf{J} = \mathbf{L}+\mathbf{S}$ we find for $T_{1,q} = L_q$

   $$\langle J'M'|L_q|JM\rangle = \lambda\langle J'M'|J_q|JM\rangle. \tag{K.31}$$

2. To prove the Wigner-Eckart theorem we have to show that

$$\langle J'M'|T_{k,q}|JM\rangle = \lambda\langle JM,k,q|J'M'\rangle, \tag{K.32}$$

where the differences between different combinations of M, M' and q are contained in the Clebsch-Gordan coefficient $\langle JM,k,q|J'M'\rangle$ and the prefactor λ is *independent* of these values. This suggests the strategy to search for two equivalent recursion relations for *given* values of J, J' and k, one for the matrix elements $\langle J'M'|T_{k,q}|JM\rangle$ and the other for the corresponding Clebsch-Gordan coefficients $\langle JM,k,q|J'M'\rangle$, both relating terms with different combinations of M, M' and q. For the matrix elements such a relation follows from the commutation relation (K.3b),

$$\sqrt{k\left(k+1\right)-q\left(q\pm1\right)}\hbar\langle J'M'|T_{k,q\pm1}|JM\rangle = \langle J'M'|[J_\pm,T_{k,q}]|JM\rangle \tag{K.33}$$

Expanding the commutator and using the property that J_+ and J_- are hermitian conjugates we find

$$\begin{aligned}\sqrt{k\left(k+1\right)-q\left(q\pm1\right)}\langle J'M'|T_{k,q\pm1}|JM\rangle &= \\ = \sqrt{J'\left(J'+1\right)-M'\left(M'\mp1\right)}&\langle J'\left(M'\mp1\right)|T_{k,q}|JM\rangle- \\ -\sqrt{J\left(J+1\right)-M\left(M\pm1\right)}&\langle J'M'|T_{k,q}|J\left(M\pm1\right)\rangle.\end{aligned} \tag{K.34}$$

3. To find the equivalent recursion relation for the Clebsch-Gordan coefficients we use the addition of two angular momenta $\mathbf{J}'=\mathbf{J}+\mathbf{k}$ and apply Clebsch-Gordan decomposition of the *coupled* states $|J'M'\rangle$ onto the *uncoupled* basis $\{|JM,kq\rangle\}$. The properties of the coupling vector, $\mathbf{k}$, is determined by the rank, k, of the tensor $T_{k,q}$. If $T_{k,q}$ represents a vector operator $\mathbf{J}$ and $\mathbf{J}'$ can differ by at most one unit of angular momentum ($k=1$ and $-1\le q\le1$); for second-rank tensors by at most two units of angular momentum ($k=2$ and $-2\le q\le2$), etc.. To obtain the recursion relation we use the operator identity

$$\lambda J'_\pm = \lambda J_\pm + \lambda k_\pm, \tag{K.35}$$

where λ can be any constant. First, we operate the l.h.s. onto the state $|J'M'\rangle$ and find

$$\lambda J'_\mp|J'M'\rangle = \lambda\sqrt{J'\left(J'+1\right)-M'\left(M'\mp1\right)}\hbar|J'\left(M'\mp1\right)\rangle \tag{K.36}$$

and subsequently, after decomposition of $|J'\left(M'\mp1\right)\rangle$ with respect to the basis $\{|JM,kq\rangle\}$, this becomes

$$\lambda J'_\mp|J'M'\rangle = \lambda\sqrt{J'\left(J'+1\right)-M'\left(M'\mp1\right)}\hbar\sum_{Mq}|JM,kq\rangle\langle JM,kq|J'\left(M'\mp1\right)\rangle. \tag{K.37}$$

Note that at this point we already obtained an expression that carries the same prefactor and quantum numbers as the first term on the r.h.s. of Eq. (K.34). Second, we start with the decomposition

$$|J'M'\rangle = \sum_{Mq}|JM,kq\rangle\langle JM,kq|J'M'\rangle \tag{K.38}$$

and subsequently operate the r.h.s. of the identity (K.35) onto the states $|JM,kq\rangle$,

$$\begin{aligned}\lambda J'_\mp|J'M'\rangle = &\sum_{Mq}\lambda\sqrt{J\left(J+1\right)-M\left(M\mp1\right)}\hbar|J\left(M\mp1\right),kq\rangle\langle JM,kq|J'M'\rangle \\ &+\sum_{Mq}\lambda\sqrt{k\left(k+1\right)-q\left(q\mp1\right)}\hbar|JM,k\left(q\mp1\right)\rangle\langle JM,kq|J'M'\rangle.\end{aligned} \tag{K.39}$$

Note that we can bring λ under the summation as long as it is independent of M, M' and q. Comparing this expression with the recursion relation (K.34) we note that the Clebsch-Gordan coefficients have to be shifted to serve our purpose. This is easily realized by relabeling of quantum numbers ($M \to M'' \pm 1$ and $q \to q'' \pm 1$) and summing over the new dummy indices (M'' or q'') which is allowed because the projection rule (J.5) assures that the summation total is not affected,

$$\begin{aligned}\lambda J'_{\mp}|J'M'\rangle = &\sum_{M''q} \lambda\sqrt{J\,(J+1) - M''\,(M''\pm 1)}\hbar|JM'', kq\rangle\langle J(M''\pm 1), kq|J'M'\rangle \\ &+ \sum_{Mq''} \lambda\sqrt{k\,(k+1) - q''\,(q''\pm 1)}\hbar|JM, kq''\rangle\langle JM, k(q''\pm 1)|J'M'\rangle. \qquad \text{(K.40)}\end{aligned}$$

After again renaming the dummy indices, $M'' \to M$ and $q'' \to q$, we equate the expansions (K.37) and (K.40) term by term and obtain the relation

$$\begin{aligned}&\lambda\sqrt{k\,(k+1) - q\,(q\pm 1)}\langle JM, k\,(q\pm 1)\,|J'M'\rangle = \\ &\quad = \lambda\sqrt{J'\,(J'+1) - M'\,(M'\mp 1)}\langle JM, kq|J'\,(M'\mp 1)\rangle - \\ &\quad\quad - \lambda\sqrt{J\,(J+1) - M\,(M\pm 1)}\langle J\,(M\pm 1)\,, kq|J'M'\rangle, \qquad \text{(K.41)}\end{aligned}$$

where we know that λ can depend on J, J' and k but certainly does not depend on M, M' and q; *i.e.*, this recursion relation holds for any value of of M, M' and q. Note that all square root prefactors coincide with those of Eq. (K.34). So, with Eq. (K.41), we succeeded in our goal to relate the matrix elements of Eq. (K.34) to Clebsch-Gordan coefficients multiplied by a coefficient λ which does not depend on the combination of M', M and q; comparing Eqs. (K.34) and (K.41) we identify

$$\left.\begin{aligned}\langle J'M'|T_{k,q\pm 1}|JM\rangle &= \lambda\langle JM, k\,(q\pm 1)\,|J'M'\rangle \\ \langle J'\,(M'\mp 1)\,|T_{k,q}|JM\rangle &= \lambda\langle JM, kq|J'\,(M'\mp 1)\rangle \\ \langle J'M'|T_{k,q}|J\,(M\pm 1)\rangle &= \lambda\langle J\,(M\pm 1)\,, kq|J'M'\rangle\end{aligned}\right\} \qquad \text{(K.42)}$$

Using the appropriate change of the dummy indices ($q \pm 1 \to q$, $M' \mp 1 \to M'$, $M \pm 1 \to M$) these three equations all reduce to a single relation,

$$\langle J'M'|T_{k,q}|JM\rangle = \lambda\langle JM, kq|J'M'\rangle. \qquad \text{(K.43)}$$

4. As this relation holds with the same value of λ for any combination of M, M' and q, we have proved the existence of a prefactor with the properties of the reduced matrix element introduced in Eq. (K.22) and we may adopt the notation

$$\lambda = (2J'+1)^{-1/2}\,\langle J'||T_k||J\rangle, \qquad \text{(K.44)}$$

which completes the proof.

K.3 Examples

K.3.1 Reduced matrix elements and hermitian conjugation of spherical tensor operators

Consider the following two expressions based on the Wigner-Eckart theorem:

$$\langle J'M'|T^{\dagger}_{k,q}|JM\rangle = \langle JM|T_{k,q}|J'M'\rangle^{*} = (-1)^{J'-k+M}\langle J||T_k||J'\rangle^{*}\begin{pmatrix} J' & k & J \\ M' & q & -M\end{pmatrix} \qquad \text{(K.45a)}$$

$$\langle J'M'|T_{k,-q}|JM\rangle = (-1)^{J-k+M'}\langle J'||T_k||J\rangle\begin{pmatrix} J & k & J' \\ M & -q & -M'\end{pmatrix}. \qquad \text{(K.45b)}$$

Eliminating the $3j$ symbols and using the condition $q = M - M'$ these expressions combine to

$$\langle J'M'|T_{k,q}^{\dagger}|JM\rangle = \frac{(-1)^{J-J'+q}\langle J||T_k||J'\rangle^*}{\langle J'||T_k||J\rangle}\langle J'M'|T_{k,-q}|JM\rangle. \tag{K.46}$$

Since $\langle J'||T_k||J\rangle$ is independent of M, M' and q we can determine the relation between $\langle J'||T_k||J\rangle$ and $\langle J||T_k||J'\rangle^*$ by choosing the most convenient matrix element for this purpose. For *integer rank* we can choose $q = 0$ and obtain

$$\langle J'M'|T_{k,0}^{\dagger}|JM\rangle = \frac{(-1)^{J-J'}\langle J||T_k||J'\rangle^*}{\langle J'||T_k||J\rangle}\langle J'M'|T_{k,0}|JM\rangle. \tag{K.47}$$

Since, for *integer rank*, $T_{k,0}$ is invariant under rotation, we have $T_{k,0}^{\dagger} = T_{k,0}$ and the above equation reduces to

$$\langle J'||T_k||J\rangle = (-1)^{J-J'}\langle J||T_k||J'\rangle^*. \tag{K.48}$$

K.3.2 Reduced matrix elements for angular momentum operators

To determine the reduced matrix element $\langle J'||J||J\rangle$ the Wigner-Eckart theorem is written in the form

$$\langle J'||J||J\rangle = (-1)^{J'-M'}\langle J'M'|J_q|JM\rangle \begin{pmatrix} J' & 1 & J \\ -M' & q & M \end{pmatrix}^{-1}. \tag{K.49}$$

Since $\langle J'||T_k||J\rangle$ is independent of M, M' and q we can use the most convenient matrix element to determine its value. We demonstrate this by choosing $q = 0$ and $M = M' = J$ and obtain with the aid of Eq. (J.18a)

$$\langle J'||J||J\rangle = \langle J'J'|J_0|JJ\rangle \begin{pmatrix} J' & 1 & J \\ -J' & 0 & J \end{pmatrix}^{-1} = \sqrt{J(J+1)(2J+1)}\,\delta_{J,J'}. \tag{K.50}$$

Hence, for arbitrary q, M and M' the angular momentum matrix elements can be written in the form

$$\langle J'M'|J_q|JM\rangle = (-1)^{J+M'-1}\sqrt{J(J+1)(2J+1)} \begin{pmatrix} J & 1 & J \\ M & q & -M' \end{pmatrix} \delta_{J,J'}. \tag{K.51}$$

Using Eqs. (J.18) it is readily verified that this one equation is equivalent to the set of Eqs. (3.22b) and (3.24b).

K.3.3 Reduced matrix elements for the spherical harmonics

As a second example we discuss the determination of the reduced matrix elements of tensor operators of the spherical harmonic type. This is done by comparing the expression obtained by applying the Wigner-Eckart theorem with the result of the Gaunt integral (L.59).

$$\langle l'm'|Y_k^q(\hat{\mathbf{r}})|lm\rangle = \begin{cases} (-1)^{m'+l'}\langle l'||Y_k(\hat{\mathbf{r}})||l\rangle \begin{pmatrix} l' & k & l \\ -m' & q & m \end{pmatrix} \\ (-1)^{m'}\sqrt{\dfrac{(2l'+1)(2k+1)(2l+1)}{4\pi}} \begin{pmatrix} l' & k & l \\ 0 & 0 & 0 \end{pmatrix} \begin{pmatrix} l' & k & l \\ -m' & q & m \end{pmatrix}. \end{cases} \tag{K.52}$$

This comparison yields

$$\langle l'||Y_k(\hat{\mathbf{r}})||l\rangle = (-1)^{-l'}\sqrt{\frac{(2l'+1)(2k+1)(2l+1)}{4\pi}} \begin{pmatrix} l' & k & l \\ 0 & 0 & 0 \end{pmatrix}, \tag{K.53}$$

which is only nonzero for even values of $k+l+l'$.

Some special cases are:

- $k=0$: Substituting the $3j$ symbol (J.23) we find
$$\langle l'||\sqrt{4\pi}Y_0(\hat{\mathbf{r}})||l\rangle = \sqrt{2l+1}\,\delta_{l,l'}. \tag{K.54}$$
- $k=1$: Substituting the $3j$ symbol (J.24) we find
$$\langle l'||\sqrt{4\pi/3}Y_1(\hat{\mathbf{r}})||l\rangle = (-1)^{-l'+\max(l,l')}\sqrt{\max(l,l')}\,\delta_{l',l\pm1} = \pm\sqrt{\max(l,l')}\,\delta_{l',l\pm1}. \tag{K.55}$$
- $k=2$: Substituting the $3j$ symbol (J.25) we find
$$\langle l'||\sqrt{4\pi/5}Y_2(\hat{\mathbf{r}})||l\rangle = \begin{cases} -\sqrt{\dfrac{l\,(l+1)\,(2l+1)}{(2l+3)(2l-1)}} & l'=l \\ +\sqrt{\max(l,l')\left(\dfrac{3}{4}\dfrac{l+l'}{l+l'+1}\right)} & l'=l\pm2. \end{cases} \tag{K.56}$$

K.3.4 Reduction of matrix elements of vector operators

As a first example we consider the reduction of the matrix elements $\langle lsJ'M'|\,L_q\,|lsJM\rangle$ of the orbital angular momentum operator $\mathbf{L}$ expressed in the basis $\{|JM\rangle\}$ of the standard representation $\{J^2, J_z\}$ of the total angular momentum operator $\mathbf{J}=\mathbf{L}+\mathbf{S}$. Our aim is to show that
$$\langle lsJ\,(M\pm q)|\,L_q\,|lsJM\rangle = \langle lsJ||L||lsJ\rangle\,\langle lsJ\,(M\pm q)|\,J_q\,|lsJM\rangle \qquad \text{for } q=0,\pm1, \tag{K.57}$$
where L_q and J_q are the standard components of the vector operators $\mathbf{L}$ and $\mathbf{J}$, respectively, and $\langle lsJ||L||lsJ\rangle$ is a proportionality constant independent of M and q.

We start by applying the Wigner-Eckart theorem (K.24) to the standard components L_q of the rank 1 tensor $\mathbf{L}$,
$$\langle lsJM'|\,L_q\,|lsJM\rangle = (-)^{J'-M'}\langle lsJ||L||lsJ\rangle \begin{pmatrix} J & 1 & J \\ -M' & q & M \end{pmatrix} \qquad \text{with } q=0,\pm1. \tag{K.58}$$

These matrix elements are only non-zero for $M'=M+q$. We evaluate subsequently the cases $q=0,\pm1$ using the expressions (J.18a) and (J.18b) for $3j$ symbols,
$$\begin{aligned}\langle lsJM|\,L_z\,|lsJM\rangle &= (-)^{J-M}\langle lsJ||L||lsJ\rangle \begin{pmatrix} J & 1 & J \\ -M & 0 & M \end{pmatrix} \\ &= \frac{\langle lsJ||L||lsJ\rangle}{\sqrt{J\,(J+1)\,(2J+1)}}\,M\,\hbar \end{aligned} \tag{K.59a}$$

$$\begin{aligned}\langle lsJ\,(M\pm1)|\,L_\pm\,|lsJM\rangle &= (-)^{J-M\mp1}\langle lsJ||L||lsJ\rangle\sqrt{2}\,\hbar \begin{pmatrix} J & 1 & J \\ -(M\pm1) & \pm1 & M \end{pmatrix} \\ &= \frac{\langle lsJ||L||lsJ\rangle}{\sqrt{J\,(J+1)\,(2J+1)}}\sqrt{J(J+1)-M(M\pm1)}\,\hbar. \end{aligned} \tag{K.59b}$$

Absorbing the joint prefactor $\sqrt{J\,(J+1)\,(2J+1)}$ into the reduced matrix element (it is independent of M, M' and q) and using the definitions of the J_z and $J_\pm$ operators we can rewrite Eqs. (K.59a) and (K.59b) in the form
$$\langle lsJM|\,L_z\,|lsJM\rangle = \langle lsJ||L||lsJ\rangle\,\langle lsJM|\,J_z\,|lsJM\rangle \tag{K.60a}$$
$$\langle lsJ\,(M\pm1)|\,L_\pm\,|lsJM\rangle = \langle lsJ||L||lsJ\rangle\,\langle lsJ\,(M\pm1)|\,J_\pm\,|lsJM\rangle\,. \tag{K.60b}$$

Here we recognize the *vector projection rule* used for describing the atomic fine structure in the low-field limit. Using the definitions $J_0 = (J_z/\hbar)$ and $J_{\pm 1} = \sqrt{1/2}\,(J_\pm/\hbar)$ these equations reduce to Eq. (K.57).

K.3.5 Calculation of reduced matrix elements in coupled bases

The Wigner-Eckart theorem allows the reduction of matrix elements involving coupled angular momenta. In this section we illustrate this for two angular momentum operators, $\boldsymbol{j_1}$ and $\boldsymbol{j_2}$, acting in the two (independent) subspaces of the representations $\{\boldsymbol{j}_1^2, j_{1z}\}$ and $\{\boldsymbol{j}_2^2, j_{2z}\}$, respectively, and together spanning the angular momentum space $\{\mathbf{J}^2, J_z\}$, where $\mathbf{J} = \boldsymbol{j}_1 + \boldsymbol{j}_2$ is the coupled angular momentum. Let us consider matrix elements of the type $\langle j_1' j_2 J' M' | T_{1:k,q} | j_1 j_2 J M\rangle$, where $T_{1:k,q}$ is a spherical tensor operator acting in *one* of the subspaces, the subspace defined by the basis $\{|j_1, m_1\}$, but the matrix element is expressed in the basis $\{|JM\rangle\}$ of the standard representation $\{\mathbf{J}^2, J_z\}$. Applying the Wigner-Eckart theorem we obtain

$$\langle j_1' j_2 J' M' | T_{1:k,q} | j_1 j_2 J M\rangle = (-1)^{J'-M'} \langle j_1' j_2 J' || \mathrm{T}_1^{(k)} || j_1 j_2 J\rangle \begin{pmatrix} J' & k & J \\ -M' & q & M \end{pmatrix}. \tag{K.61}$$

In view of the properties of the $3j$ symbols this matrix element is nonzero *only* for $q = M' - M$. In other words, for given values of M and M' only a *single* component of the tensor $\mathrm{T}_1^{(k)}$ is nonzero. Furthermore, as $\mathrm{T}_1^{(k)}$ operates within the subspace $\{|j_1, m_1\}$ it leaves the quantum numbers j_2 and m_2 unaffected. Hence, only the matrix elements diagonal in j_2 and m_2 are nonzero and it is our task is to determine reduced matrix elements of the type $\langle j_1' j_2 J' || \mathrm{T}_1^{(k)} || j_1 j_2 J\rangle$. In Problem K.2 we show that these are given by the expression for *repeated reduction*

$$\langle j_1' j_2 J' || \mathrm{T}_1^{(k)} || j_1 j_2 J\rangle = (-1)^{J+j_1'+j_2+j_1} \langle j_1' || \mathrm{T}_1^{(k)} || j_1\rangle \sqrt{(2J+1)(2J'+1)} \begin{Bmatrix} j_1' & J' & j_2 \\ J & j_1 & k \end{Bmatrix}, \tag{K.62}$$

where $\langle j_1' || \mathrm{T}_1^{(k)} || j_1\rangle$ is the reduced matrix element of $\mathrm{T}_1^{(k)}$ within the subspace $\{\boldsymbol{j}_1^2, j_{1z}\}$ as given by (K.50). Note that the reduced matrix element is independent of magnetic quantum numbers.

Analogously, we can reduce the matrix elements of scalar invariants of the type

$$\mathrm{T}_1^{(k)} \cdot \mathrm{T}_2^{(k)} = \sum_{m=-k}^{k} (-1)^m T_{1:k,m} T_{2:k,-m}, \tag{K.63}$$

where $\mathrm{T}_1^{(k)}$ and $\mathrm{T}_2^{(k)}$ operate in the two (independent) subspaces of the representations $\{\boldsymbol{j}_1^2, j_{1z}\}$ and $\{\boldsymbol{j}_2^2, j_{2z}\}$, respectively. In this case the repeated reduction (K.62) leads to the following expression - see Problem K.3

$$\langle j_1' j_2' J' M' | \mathrm{T}_1^{(k)} \cdot \mathrm{T}_2^{(k)} | j_1 j_2 J M\rangle = (-1)^{j_1+j_2+j_{1'}} \langle j_1' || \mathrm{T}_1^{(k)} || j_1\rangle \langle j_2' || \mathrm{T}_2^{(k)} || j_2\rangle \begin{Bmatrix} j_1' & j_2' & J \\ j_2 & j_1 & k \end{Bmatrix} \delta_{J,J'} \delta_{M,M'}. \tag{K.64}$$

Example K.3. As a first example we consider the coupling of the orbital angular momentum $\mathbf{L}$ with the spin $\mathbf{S}$, to form the total electronic angular momentum $\mathbf{J} = \mathbf{L} + \mathbf{S}$. Let us consider matrix elements of the type $\langle l' s j' M' |\, T_{k,q}\, | lsjM\rangle$, where $T_{k,q}$ is a spherical tensor operator operating in the subspace $\{\mathbf{L}^2, L_z\}$ of the orbital angular momentum but the matrix element is expressed in the basis $\{|jM\rangle\}$ of the total electronic angular momentum standard representation $\{\mathbf{J}^2, J_z\}$. With $\langle l' || T_k || l\rangle$ given by (K.50), the expression for the repeated reduction is

$$\langle l' s j' || T_k || l s j\rangle = (-1)^{j+k+l'+s} \langle l' || T_k || l\rangle \sqrt{(2j+1)(2j'+1)} \begin{Bmatrix} l' & j' & s \\ j & l & k \end{Bmatrix}. \tag{K.65}$$

Example K.4. As a second example we consider the coupling of the total electronic angular momentum $\mathbf{J}$ with the nuclear spin $\mathbf{I}$, to form the total angular momentum $\mathbf{F}=\mathbf{J}+\mathbf{I}$. Let us consider matrix elements of the type $\langle j'IF'M'|\,T_{k,q}\,|jIFM\rangle$, where $T_{k,q}$ is a spherical operator operating in the subspace $\{\mathbf{J}^2,J_z\}$ of the orbital angular momentum but the matrix element is expressed in the basis $\{|FM\rangle\}$ of the total electronic angular momentum standard representation $\{\mathbf{F}^2,F_z\}$. With $\langle j'||T_k||j\rangle$ given by (K.50), the expression for the repeated reduction is

$$\langle j'IF||T_k||jIF\rangle=(-1)^{F+k+j'+I}\langle j'||T_k||j\rangle\sqrt{(2F+1)\,(2F'+1)}\begin{Bmatrix} j' & F' & I\\ F & j & k\end{Bmatrix}. \tag{K.66}$$

Example K.5. Actually, in the previous example the total electronic angular momentum is itself composed of two angular momenta, $\mathbf{J}=\mathbf{L}+\mathbf{S}$. If the spherical tensor operator T_k only acts in one of the subspaces, say the subspace of $\{\mathbf{L}^2,L_z\}$ we can repeat the reduction by substituting Eq. (K.65) into Eq. (K.66). In this way we reduce the matrix element from the standard representation $\{\mathbf{F}^2,F_z\}$ to the standard representation $\{\mathbf{L}^2,L_z\}$. Using the relation $(-1)^{2k}=1$ we find

$$\begin{aligned}\langle j'IF||T_k||jIF\rangle=(-1)^{F+j'+j+l'+s+I}\langle l'||T_k||l\rangle&\\ \times\sqrt{(2j+1)\,(2j'+1)\,(2F+1)\,(2F'+1)}&\begin{Bmatrix} l' & j' & s\\ j & l & k\end{Bmatrix}\begin{Bmatrix} j' & F' & I\\ F & j & k\end{Bmatrix}.\end{aligned} \tag{K.67}$$

Problem K.2. Derive Eq. (K.62).

Solution. We start by decomposing Eq. (K.61) with respect to the uncoupled basis $\{|jmsm_s)\}$,

$$\langle j'sJ'M'|\,T_{k,q}\,|jsJM\rangle=\sum_{m,m',m_s}\langle J'M'|j'm'sm_s)\langle j'm'|T_{k,q}|jm\rangle(jmsm_s\,|JM\rangle\,. \tag{K.68}$$

Expressing the Clebsch-Gordan coefficients in terms of Wigner $3j$ symbols using Eq. (J.1) we have

$$(jmsm_s|JM\rangle=(-1)^{j-s+M}\sqrt{2J+1}\begin{pmatrix} j & s & J\\ m & m_s & -M\end{pmatrix} \tag{K.69a}$$

$$(j'm'sm_s|J'M'\rangle=(-1)^{j'-s+M'}\sqrt{2J'+1}\begin{pmatrix} j' & s & J'\\ m' & m_s & -M'\end{pmatrix}. \tag{K.69b}$$

To evaluate $\langle j'm'|T_{k,q}|jm\rangle$ we use the Wigner-Eckart theorem,

$$\langle j'm'|T_{k,q}|jm\rangle=(-1)^{j'-m'}\langle j'||T_k||j\rangle\begin{pmatrix} j' & k & j\\ -m' & q & m\end{pmatrix}. \tag{K.70}$$

If the reduced matrix element $\langle j'||T_k||j\rangle$ cannot be reduced any further (i.e., $\boldsymbol{j}$ is not a composite angular momentum itself) it can be determined by direct evaluation of the l.h.s. of Eq. (K.70), as was demonstrated for the $\langle j'||Y_k(\hat{\mathbf{r}})||j\rangle$ in Section K.3.3. To evaluate Eq. (K.68) we substitute Eqs. (K.69a), (K.69b) and (K.70). Collecting the phase factors we obtain

$$(-1)^{2j'+j-2s+M'+M-m'}. \tag{K.71}$$

Using the properties of the $3j$ symbols we know that $M=m_s+m$ and $M'=m_s+m'$; hence, $M'+M-m'=2m_s+m=-M'+4m_s+m-m_s+m'$. Furthermore, since $4m_s$ is even we have $(-1)^{4m_s}=1$. Likewise we have $(-1)^{-2s}=(-1)^{2s}$ because $2s$ is an integer. Hence, Eq. (K.68) can be written in the form

$$\begin{aligned}\langle j'sJ'M'|\,T_{k,q}\,|jsJM\rangle=\langle j'||T_k||j\rangle\sqrt{(2J+1)\,(2J'+1)}\sum_{m,m',m_s}(-1)^{2j'+j-2s-M'+m-m_s+m'}&\\ \times\begin{pmatrix} j & s & J\\ m & m_s & -M\end{pmatrix}\begin{pmatrix} j' & s & J'\\ m' & m_s & -M'\end{pmatrix}\begin{pmatrix} j' & k & j\\ -m' & q & m\end{pmatrix}&.\end{aligned} \tag{K.72}$$

Next we bring the triple product of the $3j$ symbols in the order of triple-product summation formula (J.36). For this we first reorder the second and third $3j$ symbols,

$$\langle j'sJ'M'|\, T_{k,q}\, |jsJM\rangle = \langle j'||T_k||j\rangle\sqrt{(2J+1)\,(2J'+1)}\sum_{m,m',m_s}(-1)^{2j'+j+2s-M'+m+m_s+m'} \times\begin{pmatrix} j & s & J \\ m & -m_s & -M \end{pmatrix}\begin{pmatrix} s & j' & J' \\ m_s & -m' & M' \end{pmatrix}\begin{pmatrix} j' & j & k \\ m' & -m & -q \end{pmatrix}. \quad (K.73)$$

Note that we have replaced m_s by $-m_s$, which is allowed because we sum over all values of m_s. At this point we can apply the $3j$ triple-product summation formula and obtain (after using the sign rule for $3j$ symbols)

$$\langle j'sJ'M'|\, T_{k,q}\, |jsJM\rangle = (-1)^{J'+J+k}(-1)^{j'+s-M'}\langle j'||T_k||j\rangle \times\sqrt{(2J+1)\,(2J'+1)}\begin{Bmatrix} J' & k & J \\ j & s & j' \end{Bmatrix}\begin{pmatrix} J' & k & J \\ -M' & q & M \end{pmatrix}. \quad (K.74)$$

Comparing Eq. (K.74) with Eq. (K.61) we find

$$\langle j'sJ'||T_k||jsJ\rangle = (-1)^{J+k+j'+s}\langle j'||T_k||j\rangle\sqrt{(2J+1)\,(2J'+1)}\begin{Bmatrix} J' & k & J \\ j & s & j' \end{Bmatrix}. \quad (K.75)$$

Rearranging the $6j$ symbols using the relations (J.29) and (J.30) we arrive at Eq. (K.62). ☐

Problem K.3. Derive Eq. (K.64).

Solution. Starting from the scalar invariant $\mathrm{T}_1^{(k)}\cdot\mathrm{T}_2^{(k)}=\sum_{m=-k}^{k}(-1)^m T_{1:k,m}T_{2:k,-m}$, we separate the matrix element into parts for $\mathrm{T}_1^{(k)}$ and $\mathrm{T}_2^{(k)}$, operating in the two (independent) subspaces of the representations $\{\boldsymbol{j}_1^2, j_{1z}\}$ and $\{\boldsymbol{j}_2^2, j_{2z}\}$, respectively,

$$\begin{aligned}\langle j_1'j_2'J'M'|\mathrm{T}_1^{(k)}\cdot\mathrm{T}_2^{(k)}|j_1j_2JM\rangle &= \sum_{q=-k}^{k}(-1)^m\langle j_1'j_2'J'M'|T_{1:k,q}T_{2:k,-q}|j_1j_2JM\rangle \\ &= \sum_{j_1''j_2''}\sum_{J'',M''}\sum_{q=-k}^{k}(-1)^q\langle j_1'j_2'J'M'|T_{1:k,q}|j_1''j_2''J''M''\rangle\langle j_1''j_2''J''M''|T_{2:k,-q}|j_1j_2JM\rangle.\end{aligned}$$

Applying the Wigner-Eckart theorem to each of these parts we obtain

$$\langle j_1'j_2'J'M'|\mathrm{T}_1^{(k)}\cdot\mathrm{T}_2^{(k)}|j_1j_2JM\rangle = \sum_{J'',M''}\sum_{q=-k}^{k}(-1)^{q+J'-M'+J''-M''} \langle j_1'j_2'J'||\mathrm{T}_1^{(k)}||j_1j_2'J''\rangle\langle j_1j_2'J''||\mathrm{T}_2^{(k)}||j_1j_2J\rangle\begin{pmatrix} J' & k & J'' \\ -M' & q & M'' \end{pmatrix}\begin{pmatrix} J'' & k & J \\ -M'' & -q & M \end{pmatrix}.$$

In view of the $3j$ projection rule we have $q=M'-M''$ and $(-1)^{q+J'-M'+J''-M''}=(-1)^{J'+J''-2M''}$. Adding and subtracting J'' in the exponent and noting that $2(J''-M'')$ is even, the matrix element becomes after some rearrangement of the left $3j$ symbol

$$\langle j_1'j_2'J'M'|\mathrm{T}_1^{(k)}\cdot\mathrm{T}_2^{(k)}|j_1j_2JM\rangle = \sum_{J''}(-1)^{J'-J''} \langle j_1'j_2'J'||\mathrm{T}_1^{(k)}||j_1j_2'J''\rangle\langle j_1j_2'J''||\mathrm{T}_2^{(k)}||j_1j_2J\rangle\sum_{M''=-J''}^{J''}\sum_{q=-k}^{k}\begin{pmatrix} J'' & k & J' \\ -M'' & -q & M' \end{pmatrix}\begin{pmatrix} J'' & k & J \\ -M'' & -q & M \end{pmatrix}.$$

In this form we can apply the orthogonality relation (J.6) and simplify the expression,

$$\langle j_1' j_2' J' M' | \mathrm{T}_1^{(k)} \cdot \mathrm{T}_2^{(k)} | j_1 j_2 J M \rangle = \sum_{J''} (-1)^{J'-J''} \langle j_1' j_2' J' || \mathrm{T}_1^{(k)} || j_1 j_2' J'' \rangle \langle j_1 j_2' J'' || \mathrm{T}_2^{(k)} || j_1 j_2 J \rangle \, \frac{\delta_{J,J'} \delta_{M,M'}}{2J+1}.$$

Using the repeated reduction relation (K.62) twice the expression for the matrix element becomes

$$\langle j_1' j_2' J' M' | \mathrm{T}_1^{(k)} \cdot \mathrm{T}_2^{(k)} | j_1 j_2 J M \rangle = \langle j_1' || \mathrm{T}_1^{(k)} || j_1 \rangle \langle j_2' || \mathrm{T}_2^{(k)} || j_2 \rangle \sum_{J''} (-1)^{J'+J+2j_1+j_2+2j_2'+j_1'} \left(2J''+1\right) \begin{Bmatrix} j_1' & J' & j_2 \\ J'' & j_1 & k \end{Bmatrix} \begin{Bmatrix} j_2 & J'' & j_1 \\ J & j_2' & k \end{Bmatrix} \delta_{J,J'} \delta_{M,M'}.$$

Rearranging the $6j$ symbols for applying the sum rule (J.34) and arrive at the desired expression.

$$\langle j_1' j_2' J' M' | \mathrm{T}_1^{(k)} \cdot \mathrm{T}_2^{(k)} | j_1 j_2 J M \rangle = \langle j_1' || \mathrm{T}_1^{(k)} || j_1 \rangle \langle j_2' || \mathrm{T}_2^{(k)} || j_2 \rangle (-1)^{J'+J+2j_1+j_2+2j_2'+j_1'} \sum_{J''} \left(2J''+1\right) \begin{Bmatrix} J & j_2 & j_1' \\ j_1 & k & J'' \end{Bmatrix} \begin{Bmatrix} j_2 & j_1 & J'' \\ J & k & j_2' \end{Bmatrix} \delta_{J,J'} \delta_{M,M'}. \quad \square$$

L

Properties of functions, series and integrals

L.1 Finite sums of powers

The best known example is the *arithmetic series*:

$$\sum_{k=1}^{n} a_k = \tfrac{1}{2} n(a_n + a_1), \text{ with } a_{n+1} = a_n + v, \tag{L.1}$$

where v is called the difference between successive terms. In particular, for $a_k = k$ this becomes

$$\sum_{k=1}^{n} k = \tfrac{1}{2} n(n+1). \tag{L.2}$$

Related finite sums are

$$\sum_{k=1}^{n} k^2 = \tfrac{1}{6} n(n+1)(2n+1) \tag{L.3}$$

$$\sum_{k=1}^{n} k^3 = \tfrac{1}{4} n^2(n+1)^2. \tag{L.4}$$

Sums of powers of (generally complex) numbers:

$$\sum_{k=1}^{n} k^n z^k = \left(z\frac{d}{dz} \right)^n \frac{z - z^{n+1}}{1-z}. \tag{L.5}$$

The best known example is the *geometric series*

$$\sum_{k=1}^{n} a_k = a_1 \frac{1-r^n}{1-r}, \text{ with } a_{n+1} = r a_n. \tag{L.6}$$

The factor r is called the ratio of the series; i.e., the ratio of two subsequent terms. Other examples of summations of this type are

$$\sum_{k=1}^{n} k z^k = z \frac{1-(n+1)z^n + n z^{n+1}}{(1-z)^2} \tag{L.7}$$

$$\sum_{k=1}^{n} k^2 z^k = z \frac{1 + z - (n+1)^2 z^n + (2n^2+2n-1) z^{n+1} - n^2 z^{n+2}}{(1-z)^3}. \tag{L.8}$$

L.2 Gamma function

The gamma function is defined for the complex z plane excluding the non-positive integers

$$\int_0^\infty e^{-x}x^{z-1}dx = \Gamma\left(z\right). \tag{L.9}$$

For integer values $z-1=n=0,1,2,\cdots$ the gamma function coincides with the factorial function,

$$\int_0^\infty e^{-x}x^n dx = \Gamma\left(n+1\right) = n! \tag{L.10}$$

Some special values are:

$$\begin{array}{lll}\Gamma\left(-1/2\right) = -2\sqrt{\pi} = -3.545, & \Gamma\left(1/2\right) = \sqrt{\pi} = 1.772, & \Gamma\left(1\right) = 1\\ \Gamma\left(-3/2\right) = \frac{4}{3}\sqrt{\pi} = 2.363, & \Gamma\left(3/2\right) = \frac{1}{2}\sqrt{\pi} = 0.886, & \Gamma\left(2\right) = 1\\ & \Gamma\left(5/2\right) = \frac{3}{4}\sqrt{\pi} = 1.329, & \Gamma\left(3\right) = 2\\ & \Gamma\left(7/2\right) = \frac{15}{8}\sqrt{\pi} = 3.323, & \Gamma\left(4\right) = 6.\end{array} \tag{L.11}$$

Some related integrals are

$$\int_0^\infty e^{-x^2}x^{2n+1}dx = \frac{1}{2}n! \tag{L.12}$$

$$\int_0^\infty e^{-x^2}x^{2n}dx = \frac{(2n-1)!!}{2^{n+1}}\sqrt{\pi}. \tag{L.13}$$

A useful integral relation is

$$\int_0^\infty e^{-\ell x^n}x^m dx = \frac{1}{\ell^{(m+1)/n}}\int_0^\infty e^{-x^n}x^m dx. \tag{L.14}$$

L.3 Polylogarithm

The polylogarithm $\mathrm{Li}_\alpha(z)$ is a special function defined over the unit disk in the complex plane by the series expansion

$$\mathrm{Li}_\alpha(z) = \mathrm{PolyLog}[\alpha, z] \equiv \sum_{\ell=1}^{\infty}\frac{z^\ell}{\ell^\alpha} \qquad (|z|<1), \tag{L.15}$$

where α is an arbitrary complex number. By analytic continuation the polylogarithm can be defined over a larger range of z. For z and α on the *real axis* and for $\alpha>1$ the polylogarithm are given by the Bose-Einstein integrals

$$F_\alpha^{\mathrm{BE}}\left(z\right) = \frac{1}{\Gamma\left(\alpha\right)}\int_0^\infty \frac{x^{\alpha-1}}{z^{-1}e^x-1}dx \qquad (z<1) \tag{L.16}$$

and the Fermi-Dirac integrals

$$F_\alpha^{\mathrm{FD}}\left(z\right) = \frac{1}{\Gamma\left(\alpha\right)}\int_0^\infty \frac{x^{\alpha-1}}{z^{-1}e^x+1}dx \qquad (z\geq -1). \tag{L.17}$$

Recurrence relations:

$$F_\alpha^{\mathrm{BE/FD}}(z) = z\frac{d}{dz}F_{\alpha+1}^{\mathrm{BE/FD}}\left(z\right) \qquad \Leftrightarrow \qquad F_\alpha^{\mathrm{BE/FD}}(e^u) = \frac{d}{du}F_{\alpha+1}^{\mathrm{BE/FD}}(e^u). \tag{L.18}$$

L.4 Bose-Einstein function

The Bose-Einstein (BE) integrals are defined for real z and $\alpha > 1$ as

$$F_{\alpha}^{\mathrm{BE}}(z) = \frac{1}{\Gamma(\alpha)} \int_0^{\infty} \frac{x^{\alpha-1}}{z^{-1}e^{x} - 1} dx \qquad (z < 1). \tag{L.19}$$

The integrals can be expanded in powers of z on the interval $0 < z < 1$,

$$F_{\alpha}^{\mathrm{BE}}(z) = \frac{1}{\Gamma(\alpha)} \sum_{\ell=1}^{\infty} \int_0^{\infty} x^{\alpha-1} z^{\ell} e^{-\ell x} dx = \sum_{\ell=1}^{\infty} \frac{z^{\ell}}{\ell^{\alpha}} = g_{\alpha}(z) = \mathrm{Li}_{\alpha}(z), \tag{L.20}$$

where $\mathrm{Li}_{\alpha}(z)$ is the polylogarithm. For *non-integer* values of α the BE-integrals can also be expanded in the form[1]

$$F_{\alpha}^{\mathrm{BE}}(e^{-u}) = \Gamma(1-\alpha)\, u^{\alpha-1} + \sum_{n=0}^{\infty} \frac{(-1)^n}{n!} \zeta(\alpha - n) u^n, \tag{L.21}$$

where the expansion in powers of $u = -\ln z$ is valid on the interval $0 < u < 2\pi$. For *integer* values $\alpha = m \in \{2, 3, 4, \cdots\}$ the BE-integrals the expansion is

$$F_{m}^{\mathrm{BE}}(e^{-u}) = \frac{(-u)^{m-1}}{(m-1)!} \left(1 + \frac{1}{2} + \frac{1}{3} + \cdots + \frac{1}{m-1} - \ln u\right) u^{m-1} + \sum_{\substack{n=0 \\ \neq m-1}}^{\infty} \frac{\zeta(m-n)}{n!} u^n, \tag{L.22}$$

with convergence for $0 < u \leq 2\pi$.

L.5 Fermi-Dirac function

The Fermi-Dirac (FD) integrals are defined for real z and $\alpha > 1$ as

$$F_{\alpha}^{\mathrm{FD}}(z) = \frac{1}{\Gamma(\alpha)} \int_0^{\infty} \frac{x^{\alpha-1}}{z^{-1}e^{x} + 1} dx \qquad (z \geq -1). \tag{L.23}$$

The integrals can be expanded in powers of z on the interval $0 < z \leq 1$,

$$F_{\alpha}^{\mathrm{FD}}(z) = \frac{-1}{\Gamma(\alpha)} \sum_{\ell=1}^{\infty} \int_0^{\infty} x^{\alpha-1} (-z)^{\ell} e^{-\ell x} dx = -\sum_{\ell=1}^{\infty} \frac{(-z)^{\ell}}{\ell^{\alpha}} = f_{\alpha}(z) = -\mathrm{Li}_{\alpha}(-z), \tag{L.24}$$

where $\mathrm{Li}_{\alpha}(z)$ is the polylogarithm.

L.6 Riemann zeta function

The Riemann zeta function is defined as a Dirichlet series

$$\lim_{z \to 1} g_{\alpha}(z) = \zeta(\alpha) = \sum_{\ell=1}^{\infty} \frac{1}{\ell^{\alpha}}. \tag{L.25}$$

Some special values are:

$$\begin{array}{llll} \zeta(1/2) = -1.460, & \zeta(3/2) = 2.612, & \zeta(5/2) = 1.341, & \zeta(7/2) = 1.127, \\ \zeta(1) \to \infty, & \zeta(2) = \pi^2/6 = 1.645, & \zeta(3) = 1.202, & \zeta(4) = \pi^4/90 = 1.082. \end{array}$$

---

[1] For a derivation see J.E. Robinson, Phys. Rev. 83, 678 (1951).

L.7 Selected integrals and rules

For $\gamma > 0$ and $\varepsilon > 0$

$$\int_0^\varepsilon \sqrt{x}\,(\varepsilon - x)^{\gamma-1}\,dx = \frac{\sqrt{\pi}\Gamma(\gamma)}{2\,\Gamma\,(3/2+\gamma)}\varepsilon^{1/2+\gamma} \tag{L.26}$$

The *Leibniz integral rule* for moving boundaries is given by

$$\frac{d}{dt}\int_{a(t)}^{b(t)} f(x,t)dx = \int_{a(t)}^{b(t)} \frac{\partial}{\partial t} f(x,t)dx + f(x,t)\frac{d}{dt}b(t) - f(x,t)\frac{d}{dt}a(t) \tag{L.27}$$

In particular, for definite integrals with fixed boundaries this integration rule becomes

$$\frac{d}{dt}\int f(x,t)dx = \int \frac{\partial}{\partial t} f(x,t)dx. \tag{L.28}$$

L.8 Commutator algebra

If A, B, C and D are four arbitrary linear operators the following relations hold:

$$[A,B] = -\,[B,A] \tag{L.29a}$$

$$[A,B+C] = [A,B] + [A,C] \tag{L.29b}$$

$$[A,BC] = [A,B]\,C + B\,[A,C] \tag{L.29c}$$

$$[AB,CD] = A[B,C]D + AC[B,D] + [A,C]DB + C[A,D]B \tag{L.29d}$$

$$0 = [A,[B,C]] + [B,[C,A]] + [C,[A,B]]\,. \tag{L.29e}$$

Commutators containing B^n:

$$[A,B^n] = \sum_{s=0}^{n-1} B^s\,[A,B]\,B^{n-s-1} \tag{L.30a}$$

$$[A,B^n] = nB^{n-1}\,[A,B]\ \text{ if } B \text{ commutes with } [A,B]. \tag{L.30b}$$

The exponential operator is defined as:

$$e^A \equiv \sum_{n=0}^{\infty} \frac{A^n}{n!}. \tag{L.31}$$

Baker-Campbell-Hausdorff formula:

$$e^A e^B = e^C, \tag{L.32}$$

where

$$C = A + B + \tfrac{1}{2}[A,B] + \tfrac{1}{12}([A,[A,B]] + [[A,B],B]) + \cdots\,.$$

Special cases:

$$e^A e^B = e^{A+B+\frac{1}{2}[A,B]}\ \text{if } A \text{ and } B \text{ commute with } [A,B] \tag{L.33a}$$

$$e^A B e^{-A} = B + [A,B] + \tfrac{1}{2!}[A,[A,B]] + \tfrac{1}{3!}[A,[A,[A,B]]] + \cdots \tag{L.33b}$$

$$e^A B e^{-A} = B + [A,B]\ \text{if } A \text{ commutes with } [A,B] \tag{L.33c}$$

$$e^A B e^{-A} = e^\gamma B\ \text{if } [A,B] = \gamma B, \text{ with } \gamma \text{ a constant.} \tag{L.33d}$$

Trotter formula:

$$e^{A+B} = \lim_{N\to\infty}(e^{A/N}e^{B/N})^N. \tag{L.34}$$

Zassenhaus formula:

$$e^{A+B} = e^A e^B \prod_{n=2}^{\infty} e^{C_n}, \tag{L.35}$$

where

$$C_2 = -\tfrac{1}{2}[A,B]; \quad C_3 = \tfrac{1}{6}(2[A,[A,B]] - [[A,B],B]).$$

L.9 Legendre polynomials

The associated Legendre differential equation is given by,

$$\left[\left(1-u^2\right)\frac{d^2}{du^2} - 2u\frac{d}{du} - \frac{m^2}{1-u^2} + l(l+1)\right] P_l^m(u) = 0 \tag{L.36}$$

For $m = 0$ this equation is called the Legendre differential equation and its solutions are the Legendre polynomials, defined by the *Rodrigues formula*:

$$P_l(u) = \frac{1}{2^l l!}\frac{d^l}{du^l}(u^2-1)^l. \tag{L.37}$$

$P_l(u)$ is a real polynomial of *degree* $l \in \{0,1,2\cdots\}$, *parity*

$$P_l(-u) = (-1)^l P_l(u) \tag{L.38}$$

and having l zeros in the interval $-1 \le u \le 1$. The Legendre polynomials of lowest degree are

$$P_0(u) = 1, \quad P_1(u) = u, \quad P_2(u) = \tfrac{1}{2}(3u^2-1) \tag{L.39}$$

$$P_3(u) = \tfrac{1}{2}(5u^3-3u), \quad P_4(u) = \tfrac{1}{8}(35u^4-30u^2+3). \tag{L.40}$$

The Legendre polynomials are generated by expansion of the function

$$\frac{1}{|\mathbf{r}-\mathbf{r}'|} = \frac{1}{\sqrt{r^2-2urr'+r'^2}} = \frac{1}{r_>}\sum_l \left(\frac{r_<}{r_>}\right)^l P_l(u), \tag{L.41}$$

where $r_> = \max\{r,r'\}$ and $r_< = \min\{r,r'\}$ with $r = |\mathbf{r}|$ and $r' = |\mathbf{r}'|$; further $u = \hat{\mathbf{r}}\cdot\hat{\mathbf{r}}' = \cos\theta$, with θ the angle included by the unit vectors $\hat{\mathbf{r}}$ and $\hat{\mathbf{r}}'$. The expansion (L.41) is called the *multipole expansion.*

For $m \ne 0$ the solutions of Eq. (L.36) are called the associated Legendre functions $P_l^m(u)$. For $m = 0$ they coincide with the Legendre polynomials. For $m > 0$ the $P_l^m(u)$ are obtained by differentiation of the $P_l(u)$,[1]

$$P_l^m(u) = (-1)^m(1-u^2)^{m/2}\frac{d^m}{du^m}P_l(u). \tag{L.42}$$

Note that $P_l^0(u) \equiv P_l(u)$. The differentiation fixes the relative sign of the polynomials of different power. These functions consist of the product of a function $(-1)^m(1-u^2)^{m/2}$ and a polynomial of degree $(l-m)$, parity $(-1)^{l-m}$ with $(l-m)$ zeros in the interval $-1 \le u \le 1$. For crossing from positive to negative m the sign and normalization are fixed by convention,[2]

$$P_l^{-m}(u) = (-1)^m\frac{(l-m)!}{(l+m)!}P_l^m(u), \tag{L.43}$$

---

[1] Here the phase factor $(-1)^m$ is introduced to simplify the definition of the spherical harmonics. This convention is implemented in *Mathematica* but deviates from the convention used in most texts on quantum mechanics. Beware that differences in phase convention affect the recursion relations (L.48) and (L.49).

[2] Note that the phase factor oscillates like $(-1)^m$ for $m > 0\cdots$ but is always 1 for $m \le 0$. This is the signature of the Condon and Shortley phase convention [28].

where $0 \leq m \leq l$. The $P_l^m(u)$ are nonzero only for $-l \leq m \leq l$; i.e., the index m can assume $2l+1$ possible values for a given value of l. Particular cases are

$$P_l^0(u) = P_l(u), \quad P_l^l(u) = (-1)^{-l}(2l-1)!!(1-u^2)^{l/2}. \tag{L.44}$$

The *orthogonality* of the P_l^m is expressed by

$$\int_{-1}^{1} P_l^m(u) P_{l'}^m(u) du = 0 \qquad (l \neq l') \tag{L.45a}$$

$$\int_{-1}^{1} P_l^m(u) P_l^{m'}(u) du = 0 \qquad (m \neq m'). \tag{L.45b}$$

The *normalization* of the P_l^m is expressed by

$$\int_{-1}^{1} \left[P_l^m(u)\right]^2 du = 2\int_{0}^{1} \left[P_l^m(u)\right]^2 du = \frac{2}{2l+1}\frac{(l+m)!}{(l-m)!}. \tag{L.46}$$

The following recursion *relations* hold for $-l \leq m \leq l$:

$$(2l+1)uP_l^m(u) = (l-m+1)P_{l+1}^m(u) + (l+m)P_{l-1}^m(u) \tag{L.47}$$

$$\sqrt{1-u^2}P_l^{m+1}(u) = -(l-m+1)(l+m)\sqrt{1-u^2}P_l^{m-1}(u) - 2muP_l^m(u) \tag{L.48}$$

and

$$(1-u^2)\frac{d}{du}P_l^m(u) = -luP_l^m(u) + (l+m)P_{l-1}^m(u) \tag{L.49a}$$

$$= (l+1)uP_l^m(u) - (l-m+1)P_{l+1}^m(u) \tag{L.49b}$$

$$= -muP_l^m(u) - \sqrt{1-u^2}P_l^{m+1}(u) \tag{L.49c}$$

$$= +muP_l^m(u) + (l-m+1)(l+m)\sqrt{1-u^2}P_l^{m-1}(u). \tag{L.49d}$$

L.9.1 Spherical harmonics $Y_l^m(\theta, \varphi)$

The *spherical harmonics* are defined as the joint, *normalized* eigenfunctions of $\mathbf{L}^2$ and L_z. Their relation to the associated Legendre polynomials is given by

$$Y_l^m(\theta, \varphi) = \sqrt{\frac{2l+1}{4\pi}\frac{(l-m)!}{(l+m)!}}P_l^m(\cos\theta)e^{im\varphi}, \tag{L.50}$$

with $-l \leq m \leq l$. The *orthonormality relation* is

$$\int Y_l^{m*}(\hat{\mathbf{r}}) Y_{l'}^{m'}(\hat{\mathbf{r}}) d\hat{\mathbf{r}} = \delta_{l'l}\delta_{m'm}. \tag{L.51}$$

Using Eq. (L.43) we find that the *complex conjugation* is given by

$$Y_l^{m*}(\hat{\mathbf{r}}) = (-1)^m Y_l^{-m}(\hat{\mathbf{r}}). \tag{L.52}$$

The *parity* under space inversion, $\hat{\mathbf{r}} = (\theta, \varphi) \to -\hat{\mathbf{r}} = (\pi - \theta, \varphi + \pi)$, is given by

$$Y_l^m(-\hat{\mathbf{r}}) = (-1)^l Y_l^m(\hat{\mathbf{r}}). \tag{L.53}$$

Alternatively, the spherical harmonics can be defined using only associated Legendre functions of positive m,[1]

$$Y_l^m(\theta,\varphi)=\varepsilon\sqrt{\frac{2l+1}{4\pi}\frac{(l-|m|)!}{(l+|m|)!}}P_l^{|m|}(\cos\theta)e^{im\varphi}\quad\text{with}\quad\varepsilon=\begin{cases}(-1)^m & \text{for } m\geq 0\\ 1 & \text{for } m<0.\end{cases}\tag{L.54}$$

Note that the spherical harmonics with even l have even parity and those with odd l have odd parity. The lowest order spherical harmonics are:

$$\left.\begin{array}{rcl}
 & \sqrt{\frac{4\pi}{2l+1}}Y_l^m(\theta,\varphi)-\textit{spherical} & \qquad\sqrt{\frac{4\pi}{2l+1}}Y_l^m(x,y,z)-\textit{cartesian}\\
Y_0^0= & 1 & \Leftrightarrow\; 1\\
Y_1^0= & \cos\theta & \Leftrightarrow\; z/r\\
Y_1^{\pm1}= & \mp\sqrt{\frac{1}{2}}\sin\theta\; e^{\pm i\varphi} & \Leftrightarrow\; \mp\sqrt{\frac{1}{2}}\,(x\pm iy)\,/r\\
Y_2^0= & \frac{1}{2}\left(3\cos^2\theta-1\right) & \Leftrightarrow\; \frac{1}{2}\left(3z^2-r^2\right)/r\\
Y_2^{\pm1}= & \mp\sqrt{\frac{3}{2}}\sin\theta\cos\theta\; e^{\pm i\varphi} & \Leftrightarrow\; \mp\sqrt{\frac{3}{2}}\,(x\pm iy)\,z/r^2\\
Y_2^{\pm2}= & \sqrt{\frac{3}{2}\frac{1}{2}}\sin^2\theta\; e^{\pm 2i\varphi} & \Leftrightarrow\; \sqrt{\frac{3}{2}\frac{1}{2}}\,(x\pm iy)^2\,/r^2\\
Y_3^0= & \frac{1}{2}\left(2\cos^3\theta-3\cos\theta\sin^2\theta\right) & \Leftrightarrow\; \frac{1}{2}\left(5z^2-3r^2\right)z/r^3\\
Y_3^{\pm1}= & \mp\sqrt{\frac{3}{16}}\left(4\cos^2\theta\sin\theta-\sin^3\theta\right)e^{\pm i\varphi} & \Leftrightarrow\; \mp\sqrt{\frac{3}{16}}\,(x\pm iy)\left(5z^2-r^2\right)/r^3\\
Y_3^{\pm2}= & \sqrt{\frac{15}{2}\frac{1}{2}}\cos\theta\sin^2\theta\; e^{\pm 2i\varphi} & \Leftrightarrow\; \sqrt{\frac{15}{2}\frac{1}{2}}\,(x\pm iy)^2\,z/r^3\\
Y_3^{\pm3}= & \mp\sqrt{\frac{5}{2}}\sqrt{\frac{1}{8}}\sin^3\theta\; e^{\pm 3i\varphi} & \Leftrightarrow\; \mp\sqrt{\frac{5}{2}}\sqrt{\frac{1}{8}}\,(x\pm iy)^3\,/r^3.
\end{array}\right\}\tag{L.55}$$

Note that

$$Y_l^m(\theta,\varphi)|_{\grave{\theta}=0}=\sqrt{\frac{2l+1}{4\pi}}\delta_{m,0}.$$

Furthermore, the phase factor oscillates like $(-1)^m$ for $m=1,3,5,\cdots 0$ but is always 1 for $m<0$; this is the signature of the Condon and Shortley phase convention.

The *addition theorem* relates the angle θ_{12} between two directions $\hat{\mathbf{r}}_1=(\theta_1,\varphi_1)$ and $\hat{\mathbf{r}}_2=(\theta_2,\varphi_2)$ relative to a coordinate system of choice,

$$\frac{2l+1}{4\pi}P_l(\cos\theta_{12})=\sum_{m=-l}^{l}Y_l^{m*}(\hat{\mathbf{r}}_1)Y_l^m(\hat{\mathbf{r}}_2).\tag{L.56}$$

The product of two spherical harmonics can be expressed in terms of Wigner $3j$ symbols

$$Y_l^m(\hat{\mathbf{r}})Y_{l'}^{m'}(\hat{\mathbf{r}})=\sum_{L=|l-l'|}^{l+l'}\sum_{M=-L}^{L}(-1)^M\sqrt{\frac{(2l+1)(2l'+1)(2L+1)}{4\pi}}$$
$$\times\begin{pmatrix}l\;l'\;L\\0\;0\;0\end{pmatrix}\begin{pmatrix}l&l'&L\\m&m'&M\end{pmatrix}Y_L^{-M}(\hat{\mathbf{r}}),\tag{L.57}$$

---

[1] Note that the phase factor $(-1)^m$ is only included for positive m. This is the signature of the Condon and Shortley phase convention [28].

An important relation is the *integral over three spherical harmonics* [49]

$$\int Y_{l_1}^{m_1}(\hat{\mathbf{r}})Y_{l_2}^{m_2}(\hat{\mathbf{r}})Y_{l_3}^{m_3}(\hat{\mathbf{r}})d\hat{\mathbf{r}} = \sqrt{\frac{(2l_1+1)(2l_2+1)(2l_3+1)}{4\pi}} \begin{pmatrix} l_1 & l_2 & l_3 \\ 0 & 0 & 0 \end{pmatrix} \begin{pmatrix} l_1 & l_2 & l_3 \\ m_1 & m_2 & m_3 \end{pmatrix}. \tag{L.58}$$

In Dirac notation this becomes

$$\langle l'm'|\, Y_k^q(\hat{\mathbf{r}})\, |lm\rangle = (-1)^{m'} \sqrt{\frac{(2l'+1)(2k+1)(2l+1)}{4\pi}} \begin{pmatrix} l' & k & l \\ 0 & 0 & 0 \end{pmatrix} \begin{pmatrix} l' & k & l \\ -m' & q & m \end{pmatrix}. \tag{L.59}$$

Some special cases are:

- $k = 0$: The $3j$ symbols are zero unless $l' = l$ and $m' = m$; hence, we find
$$\langle l'm'|\, \sqrt{4\pi}\, Y_0^0(\hat{\mathbf{r}})\, |lm\rangle = \delta_{l',l}\delta_{m',m} \tag{L.60}$$
- $k = 1$: The first $3j$ symbol is zero unless $l' = l \pm 1$; hence, we find
$$\langle l'm'|\, \sqrt{4\pi/3}\, Y_1^q(\hat{\mathbf{r}})\, |lm\rangle = (-1)^{m'+\max(l,l')} \sqrt{\max(l,l')} \begin{pmatrix} l' & 1 & l \\ -m' & q & m \end{pmatrix} \delta_{l',l\pm1} \tag{L.61}$$
- $k = 2$: The first $3j$ symbol is zero unless $l' = l,\ l \pm 2$; hence, we find

$$\langle l'm'|\, \sqrt{4\pi/5}\, Y_2^q(\hat{\mathbf{r}})\, |lm\rangle = \begin{cases} (-1)^{m'+l+1} \sqrt{\dfrac{l\,(l+1)\,(2l+1)}{(2l+3)(2l-1)}} \begin{pmatrix} l & 2 & l \\ -m' & q & m \end{pmatrix} & l' = l \\ (-1)^{m'+l} \sqrt{\dfrac{3}{4}\dfrac{l+l'}{l+l'+1}} \sqrt{\max(l,l')} \begin{pmatrix} l' & 2 & l \\ -m' & q & m \end{pmatrix} & l' = l \pm 2. \end{cases} \tag{L.62}$$

L.10 Hermite polynomials

The Hermite differential equation is given by

$$y'' - 2xy' + 2ny = 0. \tag{L.63}$$

For $n = 0, 1, 2, \ldots$ the solutions satisfy the Rodrigues formula

$$H_n(x) = (-1)^n e^{x^2} \frac{d^n}{dx^n}(e^{-x^2}). \tag{L.64}$$

These solutions are polynomials of *degree n* known as *Hermite polynomials.* Examples:

$$\begin{array}{ll} H_0(x) = 1 & H_4(x) = 16x^4 - 48x^2 + 12 \\ H_1(x) = 2x & H_5(x) = 32x^5 - 160x^3 + 120x \\ H_2(x) = 4x^2 - 2 & H_6(x) = 64x^6 - 480x^4 + 720x^2 - 120 \\ H_3(x) = 8x^3 - 12x & H_7(x) = 128x^7 - 1344x^5 + 3360x^3 - 1680x\,. \end{array} \tag{L.65}$$

The generating function is

$$e^{2tx-t^2} = \sum_{n=0}^{\infty} H_n(x) \frac{t^n}{n!}. \tag{L.66}$$

Useful recursion relations are

$$H_{n+1}(x) = 2xH_n(x) - 2nH_{n-1}(x) \tag{L.67}$$

$$H_n'(x) = 2nH_{n-1}(x) \tag{L.68}$$

and the orthogonality relation is given by

$$\int_{-\infty}^{\infty} e^{-x^2} H_m(x)\, H_n(x) = 2^n n! \sqrt{\pi}\, \delta_{mn}\,. \tag{L.69}$$

L.11 Laguerre polynomials

Generalized Laguerre polynomials satisfy the following differential equation

$$xy'' + (\alpha + 1 - x)y' + 2ny = 0. \tag{L.70}$$

For $n = 0, 1, 2, \ldots$ the solutions satisfy the Rodrigues formula[1]

$$L_n^\alpha(x) = \frac{1}{n!} e^x x^{-\alpha} \frac{d^n}{dx^n}(e^{-x} x^{n+\alpha}) \tag{L.71}$$

$$= \sum_{m=0}^{n} (-1)^m \binom{n+\alpha}{n-m} \frac{x^m}{m!}$$

$$= \sum_{m=0}^{n} \frac{\Gamma(\alpha+n+1)}{\Gamma(\alpha+m+1)} \frac{(-1)^m}{(n-m)!} \frac{x^m}{m!} \tag{L.72}$$

These polynomials are well-defined also for real $\alpha > -1$ because the ratio of two gamma functions differing by an integer is well-defined, $(\beta)_n = \beta(\beta+1)(\beta+2)\cdots(\beta+n-1) = \Gamma(\beta+n)/\Gamma(\beta)$. The *Laguerre polynomials* of lowest *degree* are given by

$$L_0^\alpha(x) = 1, \quad L_1^\alpha(x) = \alpha + 1 - x, \quad L_2^\alpha(x) = \tfrac{1}{2}(\alpha+1)(\alpha+2) - (\alpha+2)x + \tfrac{1}{2}x^2. \tag{L.73}$$

Some special cases for $\alpha = 0$ and $\alpha = -n$ are

$$L_0(x) = 1, \quad L_1(x) = 1 - x, \quad L_2(x) = 1 - 2x + \tfrac{1}{2}x^2, \quad L_n^{-n}(x) = (-1)^n \frac{x^n}{n!}. \tag{L.74}$$

The generating function is

$$\frac{(-1)^m t^m}{(1-t)^{m+1}} e^{-x/(1-t)} = \sum_{n=m}^{\infty} L_n^m(x) \frac{t^n}{n!}. \tag{L.75}$$

The generalized Laguerre polynomials satisfy the orthogonality relation

$$\int_0^\infty x^\alpha e^{-x} L_n^\alpha(x) L_m^\alpha(x) dx = 0 \text{ for } m \neq n \text{ (orthogonality relation)} \tag{L.76}$$

$$\int_0^\infty x^\alpha e^{-x} L_n^\alpha(x) dx = \Gamma(\alpha+1)\delta_{0,n}\,. \tag{L.77}$$

Useful recursion relations are:

$$xL_n^\alpha(x) = (2n+\alpha+1)L_n^\alpha(x) - (n+\alpha)L_{n-1}^\alpha(x) - (n+1)L_{n+1}^\alpha \tag{L.78}$$

$$\frac{d}{dx}L_n^\alpha(x) = -L_{n-1}^{\alpha+1}(x) = -[1 + L_1^\alpha(x) + \cdots + L_{n-1}^\alpha(x)]. \tag{L.79}$$

Series expansions:

$$L_n^{\alpha+1}(x) = \sum_{m=0}^{n} L_m^\alpha(x) \tag{L.80a}$$

$$\frac{d}{dx}L_n^\alpha(x) = -\sum_{m=0}^{n-1} L_m^\alpha(x) \tag{L.80b}$$

$$\frac{d^2}{dx^2}L_n^\alpha(x) = \sum_{m=0}^{n-2} (n-m-1)\, L_m^\alpha(x). \tag{L.80c}$$

---

[1] Different definitions can be found in the literature. Here we adhere to the definition of the generalized Laguerre polynomials as used in the *Handbook of Mathematical functions* by Abramowitz and Stegun (Eds.), Dover Publications, New York 1965. This definition is also used by *Mathematica*.

Further, it is practical to introduce a generalized normalization integral

$$J_\nu(m,\alpha)=\int_0^\infty x^{\alpha+\nu}e^{-x}[L_m^\alpha(x)]^2dx. \tag{L.81}$$

Some special cases are given by

$$J_0(m,\alpha)=\int_0^\infty x^{\alpha}e^{-x}[L_m^\alpha(x)]^2dx=\frac{\Gamma(\alpha+m+1)}{m!} \tag{L.82}$$

$$J_1(m,\alpha)=\int_0^\infty x^{\alpha+1}e^{-x}[L_m^\alpha(x)]^2dx=\frac{\Gamma(\alpha+m+1)}{m!}(2m+\alpha+1) \tag{L.83}$$

$$J_2(m,\alpha)=\int_0^\infty x^{\alpha+2}e^{-x}[L_m^\alpha(x)]^2dx=\frac{\Gamma(\alpha+m+1)}{m!}[6m(m+\alpha+1)+\alpha^2+3\alpha+2] \tag{L.84}$$

$$J_{-1}(m,\alpha)=\int_0^\infty x^{\alpha-1}e^{-x}[L_m^\alpha(x)]^2dx=\frac{1}{\alpha}\int_0^\infty x^{\alpha}e^{-x}[L_m^\alpha(x)]^2dx=\frac{\Gamma(\alpha+m+1)}{m!}\frac{1}{\alpha} \tag{L.85}$$

The integrals $J_\nu(m,\alpha)$ with $\nu>0$ are obtained from Eq. (L.82) by repetitive use of the recursion relation (L.78) and orthogonality relation (L.76); integrals $J_\nu(m,\alpha)$ with $\nu<0$ are obtained from Eq. (L.82) by partial integration and use of the recursion relation (L.79), the orthogonality relation (L.76) and the special integral (L.77).
Selected ratios for $m=n-l-1$ and $\alpha=2l+1$:

$$J_4/J_1=\frac{1}{n}[35n^2(n^2-1)-30n^2(l+2)(l-1)+3(l+2)(l+1)l(l-1)] \tag{L.86}$$

$$J_3/J_1=2\left[5n^2+1-3l(l+1)\right] \tag{L.87}$$

$$J_2/J_1=\frac{1}{n}\left[3n^2-l(l+1)\right] \tag{L.88}$$

$$J_1/J_1=1 \tag{L.89}$$

$$J_0/J_1=\frac{1}{2n} \tag{L.90}$$

$$J_{-1}/J_1=\frac{1}{2n}\frac{1}{2l+1} \tag{L.91}$$

$$J_{-2}/J_1=\frac{1}{8}\frac{1}{(l+1)(l+1/2)l} \tag{L.92}$$

$$J_{-3}/J_1=\frac{1}{32n}\frac{3n^2-l(l+1)}{(l+3/2)(l+1)(l+1/2)l(l-1/2)}. \tag{L.93}$$

L.12 Bessel functions

L.12.1 Spherical Bessel functions and Hankel functions

The spherical Bessel differential equation is given by

$$x^2y''+2xy'+\left[x^2-l(l+1)\right]y=0. \tag{L.94}$$

The general solution is a linear combination of two particular solutions, solutions $j_l(x)$, regular (as x^l) at the origin and known as spherical Bessel functions of the first kind, and solutions $n_l(x)$, irregular at the origin and known as spherical Bessel function of the second kind (also called Neumann functions). The spherical Bessel functions and the Neumann functions are real. The general solution can also be written as a linear combination of two complex functions called Hankel functions of the first (+) and second (−) type,

$$h_l^\pm(x)=n_l(x)\pm ij_l(x) \tag{L.95}$$

or, vice versa

$$j_l\,(x) = \frac{1}{2}i\left[h_l^-(x) - h_l^+(x)\right] \tag{L.96a}$$

$$n_l\,(x) = \frac{1}{2}\left[h_l^-(x) + h_l^+(x)\right]. \tag{L.96b}$$

The spherical Bessel functions and Neumann functions are real and Hankel functions can be expressed in the form

$$j_l\,(x) = R_l\frac{\sin x}{x} + S_l\frac{\cos x}{x} \tag{L.97}$$

$$n_l\,(x) = R_l\frac{\sin x}{x} - S_l\frac{\cos x}{x} \tag{L.98}$$

$$h_l^\pm(x) = (R_l \pm iS_l)\,\frac{e^{\pm ix}}{x}, \tag{L.99}$$

where R_l and S_l are polynomials in $1/x$ with real coefficients. In the case of R_l the polynomial is of degree l and has parity $(-1)^l$; the polynomial S_l is of degree $l-1$ and has parity $(-1)^{l-1}$. For real x the polynomial $(R_l \pm iS_l)$ is of the form

$$R_l \pm iS_l = \sum_{s=0}^{l}\frac{(\pm i)^{s-l}}{2^s s!}\frac{(l+s)!}{(l-s)!}\left(\frac{1}{x}\right)^s. \tag{L.100}$$

For real argument x the functions $j_l\,(x)$ and $n_l\,(x)$ are real and the Hankel functions satisfy the relation

$$h_l^\pm(x) = h_l^\mp(x)^*.$$

The parity relations for the spherical Bessel, spherical Neumann and spherical Hankel functions are

$$j_l(-z) = (-1)^l j_l(z) \tag{L.101}$$

$$n_l(-z) = (-1)^{l-1} n_l(z) \tag{L.102}$$

$$h_l^\pm(-z) = (-1)^{l-1} h_l^\mp(z). \tag{L.103}$$

An integral representation of the spherical Bessel function is

$$j_l\,(kr) = \tfrac{1}{2}(-1)^l\int_{-1}^{1} e^{ikr\cos\theta}P_l(\cos\theta)d\cos\theta \tag{L.104}$$

Some special cases are given by

- Lowest orders:

$$\begin{aligned} j_0\,(x) &= \frac{\sin x}{x}, & n_0\,(x) &= \frac{\cos x}{x}, & h_0^\pm(x) &= \frac{e^{\pm ix}}{x},\\ j_1\,(x) &= \frac{\sin x}{x^2} - \frac{\cos x}{x}, & n_1\,(x) &= \frac{\cos x}{x^2} + \frac{\sin x}{x}, & h_1^\pm(x) &= \left(\frac{1}{x^2} \mp i\frac{1}{x}\right)\frac{e^{\pm ix}}{x}. \end{aligned} \tag{L.105a}$$

- Asymptotic forms for $x \to \infty$

$$j_l\,(x) \underset{x\to\infty}{\sim} \frac{1}{x}\sin(x - \tfrac{1}{2}l\pi) \tag{L.106a}$$

$$n_l\,(x) \underset{x\to\infty}{\sim} \frac{1}{x}\cos(x - \tfrac{1}{2}l\pi) \tag{L.106b}$$

$$h_l^\pm(x) \underset{x\to\infty}{\sim} \frac{e^{\pm i(x-\frac{1}{2}l\pi)}}{x}\left[1 \pm i\frac{l(l+1)}{2x}\right]. \tag{L.106c}$$

- Asymptotic forms for $x \to 0$

$$j_l(x) \underset{x\to 0}{\sim} \frac{x^l}{(2l+1)!!}\left[1 - \frac{x^2}{2(2l+3)} + \cdots\right] \tag{L.107a}$$

$$n_l(x) \underset{x\to 0}{\sim} \frac{(2l+1)!!}{(2l+1)}\left(\frac{1}{x}\right)^{l+1}\left[1 + \frac{x^2}{2(2l-1)} + \cdots\right]. \tag{L.107b}$$

- Orthogonality relations

$$\int_0^\infty j_l(k_1 r)\, j_l(k_2 r)\, r^2 dr = \frac{\pi}{2k_1^2}\delta(k_1 - k_2) \tag{L.108}$$

$$\int_{-\infty}^\infty j_l(x)\, j_{l'}(x)\, dx = \frac{\pi}{2l+1}\delta_{l'l}. \tag{L.109}$$

L.12.1.1 Relation to Riccati functions

The Riccati functions $\hat{\jmath}_l(x)$, $\hat{n}_l(x)$ and $\hat{h}_l^{\pm}(x)$ are defined as

$$\hat{\jmath}_l(x) = x j_l(x) \tag{L.110a}$$

$$\hat{n}_l(x) = x n_l(x) \tag{L.110b}$$

$$\hat{h}_l^{\pm}(x) = x h_l^{\pm}(x). \tag{L.110c}$$

L.12.1.2 Relation to Bessel functions

The spherical Bessel functions are related to half-integer Bessel functions

$$j_l(x) = \sqrt{\frac{\pi}{2x}} J_{l+\frac{1}{2}}(x) \text{ for } l = 0, 1, 2, \ldots \tag{L.111}$$

$$n_l(x) = (-)^l \sqrt{\frac{\pi}{2x}} J_{-l-\frac{1}{2}}(x) \text{ for } l = 0, 1, 2, \ldots \tag{L.112}$$

L.12.2 Bessel functions

The Bessel differential equation is given by

$$x^2 y'' + x y' + \left(x^2 - n^2\right) y = 0. \tag{L.113}$$

The general solution is a linear combination of two particular solutions

$$y = A J_n(x) + B J_{-n}(x) \text{ for } n \neq 0, 1, 2, \cdots \tag{L.114a}$$

$$y = A J_n(x) + B Y_n(x) \text{ for all integer } n \tag{L.114b}$$

where A and B are arbitrary constants and $J_{\pm n}(x)$ are Bessel functions, which are defined by

$$J_{\pm n}(x) = \sum_{p=0}^{\infty} \frac{(-1)^p (x/2)^{2p \pm n}}{p!\Gamma(1 + p \pm n)}. \tag{L.115}$$

The $Y_n(x)$ are Neumann functions and are defined by

$$Y_n(x) = \frac{J_n(x)\cos n\pi - J_{-n}(x)}{\sin n\pi} \text{ for } n \neq 0, 1, 2, \cdots \tag{L.116}$$

$$Y_n(x) = \lim_{p\to n} \frac{J_n(x)\cos p\pi - J_{-n}(x)}{\sin p\pi} \text{ for } n = 0, 1, 2, \cdots. \tag{L.117}$$

Extracting the leading term from the Bessel expansion (L.115) results in

$$J_{\pm n}(x) = \frac{(x/2)^{\pm n}}{\Gamma(1 \pm n)} \left(1 - \frac{(x/2)^2}{(1 \pm n)} + \cdots \right). \tag{L.118}$$

The generating function is of the form

$$e^{x(z-1/z)/2} = \sum_{n=-\infty}^{\infty} J_n(x) z^n, \tag{L.119}$$

in particular for $z = 1$

$$\sum_{n=-\infty}^{\infty} J_n(x) = 1.$$

Some differential recursion relations are for any $n \in \mathbb{Z}$

$$2J_n'(x) = J_{n-1}(x) - J_{n+1}(x) \tag{L.120a}$$

$$\frac{2n}{x} J_n(x) = J_{n+1}(x) + J_{n-1}(x) \tag{L.120b}$$

$$\frac{d}{dx}\left[x^n J_n(x)\right] = x^n J_{n-1}(x). \tag{L.120c}$$

Some integral recursion relations are for any $n \in \mathbb{Z}$

$$\int x^{n+1} J_n(x) dx = x^{n+1} J_{n+1}(x) \tag{L.121}$$

$$\int x^{-n+1} J_n(x) dx = -x^{-n+1} J_{n+1}(x). \tag{L.122}$$

Completeness relations for any $m \neq 0$

$$J_0^2(x) + 2\sum_{n=1}^{\infty} J_n^2(x) = 1 \tag{L.123}$$

$$\sum_{n=-\infty}^{\infty} J_{n+m}(x) J_n(x) = 0. \tag{L.124}$$

Addition relation

$$J_n(x+y) \sum_{m=-\infty}^{\infty} J_m(x) J_{n-m}(y) \tag{L.125}$$

Special cases:

Bessel functions with negative integer index

$$J_{-n}(x) = (-1)^n J_n(x) \text{ for } n = 0, 1, 2, \cdots$$
$$Y_{-n}(x) = (-1)^n Y_n(x) \text{ for } n = 0, 1, 2, \cdots .$$

Bessel function of $n = 1/4$

$$J_{1/4}(x) = \frac{(x/2)^{1/4}}{\Gamma(5/4)} (1 - \frac{(x/2)^2 \Gamma(5/4)}{\Gamma(9/4)} + \cdots) \tag{L.126}$$

$$J_{-1/4}(x) = \frac{(x/2)^{-1/4}}{\Gamma(3/4)} (1 - \frac{(x/2)^2 \Gamma(3/4)}{\Gamma(7/4)} + \cdots) \tag{L.127}$$

Asymptotic expansions:

$$J_n(x) \underset{x\to\infty}{\simeq} \sqrt{\frac{2}{\pi}\frac{1}{x}} \cos\left(x - n\frac{\pi}{2} - \frac{\pi}{4}\right) \tag{L.128}$$

$$Y_n(x) \underset{x\to\infty}{\simeq} \sqrt{\frac{2}{\pi}\frac{1}{x}} \sin\left(x - n\frac{\pi}{2} - \frac{\pi}{4}\right) \tag{L.129}$$

Integral expressions for $\mu + \nu + 1 > \lambda > 0$

$$\int_0^\infty \frac{1}{r^\lambda} J_\mu(kr) J_\nu(kr) dr = \frac{k^{\lambda-1}\Gamma(\lambda)\Gamma\left(\frac{\mu+\nu-\lambda+1}{2}\right)}{2^\lambda \Gamma\left(\frac{\mu-\nu+\lambda+1}{2}\right)\Gamma\left(\frac{\mu+\nu+\lambda+1}{2}\right)\Gamma\left(\frac{\nu-\mu+\lambda+1}{2}\right)}. \tag{L.130}$$

Special cases $2\mu + 1 > \lambda > 0$

$$\int_0^\infty \frac{1}{r^\lambda} \left[J_\mu(kr)\right]^2 dr = \frac{k^{\lambda-1}\Gamma(\lambda)\Gamma\left(\frac{2\mu-\lambda+1}{2}\right)}{2^\lambda \left[\Gamma\left(\frac{\lambda+1}{2}\right)\right]^2 \Gamma\left(\frac{2\mu+\lambda+1}{2}\right)}. \tag{L.131}$$

L.12.3 Jacobi-Anger expansion and related expressions

The Jacobi-Anger expansions are is given by

$$e^{iz\cos\theta} = \sum_{n=-\infty}^{n=\infty} i^n J_n(z) e^{in\theta} \tag{L.132}$$

$$e^{iz\sin\theta} = \sum_{n=-\infty}^{n=\infty} i^n J_n(z) e^{in(\theta-\pi/2)} = \sum_{n=-\infty}^{n=\infty} J_n(z) e^{in\theta}, \tag{L.133}$$

where n assumes only integer values. Using $\int_{-\pi}^{\pi} e^{in\alpha} d\alpha = \delta_{n,0}$ this leads to the following integral representation of the Bessel function

$$\int_{-\pi}^{\pi} e^{iz\sin\theta} e^{-im\theta} d\theta = \sum_{n=-\infty}^{n=\infty} J_n(z) \int_{-\pi}^{\pi} e^{in\theta} e^{-im\theta} d\theta = J_n(z), \tag{L.134}$$

in particular

$$J_0(z) = \int_{-\pi}^{\pi} e^{iz\sin\theta} d\theta = \int_{-\pi}^{\pi} e^{iz\cos\theta'} d\theta'. \tag{L.135}$$

This relation can be rewritten in several closely related forms

$$e^{iz\sin\theta} = J_0(z) + \sum_{n=1}^{n=\infty} J_n(z)[e^{in\theta} + (-1)^n e^{-in\theta}] \tag{L.136}$$

$$\cos(z\sin\theta) = \Re(e^{iz\sin\theta}) = J_0(z) + 2\sum_{n=2,4,\cdots}^{n=\infty} J_n(z)\cos(n\theta) \tag{L.137}$$

$$\sin(z\sin\theta) = \Im(e^{iz\sin\theta}) = 2\sum_{n=1,3,\cdots}^{n=\infty} J_n(z)\sin(n\theta). \tag{L.138}$$

L.13 The Wronskian and Wronskian Theorem

Let us consider a second-order differential equation of the following general form

$$\chi'' + F(r)\chi = 0 \tag{L.139}$$

and look for some general properties of this eigenvalue equation. The only restrictions will be that $F(r)$ is bounded from below and continuous over the entire interval $(-\infty, +\infty)$. To compare full solutions of Eq. (L.139) with approximate solutions the analysis of their *Wronskian* is an important tool. The Wronskian of two functions $\chi_1(r)$ and $\chi_2(r)$ is defined as

$$W(\chi_1, \chi_2) \equiv \chi_1\chi_2' - \chi_1'\chi_2. \tag{L.140}$$

Problem L.1. If the Wronskian of two functions $\chi_1(r)$ and $\chi_2(r)$ is vanishing at a given value of r, then the logarithmic derivative of these two functions are equal at that value of r.

Solution. The Wronskian $W(\chi_1, \chi_2)$ is vanishing at position r if $\chi_1\chi_2' - \chi_1'\chi_2 = 0$. This can be rewritten as

$$\frac{d\ln\chi_1}{dr} = \frac{\chi_1'}{\chi_1} = \frac{\chi_2'}{\chi_2} = \frac{d\ln\chi_2}{dr}.$$

Hence, the logarithmic derivatives are equal. □

Problem L.2. Show that the derivative of the Wronskian of two functions $\chi_1(r)$ and $\chi_2(r)$, which are (over an interval $a < r < b$) solutions of two differential equations $\chi_1'' + F_1(r)\chi_1 = 0$ and $\chi_2'' + F_2(r)\chi_2 = 0$, is given by

$$dW(\chi_1, \chi_2)/dr = [F_1(r) - F_2(r)]\chi_1\chi_2.$$

This is the differential form of the Wronskian theorem.

Solution. The two functions $\chi_1(r)$ and $\chi_2(r)$ are solutions (over an interval $a < r < b$) of the equations

$$\chi_1'' + F_1(r)\chi_1 = 0 \tag{L.141}$$
$$\chi_2'' + F_2(r)\chi_2 = 0, \tag{L.142}$$

Multiplying the upper equation by χ_2 and the lower one by χ_1, we obtain after subtracting the two equations

$$dW(\chi_1, \chi_2)/dr = \chi_1\chi_2'' - \chi_2\chi_1'' = [F_1(r) - F_2(r)]\chi_1\chi_2.$$

In integral form this expression is known as the *Wronskian theorem,*

$$W(\chi_1, \chi_2)|_a^b = \int_a^b [F_1(r) - F_2(r)]\chi_1(r)\chi_2(r)dr. \tag{L.143}$$

The Wronskian theorem expresses the overall variation of the Wronskian of two functions over a given interval of their joint variable. □

Problem L.3. Show that the derivative of the Wronskian of two functions $\chi_1(r)$ and $\chi_2(r)$, which are (over an interval $a < r < b$) solutions of two differential equations $\chi_1'' + F_1(r)\chi_1 + f_1(r) = 0$ and $\chi_2'' + F_2(r)\chi_2 + f_2(r) = 0$, is given by

$$dW(\chi_1, \chi_2)/dr = [F_1(r) - F_2(r)]\chi_1\chi_2 + f_1(r)\chi_2 - f_2(r)\chi_1.$$

Solution. The two functions $\chi_1(r)$ and $\chi_2(r)$ are solutions (over an interval $a < r < b$) of the equations

$$\chi_1'' + F_1(r)\chi_1 + f_1(r) = 0 \tag{L.144}$$
$$\chi_2'' + F_2(r)\chi_2 + f_2(r) = 0, \tag{L.145}$$

Multiplying the upper equation by χ_2 and the lower one by χ_1, we obtain after subtracting the two equations

$$dW(\chi_1, \chi_2)/dr = [F_1(r) - F_2(r)]\chi_1\chi_2 + f_1(r)\chi_2 - f_2(r)\chi_1.$$

In integral form this expression becomes

$$W(\chi_1,\chi_2)|_a^b = \int_a^b [F_1(r) - F_2(r)]\chi_1\chi_2 dr + \int_a^b [f_1(r)\chi_2 - f_2(r)]\chi_1 dr. \tag{L.146}$$

The Wronskian theorem expresses the overall variation of the Wronskian of two functions over a given interval of their joint variable. □

For two functions $\chi_1(r,\varepsilon_1)$ and $\chi_2(r,\varepsilon_2)$, which are solutions of the 1D-Schrödinger equation (L.139) on the interval $a < r < b$ for energies ε_1 and ε_2, the Wronskian Theorem takes the form

$$W(\chi_1,\chi_2)|_a^b = (\varepsilon_1 - \varepsilon_2)\int_a^b \chi_1(r)\chi_2(r)dr. \tag{L.147}$$

Likewise, for two functions $\chi_1(r)$ and $\chi_2(r)$, which are (on the interval $a < r < b$) solutions for energy ε of the 1D-Schrödinger equation (L.139) with potential $U_1(r)$ and $U_2(r)$, respectively, the Wronskian Theorem takes the form

$$W(\chi_1,\chi_2)|_a^b = \int_a^b [U_2(r) - U_1(r)]\,\chi_1(r)\chi_2(r)dr. \tag{L.148}$$

L.14 Total differentials and partial derivatives

In this section we consider the function u, which is function of the variables x, y and z,

$$u = u(x,y,z) \tag{L.149}$$

in the presence of a single constraint

$$g(x,y,z) = 0. \tag{L.150}$$

In thermodynamics the constraint is given by the equation of state of the system under consideration. In view of the constraint we can express x, y, z and u in terms of (y,z), (y,z) or (x,y), respectively,

$$z = z(x,y) \quad \text{or} \quad y = y(x,z) \quad \text{or} \quad x = x(y,z) \tag{L.151}$$

$$u = u(x,y) \quad \text{or} \quad u = u(x,z) \quad \text{or} \quad u = x(y,z). \tag{L.152}$$

L.14.1 Total differential

The *total differential* (also called *exact differential*),

$$dz = \left(\frac{\partial z}{\partial x}\right)_y dx + \left(\frac{\partial z}{\partial y}\right)_x dy \tag{L.153}$$

can always be written in the form

$$dz = A(x,y)dx + B(x,y)dy, \tag{L.154}$$

where

$$A(x,y) \equiv \left(\frac{\partial z}{\partial x}\right)_y \quad \text{and} \quad B(x,y) \equiv \left(\frac{\partial z}{\partial y}\right)_x, \tag{L.155}$$

which implies

$$\left(\frac{\partial A}{\partial y}\right)_x = \left(\frac{\partial B}{\partial x}\right)_y = \frac{\partial^2 z}{\partial x \partial y}. \tag{L.156}$$

Properties:

Path invariance: The integral $\int A(x,y)dx + \int B(x,y)dy$ is independent of the integration path in the x, y plane but only depends on the value of the function z at the beginning and the end point,

$$\int_{x_1,y_1}^{x_2,y_2} A(x,y)dx + \int_{x_1,y_1}^{x_2,y_2} B(x,y)dy = \int_{z_1}^{z_2} dz = z_2 - z_1, \tag{L.157}$$

where $z_1 = z(x_1, y_1)$ and $z_2 = z(x_2, y_2)$.

Minus 1 rule: The variables x, y, z satisfy the relation (see Problem L.4)

$$\left(\frac{\partial x}{\partial y}\right)_z \left(\frac{\partial y}{\partial z}\right)_x \left(\frac{\partial z}{\partial x}\right)_y = -1. \tag{L.158}$$

Problem L.4. Derive the minus 1 rule.

Solution. This rule follows by substituting the total differential

$$dy = \left(\frac{\partial y}{\partial x}\right)_z dx + \left(\frac{\partial y}{\partial z}\right)_x dz \tag{L.159}$$

into Eq. (L.153)

$$dz = \left(\frac{\partial z}{\partial x}\right)_y dx + \left(\frac{\partial z}{\partial y}\right)_x \left(\frac{\partial y}{\partial x}\right)_z dx + \left(\frac{\partial z}{\partial y}\right)_x \left(\frac{\partial y}{\partial z}\right)_x dz. \tag{L.160}$$

Since

$$\left(\frac{\partial z}{\partial y}\right)_x \left(\frac{\partial y}{\partial z}\right)_x = 1 \tag{L.161}$$

the differential is only satisfied if

$$\left(\frac{\partial z}{\partial x}\right)_y + \left(\frac{\partial z}{\partial y}\right)_x \left(\frac{\partial y}{\partial x}\right)_z = 0, \tag{L.162}$$

which can be rewritten in the form of the *minus 1 rule.* □

Inversely, the expression (L.154) is in general *not* a total differential. Interpreting $A(x,y)$ and $B(x,y)$ as partial derivatives,

$$A(x,y) \equiv \left(\frac{\partial z_A}{\partial x}\right)_y \quad \text{and} \quad B(x,y) \equiv \left(\frac{\partial z_B}{\partial y}\right)_x, \tag{L.163}$$

we find that in general

$$\left(\frac{\partial A}{\partial y}\right)_x \neq \left(\frac{\partial B}{\partial x}\right)_y. \tag{L.164}$$

For this case we use the notation:

$$đz = A(x,y)dx + B(x,y)dy. \tag{L.165}$$

Only if the condition (L.156) holds the functions $z_A(x,y)$ and $z_B(x,y)$ are equal (up to a constant) and Eq. (L.154) becomes a total differential.

M

Square matrices

M.1 Nomenclature and notation

In this section we summarize the nomenclature and properties of *complex* square matrices of *order* n. An arbitrary $n \times n$ matrix A and its *inverse* are written as

$$A \equiv (a^i_j) \text{ and } A^{-1} \equiv (a^i_j)^{-1} \equiv (\bar{a}^i_j), \tag{M.1}$$

where a^i_j and $\bar{a}^i_j$ represent the elements of these matrices with the convention that the *upper* or *contravariant* index is the *row* index and the *lower* or *covariant* index is the *column* index. We define the index order, *upper precedes lower.* Conforming to the standard matrix notation, the *first* index is the *row* index of the matrix (a^i_j) and the *second* index the *column* index. The *transposed* matrix

$$A^T \equiv \tilde{A} \equiv (\tilde{a}^i_j) = (a^j_i) \tag{M.2}$$

is obtained by exchanging rows and columns, the *complex conjugate*

$$A^* \equiv (a^i_j)^* = (a^{i*}_j) \tag{M.3}$$

by taking the complex conjugate of all elements, and the *hermitian conjugate* or *conjugate transpose*

$$A^\dagger \equiv (a^i_j)^\dagger = (a^{j*}_i) = \tilde{A}^* \tag{M.4}$$

is obtained by complex conjugation of the transposed matrix. The trace of the matrix A is defined as

$$\mathrm{tr}A = \sum_{i=1}^{n} a^i_i. \tag{M.5}$$

The determinant of the matrix A is defined by the *Leibniz expansion*

$$|A| \equiv \det A = \det(a^i_j) = \sum_P (-1)^p a^{i_1}_1 \cdots a^{i_n}_n = \varepsilon_{i_1,\cdots i_n} a^{i_1}_1 \cdots a^{i_n}_n, \tag{M.6}$$

where the summation runs over all permutations P of the indices $(i_1, \cdots i_n) = (1, \cdots n)$ and $p \in \{\text{even}, \text{odd}\}$ is the order of the permutation; $\varepsilon_{i_1,\cdots i_n}$ is a generalized Levi-Civita symbol.

With each element a^i_j of the matrix we can associate a *cofactor*, cofactor(a^i_j), which is defined as the *minor* (sub-determinant) $\det A^i_j$ corresponding to the sub-matrix A^i_j of that element, including its sign $(-1)^{i+j}$. The determinant $\det A$ can be expanded in terms of its minors $\det A^i_j$, *c.q.* cofactors, with respect to row i,

$$\det A = \sum_{i=1}^{n} (-1)^{i+j} a^i_j \det A = \sum_{i=1}^{n} a^i_j \mathrm{cofactor}(a^i_j). \tag{M.7}$$

This is called the *Laplace expansion.* Replacing the elements of the transposed matrix by their cofactors we obtain the *adjoint* matrix, in which the elements are the cofactors of the *transposed* matrix

$$\mathrm{Adj}(a^i_j) = \mathrm{cofactor}(a^j_i) = (-1)^{i+j}\det A^j_i. \tag{M.8}$$

For square matrices we define the following special cases:

$$\begin{array}{llrcl}
\textit{complex:} & \textit{hermitian} & A = A^{\dagger} & \Leftrightarrow & a^i_j = a^{j*}_i \\
 & \textit{unitary} & A^{-1} = A^{\dagger} & \Leftrightarrow & \bar{a}^i_j = a^{j*}_i \\
 & \textit{real} & A = A^{*} & \Leftrightarrow & a^i_j = a^{i*}_j \\
\textit{real:} & \textit{symmetrical} & A = \tilde{A} & \Leftrightarrow & a^i_j = a^j_i \\
 & \textit{orthogonal} & A^{-1} = \tilde{A} & \Leftrightarrow & \bar{a}^i_j = a^j_i
\end{array}
\begin{array}{r}
(\mathrm{M.9}) \\ (\mathrm{M.10}) \\ (\mathrm{M.11}) \\ (\mathrm{M.12}) \\ (\mathrm{M.13})
\end{array}$$

M.2 Properties

If the inverse exists, the matrix A satisfies the following properties:

- The determinant of an $n \times n$ matrix (a^j_i) is invariant under addition to a given column (or row) a scalar multiple of *another* column (or rows)

  $$\begin{vmatrix} a^1_1 \cdots a^n_1 \\ \vdots \quad\ \vdots \\ a^1_n \cdots a^n_n \end{vmatrix} = \begin{vmatrix} a^1_1 + k a^j_1 \cdots a^n_1 \\ \vdots \qquad\quad \vdots \\ a^1_n + k a^j_1 \cdots a^n_n \end{vmatrix} = \begin{vmatrix} a^1_1 & \cdots & a^n_1 \\ \vdots & & \vdots \\ a^1_n + k a^1_i & \cdots & a^n_n + k a^n_i \end{vmatrix}. \tag{M.14}$$

- The determinant of a *triangular* $n \times n$ matrix (a^j_i), *i.e.* $a^j_i = 0$ for $i > j$ (or $j > i$), is equal to the product of the diagonal elements,

  $$\begin{vmatrix} a^1_1 \cdots a^n_1 \\ 0 \ \ddots \ \vdots \\ 0 \ \ 0 \ \ a^n_n \end{vmatrix} = \prod_{i=1}^{n} a^i_i\,. \tag{M.15}$$

  This follows from the Leibniz expansion because the only nonzero product of n matrix elements is the diagonal one.

- The determinant of the blockdiagonal $(n+m) \times (n+m)$ matrix of the $n \times n$ matrix A and the $m \times m$ matrix B is equal to the product of the determinants of the matrices A and B,

  $$\begin{vmatrix} A\,C \\ 0\ B \end{vmatrix} = \begin{vmatrix} a^1_1 \cdots a^n_1 & c^1_1 \cdots c^m_1 \\ \vdots \qquad \vdots & \vdots \qquad \vdots \\ a^1_n \cdots a^n_n & c^1_n \cdots c^m_m \\ & b^1_1 \cdots b^m_1 \\ 0 & \vdots \qquad \vdots \\ & b^1_m \cdots b^m_m \end{vmatrix} = \det A \det B. \tag{M.16}$$

  This follows from the Leibniz expansion because the only nonzero product of $n+m$ matrix elements are the ones containing only elements of the submatrices A and B. Note that the r.h.s. is independent of C because the elements of the submatrix C appear in the determinant only in combination with elements of the zero block.

- The product rule for the determinants of two $n \times n$ matrices, A and B,

  $$\det AB = \det A \, \det B. \tag{M.17}$$

- The determinant of A is non-zero

  $$\det A = \det(a^i_j) = \Delta \neq 0. \tag{M.18}$$

  Proof: Because the inverse exists, $(\bar{a}^i_j) = (a^i_j)^{-1}$, we have $(a^i_j)(\bar{a}^i_j) = \mathbb{1}$. Thus we obtain with the aid of the product rule $1 = \det[(a^i_j)(\bar{a}^i_j)] = \Delta \det(\bar{a}^i_j)$. This implies $\Delta \neq 0$.

- The determinant of A^{-1} equals the inverse of the determinant of A,

  $$\det A^{-1} = \det(\bar{a}^i_j) = \Delta^{-1}. \tag{M.19}$$

  Proof: Because the inverse exists we have (with the aid of the product rule) $1 = \det[(a^i_j)(\bar{a}^i_j)] = \Delta \det(\bar{a}^i_j)$ with $\Delta \neq 0$. This can be rewritten in the form (M.19).

- The determinant of A^* equals the complex conjugate of $\det A$,

  $$\det A^* = \det(a^{i*}_j) = \det(a^i_j)^* = \Delta^*. \tag{M.20}$$

  Proof: $\det(a^{i*}_j) = \varepsilon_{i_1,\cdots i_n} a^{i_1 *}_1 \cdots a^{i_n *}_n = (\varepsilon_{i_1,\cdots i_n} a^{i_1}_1 \cdots a^{i_n}_n)^* = [\det(a^i_j)]^*$.

- The determinant of A is invariant under transposition

  $$\det \tilde{A} = \det A. \tag{M.21}$$

  Proof: $\det(a^i_j) = \varepsilon_{i_1,\cdots i_n} a^{i_1 *}_1 \cdots a^{i_n *}_n = \varepsilon_{i_1,\cdots i_n} a^1_{i_1} \cdots a^n_{i_n} = \det(a^j_i)$.

- *Kronecker property:*

  $$a^i_k \bar{a}^k_j = \delta^i_j \text{ and } \bar{a}^i_{i'} a^{i'}_j = \delta^i_j \tag{M.22}$$

  Proof:[1] $\mathbb{1} = (a^i_j)(\bar{a}^i_j) = (a^i_k \bar{a}^k_j) \Rightarrow (a^i_k \bar{a}^k_j) = \delta^i_j$ and $\mathbb{1} = (\bar{a}^i_j)(a^i_j) = (\bar{a}^i_k a^k_j) \Rightarrow \bar{a}^i_k a^k_j = \delta^i_j$.

- The elements of the inverse matrix are given by

  $$\bar{a}^i_j = \Delta^{-1} \mathrm{Adj}(a^i_j), \tag{M.23}$$

  where $\mathrm{Adj}(a^i_j)$ is the *adjoint* matrix of (a^i_j), *i.e.* $\mathrm{Adj}(a^i_j) = \mathrm{cofactor}(a^j_i) = (-1)^{i+j} \det(A^j_i)$. *Proof:* Let $B = (\alpha^i_j) = \mathrm{Adj}(a^i_j)$ be the *adjoint* matrix of (a^i_j). Then, the product of the matrices A and B is given by

  $$AB = (a^i_j)(\alpha^i_j) = (a^i_k \alpha^k_j) = \sum_{i=1}^{n} a^i_k \mathrm{cofactor}(a^j_k) = (\delta^i_j) \det A = \mathbb{1}\, \Delta. \tag{M.24}$$

  To arrive at the result we used Eq. (M.7) and further $\sum_{i=1}^{n} a^i_k \mathrm{cofactor}(a^j_k) = 0$ for $i \neq j$.[2] Rewriting Eq. (M.24) we obtain at $A^{-1} = B/\Delta$, which had to be proven.

---

[1] Note that $a^i_k b^k_j \neq a^k_i b^j_k$. Therefore we need a convention. In matrix multiplication we use the *column on row* summation convention $(c^i_j) = (a^i_j)(b^i_j) = (a^i_k b^k_j)$. This means that we sum over the column index of the left matrix and the row index of the right matrix.

[2] Note that this expression corresponds to a determinant with two identical columns.

- The trace of the commutator of two $(n \times n)$ matrices, A and B, is zero,
$$\operatorname{tr}[A,B] = 0 \tag{M.25}$$
Proof: The trace $\operatorname{tr} AB$ of the product of the matrices A and B is given by
$$\operatorname{tr} AB = \operatorname{tr}(a_k^i b_j^k) = \sum_{i,k=1}^{n} a_k^i b_i^k = \sum_{i,k=1}^{n} b_i^k a_k^i = \operatorname{tr}(b_i^k a_l^i) = \operatorname{tr} BA.$$
Since $[A,B] = AB - BA$ and $\operatorname{tr}(A+B) = \operatorname{tr}A + \operatorname{tr}B$ this completes the proof.

- The trace of the product of three $(n \times n)$ matrices A, B and C is invariant under cyclic permutation of these matrices,
$$\operatorname{tr} ABC = \operatorname{tr} CAB = \operatorname{tr} BCA \tag{M.26}$$
Proof: This follows by direct application of property M.25.

M.2.1 Unitary matrices

Let $U = (u_i^{i'})$ be a unitary $n \times n$ matrix, $U^{-1} = U^\dagger \equiv \tilde{U}^* \Leftrightarrow \bar{u}_{i'}^{i} = u_i^{i'*}$. The unitarity implies the following properties:

- *Kronecker property*: The Kronecker property takes the following form
$$u_i^{i'*} u_{j'}^{i} = \delta_{j'}^{i'} \text{ and } u_{i'}^{i} u_j^{i'*} = \delta_j^i. \tag{M.27}$$
Proof: Substituting the unitarity condition $\bar{u}_{i'}^{i} = u_i^{i'*}$ in Eq. (M.22) yields the desired result.

- *Determinant* - The determinant of a unitary $n \times n$ matrix U equals a complex number of unit norm,
$$\Delta \equiv \det U = e^{i\varphi}. \tag{M.28}$$
where $\varphi \in \mathbb{R}$. For the special case $\varphi = 0$ the matrix U is called the *special unitary matrix.*
Proof: Using the properties M.20, M.30 and M.19 we find $\Delta^* = \det U^* = \det U^\dagger = \det U^{-1} = 1/\Delta \rightarrow |\Delta|^2 = 1$, which implies (M.28).

- *Matrix inversion rule*: The elements of the inverse matrix are given by
$$u_{i'}^{i*} = e^{-i\varphi}\text{cofactor}(u_i^{i'}), \tag{M.29}$$
Proof: This follows from Eq. (M.23) by substitution of $\Delta = e^{i\varphi}$.

- *Determinant of hermitian conjugate*: The determinant of $U^\dagger$ follows with Eq. (M.21),
$$\det U^\dagger = \det \tilde{U}^* = \det U^* = e^{-i\varphi}. \tag{M.30}$$
Proof: This follows from Eq. (M.21) and substitution of $\Delta = e^{i\varphi}$.

- *Invariance of determinant under unitary transformation:* The determinant of an arbitrary $n \times n$ matrix A is invariant under unitary transformation
$$\det UAU^\dagger = \det A. \tag{M.31}$$
Proof: Using the properties M.17 and M.28 we find det $UAU^\dagger) = \det U \det A \det U^\dagger = e^{i\varphi} \det A \, e^{-i\varphi} = \det A$.

- *Invariance of trace under unitary transformation:* The trace of an arbitrary $n \times n$ matrix A is invariant under unitary transformation
$$\operatorname{tr} UAU^\dagger = \operatorname{tr}A. \tag{M.32}$$
Proof: Using the properties M.26 and M.10 we find $\operatorname{tr} UAU^\dagger = \operatorname{tr} U^\dagger UA = \operatorname{tr} U^{-1}UA = \operatorname{tr}A$.

Vector relations

N.1 Inner and outer products

$$
\begin{aligned}
(\mathbf{u},\mathbf{v},\mathbf{w}) &= \mathbf{u}\cdot(\mathbf{v}\times\mathbf{w}) = \mathbf{v}\cdot(\mathbf{w}\times\mathbf{u}) = \mathbf{w}\cdot(\mathbf{u}\times\mathbf{v}) \qquad &(\text{N.1})\\
\mathbf{u}\times(\mathbf{v}\times\mathbf{w}) &= (\mathbf{u}\cdot\mathbf{w})\mathbf{v} - (\mathbf{u}\cdot\mathbf{v})\mathbf{w} &(\text{N.2})\\
\mathbf{u}\times(\mathbf{v}\times\mathbf{w}) &= -\,(\mathbf{v}\times\mathbf{w})\times\mathbf{u} &(\text{N.3})\\
(\mathbf{u}\times\mathbf{v})\cdot(\mathbf{w}\times\mathbf{z}) &= (\mathbf{u}\cdot\mathbf{w})(\mathbf{v}\cdot\mathbf{z}) - (\mathbf{u}\cdot\mathbf{z})(\mathbf{v}\cdot\mathbf{w}) &(\text{N.4})
\end{aligned}
$$

N.2 Gradient, divergence and curl

N.2.1 Helmholtz theorem

Any vector $\mathbf{A}$ can be separated in an *irrotational* part $\mathbf{A}_{\parallel}$ and a *rotational (solenoidal)* part $\mathbf{A}_{\perp}$, defined by

$$\mathbf{A} = \mathbf{A}_{\perp} + \mathbf{A}_{\parallel} \text{ with } \boldsymbol{\nabla}\cdot\mathbf{A}_{\perp} = 0 \text{ and } \boldsymbol{\nabla}\times\mathbf{A}_{\parallel} = 0. \tag{N.5}$$

N.2.2 Vector identities with a single vector differential operator

$$
\begin{aligned}
\boldsymbol{\nabla}\cdot(\mathbf{A}\phi) &= (\mathbf{A}\cdot\boldsymbol{\nabla}\phi) + \phi(\boldsymbol{\nabla}\cdot\mathbf{A}) \qquad &(\text{N.6})\\
\boldsymbol{\nabla}\times(\mathbf{A}\phi) &= -(\mathbf{A}\times\boldsymbol{\nabla}\phi) + \phi(\boldsymbol{\nabla}\times\mathbf{A}) &(\text{N.7})\\
\boldsymbol{\nabla}\cdot(\mathbf{A}\times\mathbf{B}) &= \mathbf{B}\cdot(\boldsymbol{\nabla}\times\mathbf{A}) + \mathbf{A}\cdot(\boldsymbol{\nabla}\times\mathbf{B}) &(\text{N.8})\\
\boldsymbol{\nabla}\times(\mathbf{A}\times\mathbf{B}) &= (\mathbf{B}\cdot\boldsymbol{\nabla})\mathbf{A} - \mathbf{B}(\boldsymbol{\nabla}\cdot\mathbf{A}) - (\mathbf{A}\cdot\boldsymbol{\nabla})\mathbf{B} + \mathbf{A}(\boldsymbol{\nabla}\cdot\mathbf{B}) &(\text{N.9})\\
\boldsymbol{\nabla}(\mathbf{A}\cdot\mathbf{B}) &= (\mathbf{B}\cdot\boldsymbol{\nabla})\mathbf{A} + (\mathbf{A}\cdot\boldsymbol{\nabla})\mathbf{B} + \mathbf{B}\times(\boldsymbol{\nabla}\times\mathbf{A}) + \mathbf{A}\times(\boldsymbol{\nabla}\times\mathbf{B}) &(\text{N.10})
\end{aligned}
$$

Examples:

$$
\begin{aligned}
\boldsymbol{\nabla}\cdot\mathbf{r} = 3 &\Leftrightarrow \partial_i r_i = 3 \qquad &(\text{N.11})\\
\boldsymbol{\nabla}\times\mathbf{r} = \mathbf{0} &\Leftrightarrow \varepsilon_{ijk}\partial_j r_k = \mathbf{0} &(\text{N.12})\\
(\mathbf{A}\cdot\boldsymbol{\nabla})\mathbf{r} = \mathbf{A} &\Leftrightarrow A_i\nabla_i r_k = A_k &(\text{N.13})\\
\boldsymbol{\nabla}\cdot\dot{\mathbf{r}} = \boldsymbol{\nabla}\times\dot{\mathbf{r}} &= (\mathbf{A}\cdot\boldsymbol{\nabla})\dot{\mathbf{r}} = \mathbf{0} &(\text{N.14})
\end{aligned}
$$

Combining Eqs. (N.10), (N.12) and (N.13) we find

$$\boldsymbol{\nabla}(\mathbf{r}\cdot\mathbf{A}) = \mathbf{A} + (\mathbf{r}\cdot\boldsymbol{\nabla})\mathbf{A} + \mathbf{r}\times(\boldsymbol{\nabla}\times\mathbf{A}). \tag{N.15}$$

Likewise we find by combining Eqs. (N.10) with Eq. (N.9)

$$\boldsymbol{\nabla}(\dot{\mathbf{r}}\cdot\mathbf{A}) = (\dot{\mathbf{r}}\cdot\boldsymbol{\nabla})\mathbf{A} + \dot{\mathbf{r}}\times(\boldsymbol{\nabla}\times\mathbf{A}) \tag{N.16}$$

$$\frac{d}{dt}\mathbf{A} = \frac{\partial}{\partial t}\mathbf{A} + (\dot{\mathbf{r}}\cdot\nabla)\mathbf{A}. \tag{N.17}$$

Special case:

$$\boldsymbol{\nabla} r^n = nr^{n-1}\left(\mathbf{r}/r\right) = nr^{n-1}\hat{\mathbf{r}}. \tag{N.18}$$

For $n \geq 0$ this expression is valid everywhere, including the origin. For $n < 0$ the expression is irregular in the origin. In particular we have

$$\boldsymbol{\nabla}\frac{1}{r} = -\frac{\mathbf{r}}{r^3}. \tag{N.19}$$

Since

$$\boldsymbol{\nabla}|\mathbf{r}-\mathbf{r}'| = \frac{\mathbf{r}-\mathbf{r}'}{|\mathbf{r}-\mathbf{r}'|} = -\boldsymbol{\nabla}'|\mathbf{r}-\mathbf{r}'| \tag{N.20}$$

(as is easily verified in cartesian coordinates) we can generalize Eq. (N.18) to

$$\boldsymbol{\nabla}|\mathbf{r}-\mathbf{r}'|^n = n|\mathbf{r}-\mathbf{r}'|^{n-1}\frac{\mathbf{r}-\mathbf{r}'}{|\mathbf{r}-\mathbf{r}'|} = -\boldsymbol{\nabla}'|\mathbf{r}-\mathbf{r}'|^n. \tag{N.21}$$

N.2.3 Expressions with second derivatives

$$\boldsymbol{\nabla}\times(\boldsymbol{\nabla}\phi) = 0 \tag{N.22}$$

$$\boldsymbol{\nabla}\cdot(\boldsymbol{\nabla}\times\mathbf{A}) = 0 \tag{N.23}$$

$$\boldsymbol{\nabla}\times(\boldsymbol{\nabla}\times\mathbf{A}) = \boldsymbol{\nabla}(\boldsymbol{\nabla}\cdot\mathbf{A}) - \boldsymbol{\nabla}^2\mathbf{A} \tag{N.24}$$

Expressions for the laplacian:

$$\Delta r^n = \boldsymbol{\nabla}\cdot\boldsymbol{\nabla} r^n = nr^{n-2}\left(\boldsymbol{\nabla}\cdot\mathbf{r}\right) + n\mathbf{r}\cdot\boldsymbol{\nabla} r^{n-2} = 3nr^{n-2} + n(n-2)r^{n-2}. \tag{N.25}$$

We distinguish three cases:

$$\Delta r^n = n(n+1)r^{n-2} \quad \text{is regular everywhere} \quad \begin{cases} \text{for } n \geq 0 \ \textit{also} \text{ at the origin} \\ \text{for } n < 0 \ \textit{outside} \text{ at the origin} \end{cases} \tag{N.26}$$

Note that for $n = -1$ this expression yields $\boldsymbol{\nabla}^2(1/r) = 0$ everywhere outside the origin. The case $n = -1$ is special at the origin because the laplacian produces a flux out of any sphere centered around the origin. With the Gauss divergence theorem we calculate for this flux

$$-\int \boldsymbol{\nabla}\left(1/r^3\right)\mathbf{r}\cdot d\mathbf{r} = -\oint\left(1/r^3\right)\mathbf{r}\cdot\hat{\mathbf{r}}dS = -4\pi. \tag{N.27}$$

Thus, Δr^{-1} can be regarded as a distribution and we write

$$\boldsymbol{\nabla}^2(1/r) = -4\pi\delta(\mathbf{r}). \tag{N.28}$$

1 Quantum motion in a central potential field

Het eerste hoofdstuk gaat over de Schrödinger vergelijking voor een deeltje in een centraal potentiaalveld. Het is voor een groot deel een herhaling van wat al bij andere colleges aan de orde is geweest. Je leert hoe de Schrödinger wordt opgesteld en door scheiding van variabelen gereduceerd tot een 1D vergelijking voor de radiale beweging (de radiale golfvergelijking) en een tweetal eigenwaardenvergelijkingen voor de rotatie rond het potentiaalcentrum. Van deze twee vergelijkingen hangt alleen de radiale golfvergelijking af van de potentiaal. De vergelijkingen voor de rotatie zijn voor alle centraalsymmetrische systemen hetzelfde. De rotatie-eigenwaarden liggen vast met de quantumgetallen l en m. De bijbehorende eigenfuncties zijn de bolfuncties. Tot slot bespreken we invariantie van de hamiltoniaan onder draaiing in relatie tot impulsmoment als een behouden grootheid.

Thuis bestuderen:

Hoofdstuk 1: Lees de introductie. Neem kennis van de begrippen centrale potentiaal $\mathcal{V}(r)$, met $r = |\mathbf{r}_1 - \mathbf{r}_2|$ als afstand tussen twee deeltjes, en de gereduceerde massa m_r. Bij dit eerste hoofdstuk is het vooral zaak om het overzicht te behouden. Het is wellicht goed om je parate kennis van de kwantummechanica op te frissen. Hierbij kan Appendix F je helpen. Problem F.1 is heel belangrijk. Problems 1.2, 1.3, 1.5, 1.7, 1.8, 1.9 zijn keuzeopgaven en bedoeld ter verdieping van de stof; blijf hierin niet hangen voordat je het overzicht over het hele hoofdstuk hebt. Ook de stukjes over *cilinder coördinaten* zijn facultatief en vallen buiten de stof.

§ 1.1: Het algemene deel van deze sectie gaat over het opstellen van de *klassieke hamiltoniaan* H_0 en het splitsen daarvan in *radiale* en *rotationele* kinetische energie. Begrijp de begrippen *radiale impuls* p_r en *impulsmoment* $\mathbf{L}$ t.o.v. het potentiaalcentrum. Fris je kennis op van de *Einstein notatie* en *sommatieconventie* en maak Problem 1.1.

- § 1.1.1: We kwantiseren de hamiltoniaan in de *plaatsrepresentatie* gebruik makend van de *correspondentieregels* voor plaats en impuls. We bepalen de *commutatierelaties in cartesische coördinaten* (door gebruik te maken van een testfunctie ϕ); wees je bewust van mogelijke problemen bij het toepassen van de correspondentieregels bij producten van *niet-commuterende operatoren.* We buiten de centrale symmetrie uit door het kiezen *bolcoördinaten.* Schrijf de laplaciaan in bolcoördinaten. De stukjes over *cilinder coördinaten* zijn facultatief.
- § 1.1.2: Opstellen van de operator voor het impulsmoment $\mathbf{L}$ (in de plaatsrepresentatie met orthogonale coördinaten, *cartesiaans* of *kromlijnig*). Uitschrijven van $\mathbf{L}$ in (orthogonale) kromlijnige coördinaten: *bolcoördinaten.*
- § 1.1.3: Oplossen *eigenwaardenvergelijking* voor L_z
- § 1.1.4: Begrijp het nut van *communicator algebra.* Hiermee kunnen we commutatierelaties afleiden voor L_x, L_y, L_z en $\mathbf{L}^2$ zonder gebruik te maken van een testfunctie. Problem 1.4 is heel leerzaam.
- § 1.1.5: Idem voor $L_\pm$. Herschrijf $\mathbf{L}^2$ in termen van L_+, L_- en L_z.
- § 1.1.6: Oplossen eigenwaardenvergelijking voor $\mathbf{L}^2$ (begrijpen van het principe van *scheiding van variabelen*). De details van de $P_l^m(u)$ zijn facultatief. De werking van $L_\pm$ als ladderoperator moet je goed begrijpen maar de gedetailleerde consequenties voor de bolfuncties niet. Weet dat het positieve teken vóór de wortelformule bekend staat als de *Condon en Shortley faseconventie.* Begrijp dat deze conventie ervoor zorgt dat de ladderoperatoren goed werken zowel voor positieve als negatieve waarden van het kwantumgetal m.
- § 1.1.7: Begrijp het gebruik van impulsmoment in de representatievrije notatie van *Dirac.*

- § 1.1.8: Begrijp het afleiden van een uitdrukking voor de radiale impuls, p_r, en commutatierelaties voor p_r en p_r^2. Problem 1.5 is facultatief maar Problem 1.6 is heel nuttig (voor 2D facultatief).

§ 1.2: Schrödinger vergelijking

- § 1.2.1: Opstellen van *3D Schrödinger vergelijking* voor de golffunctie $\psi_{lm}(r)$ voor een deeltje in een centraal potentiaalveld gebruik makend van bolcoördinaten. Reductie van de 3D Schrödinger vergelijking tot de 1D *radiale golfvergelijking* voor de radiale golffunctie $R_l(r)$ voor gegeven impulsmoment l, plus de 2D Schrödinger vergelijking voor de rotatiegolffunctie $Y_{lm}(\hat{\mathbf{r}})$, met $\hat{\mathbf{r}} = (\theta, \phi)$, die de rotatiebeweging rond het potentiaalcentrum beschrijft. Begrijp de *scheiding van variabelen.* Herschrijven van de radiale golfvergelijking in de vorm van een *1D Schrödinger vergelijking* met een *gereduceerde* golffunctie $\chi_l(r) = rR_l(r)$. Problems 1.7-1.9 zijn facultatief.
- § 1.2.2: Idem voor cilinder coördinaten. Deze paragraaf is facultatief.

§ 1.3: Lees deze paragraaf zorgvuldig door. Begrijp wat er bedoeld wordt met pariteit. Begrijp ook dat het commuteren van de operatoren $\partial/\partial\phi$ en $\mathcal{H}_0$ impliceert dat $\mathcal{H}_0$ invariant is onder rotatie rond de z as.

Parate kennis:

1. De naam en definitie van de grootheden m_r, p_r, $\mathbf{L}$, $L_\pm$, $\mathcal{V}_{\text{rot}}(r)$, Z, l, m, $\chi_l(r)$.
2. De uitdrukking voor de impulsoperator, $p_i = i\hbar\partial_i$ en afleiding $[r_i, p_j] = i\hbar\delta_{ij}$ met testfunctie.
3. De commutatierelaties voor L_x, L_y en L_z en hun afleiding zonder testfunctie.
4. De inproductregel $\mathbf{L}^2 = \mathbf{L}\cdot\mathbf{L} = L_zL_z + \frac{1}{2}(L_+L_- + L_-L_+)$ met $L_\pm = L_x \pm iL_y$.
5. Het principe van scheiding van variabelen bij commuterende operatoren.
6. Weten waarom regulariteit van de radiale golffunctie in de oorsprong in het algemeen expliciet geverifieerd moet worden en waarom hier altijd aan is voldaan voor de baangolffuncties binnen een echt atoom.
7. De uitdrukkingen voor de klassieke hamiltoniaan
$$H_0 = \frac{\mathbf{p}^2}{2\mu} + \mathcal{V}(r) \quad \text{and} \quad H_0 = \frac{1}{2\mu}\left(p_r^2 + \frac{\mathbf{L}^2}{r^2}\right) + \mathcal{V}(r) \quad (r \neq 0).$$
8. De uitdrukking voor de kwantummechanische hamiltoniaan
$$\mathcal{H}_0 = -\frac{\hbar^2}{2m_r}\Delta + \mathcal{V}(r).$$
9. De eigenwaardenvergelijkingen voor L_z en $\mathbf{L}^2$ in de Dirac notatie
$$\mathbf{L}^2 |l,m\rangle = l(l+1)\hbar^2 |l,m\rangle$$
$$L_z |l,m\rangle = m\hbar |l,m\rangle$$
en de werking van de *shift operatoren*
$$L_\pm |l,m\rangle = \sqrt{l\,(l+1) - m(m\pm 1)}\,\hbar\,|l, m\pm 1\rangle\,,$$
waar de keuze voor de *positieve* wortel de *Condon en Shortley faseconventie* bepaald.

10. De radiale golfvergelijking

$$\left[\frac{\hbar^2}{2m_r}\left(-\frac{d^2}{dr^2}-\frac{2}{r}\frac{d}{dr}+\frac{l(l+1)}{r^2}\right)+\mathcal{V}(r)\right]R_l(r)=ER_l(r).$$

11. De definitie $\chi_l(r) = rR_l(r)$ en de afleiding van de 1D Schrödinger vergelijking

$$\chi_l'' + \left[\frac{2m_r}{\hbar^2}(E-V)-\frac{l(l+1)}{r^2}\right]\chi_l = 0.$$

2 Hydrogenic atoms

Het tweede hoofdstuk gaat over het oplossen van de Schrödinger vergelijking voor een elektron in het centrale potentiaalveld (Coulombveld) van de kern. Dit wordt het „Bohr atoom" genoemd. De rotatie-toestanden zijn al bekend uit hoofdstuk 1 (bolfuncties). Dus nu moeten we de radiale golfvergelijking oplossen. Je maakt kennis met atomaire eenheden en leert hoe de kwantisatie volgt uit de normeringseis voor de golffunctie. Als uitkomst vind je de discrete energieniveaus van het waterstof atoom (de zgn. waterstof *Termen*) en de bijbehorende golffuncties. Verder leer je het uitrekenen van diagonale en afdiagonale matrix elementen met waterstofgolffuncties.

Thuis bestuderen:

Hoofdstuk 2: Lees de intro. Begrijp wat een één-elektron atoom is en wat er bedoeld wordt met het begrip *waterstofachtig* (*hydrogeen* of *alkali-achtig*). Problems 2.1, 2.2, evenals 2.4 en 2.5 zijn heel nuttig. Problem 2.3 is voor de echte liefhebber van speciale functies; Problem 2.6 is voor diegenen die zich in Mathematica willen bekwamen. Deze opgaven kun je ook gewoon overslaan bij eerste kennismaking.

§ 2.1: Hierin wordt het opstellen van de radiale Schrödinger vergelijking kort samengevat. Neem kennis van de begrippen s golf, p golf, *etc.*, en het gebruik van de naam *orbitaal* voor baangolffunctie. Let op de notatie R_{nl} met als alternatieve schrijfwijzen $R_{10} \equiv R_{1s}$ voor het geval $n, l = 1, 0$.

§ 2.1.1: Het invoeren van *Hartree atomaire eenheden* en het verschijnen van de *fijnestructuurconstante* α. Neem kennis van het verschil tussen de Hartree en Rydberg energie. Maak Problem 2.1.

§ 2.1.2: Bestudeer het limietgedrag van de golffuncties voor $r \to 0$ en $r \to \infty$ en het ontstaan van de *kwantisatieconditie* uit de normeerbaarheidsvoorwaarde voor de golffunctie. Merk op hoe van het *hoofdkwantumgetal*, n, in de theorie verschijnt.

§ 2.2: De *Bohr formule* voor waterstof *niveaustructuur* (*Termdiagram*) en de *Rydberg formule*

$$E_n = -hcR_M \frac{Z^2}{n^2} \quad \Leftrightarrow \quad \frac{1}{\lambda_n} = -R_M \left[\left(\frac{1}{n}\right)^2 - \left(\frac{1}{n_0}\right)^2 \right], \text{ with } n > n_0.$$

Verder de n^2 *ontaarding* van de energie-niveaus en de samenhang met de ontaarding van de rotatiegolffuncties (bolfuncties). Begrijp het verschil tussen essentiële en toevallige ontaarding.

§ 2.3: De algemene uitdrukking voor de waterstofgolffuncties voor de radiale beweging $R_{nl}(\rho)$ en de bijbehorende normeringsfactor $\mathcal{N}$. Bestudeer de figuren voor de radiale golffuncties. Zie de systematiek van het aantal knopen in de golffunctie.

§ 2.3.1: Zorg dat je vertrouwd bent met de representatievrije notatie (Dirac notatie) voor de eigentoestanden van de elektronbaan, $|nlm\rangle$, en de relatie met de golffuncties in de plaatsrepresentatie (met bolcoördinaten).

§ 2.4: Diagonale matrixelementen:

§ 2.4.1: Het uitrekenen van *radiale gemiddelden*. Exacte oplossingen bestaan maar het kan ingewikkeld worden. Neem kennis van Eq. (2.48) maar verspil geen tijd aan het bewijs van Problem 2.3; dat is voor de echte liefhebbers van speciale functies. Je kunt beter je tijd stoppen in Problem 2.2 omdat dit inzicht biedt in de structuur van het Wigner-Eckart theorema.

§ 2.4.2: De *integraal over drie bolfuncties* is de *steen van Rosetta* voor de hoekmiddeling, zie Eq. (2.54) en de rol van $3j$ symbolen. Oefen jezelf in dit soort integralen met Problems 2.4 en 2.5. Een inleiding in $3j$ symbolen komt aan de orde in § 3.4.6 (cf. Appendix J).

§ 2.5: Afdiagonale matrixelementen:

§ 2.5.1: Neem kennis van de *elektrische dipool operator*

$$\mathbf{d} = -\, e\mathbf{r} = -\, ea\rho\,\hat{\mathbf{r}}$$

en het uitrekenen van *koppelingsmatrixelementen = afdiagonale matrixelementen* en het begrip *overgangsdipoolmoment.* Het overgangsdipoolmoment bepaalt de selectieregels voor *optische dipool overgangen.* Deze zijn van groot praktisch belang want zij staan de sterkste interactie van atomen met licht. In de praktijk zijn overgangen toegestaan als het corresponderende $3j$ symbool ongelijk aan nul is.

§ 2.5.2: De eenheidsvector voor richting $\hat{\mathbf{r}}$ en de decompositie naar de sferische basis; hoekmatrixelementen.

§ 2.5.3: Hier geven we uitdrukkingen voor de *overgangsdipool* en definiëren de *overgangssterkte.*

§ 2.5.4: Selectieregels voor optische dipool overgangen; het foton en de spin van het foton. Begrijp het verschil tussen σ_+, σ_- en π overgangen (zie Fig. 2.4). De afleidingen behoren niet tot de tentamenstof.

§ 2.5.5: Bestudeer de bespreking van de Lyman reeks en de Balmer reeks. Merk op dat de som van de overgangswaarschijnlijkheden hetzelfde is voor alle boven (or onder) niveaus van een gegeven manifold (zie Fig. 2.5). Problem 2.6 is een sleutelprobleem, essentieel om later de koppeling van elektronen aan het elektromagnetische veld te begrijpen. Je kunt je vaardigheden met Mathematica oefenen door de integralen uit te rekenen.

Parate kennis:

1. De begrippen *waterstofachtig* (*hydrogeen* of *alkali-achtig*), s golf, p golf, etc..
2. De *atomaire eenheden* van lengte (a) en van energie (Hartree $\hbar^2/m_r a^2$) en waarmee zij corresponderen binnen het atoom.
3. De relatie tussen de *Hartree* en de *Rydberg* atomaire eenheden: $E_H = 2E_R$.
4. De relatie tussen de *Rydberg constante* R_M en de *Rydberg energie*: $E_R = hcR_M$.
5. De relatie tussen de Hartree atomaire eenheid, elektron rustenergie en fijnstructuurconstante:

$$\hbar^2/m_r a^2 = \alpha^2 m_r c.$$

6. De niveausplitsing van de *hoofdstructuur is typisch* een factor α^2 kleiner dan de energie van de *rustmassa* van het elektron. Het Bohr/Schrödinger atoom kan als een zwakrelativistisch systeem beschouwd worden.
7. De energieniveaus (*Termen*) van hydrogene atomen en het begrip *Termdiagram*,

$$E = -(\alpha^2 m_r c^2) Z^2/2n^2,$$

en verder de *Rydberg formule*

$$\lambda_n^{-1} = -R_M \left[(1/n)^2 - (1/n_0)^2 \right] \quad \Leftrightarrow \quad \Delta E_n = E_n - E_{n_0} = hc/\lambda_n, \text{ with } n > n_0.$$

8. De afleiding van de relatie voor *radiale gemiddelden*

$$\langle \rho^k \rangle \equiv \langle nlm|\rho^k|nlm\rangle = \int \rho^{k+2}\tilde{R}^2_{nl}(\rho)d\rho,$$

   waar

$$\int \tilde{R}^2_{nl}(\rho)\rho^2 d\rho = 1.$$

9. De definitie van de *electrische-dipool operator*,

$$\mathbf{d} = -\,e\mathbf{r} = -\,ea\rho\,\hat{\mathbf{r}}.$$

10. Weten wanneer $3j$ symbolen nul zijn of 1 en zorg dat je $3j$ symbool regels kunt toepassen (de driehoeksongelijkheid, de $3m$ som regel, de m inversie regel, en de permutatie regels). Zie ook de bespreking van de $3j$ symbolen in § 3.2.2 en Appendix J.

3 Angular momentum

We beginnen het derde hoofdstuk met een verrassing: na alle arbeid in Hoofdstuk 1 blijkt dat we de eigenwaarden van $\mathbf{L}^2$ en L_z en de eigenschappen van L_+ en L_- ook kunnen verkrijgen *zonder* de Schrödinger vergelijking op te lossen. Het enige wat daarvoor nodig blijkt zijn de commutatie relaties voor L_x, L_y en L_z. Uitgaande van deze relaties leiden we een algebra af waarmee we de eigenschappen van het baanimpulsmoment kunnen reproduceren. Hiervoor gebruiken we de representatie-vrije notatie van Dirac (een notatie zonder „golffuncties”). Vervolgens generaliseren we deze aanpak. Dat kan omdat *iedere* observabele die voldoet aan eenzelfde stel commutatie relaties als L_x, L_y en L_z aan dezelfde algebra moet voldoen. Dit noemen we de algebra van gekwantiseerd impulsmoment. Nu blijkt dat binnen deze algebra ook halfgehele kwantumgetallen mogelijk zijn (de elektron spin, $s = 1/2$, is daarvan een bekend voorbeeld). Van cruciaal belang voor een goed begrip van de gehele cursus is het optellen van impulsmomenten. We maken kennis met de *gekoppelde* en de *ongekoppelde* representatie en de *Clebsch-Gordan transformatie* tussen deze representaties. Het vector-koppelingsmodel is daarbij een belangrijk hulpmiddel, i.h.b. voor het lezen van $3j$ symbolen.

In het tweede deel van het hoofdstuk zoeken we uit hoe de impulsmoment *operatoren* en de impulsmoment *toestanden* transformeren onder een verandering van kwantisatieas. Dit wordt representatie theorie genoemd. Het blijkt dat we de impulsmoment operatoren kunnen opvatten als operatoren waarmee we het fysische systeem een klein stukje (infinitesimaal) draaien.

Thuis bestuderen:

Let op, aan Hoofdstuk 3 moet je je niet vertillen. De stof is belangrijk omdat gekwantiseerd impulsmoment een sleutelrol speelt in de kwantum fysica en zeker in de Atoomfysica. Het is essentieel voor een goed begrip van optisch overgangen in atomen. Het hoofdstuk biedt veel extra stof voor studenten met een theoretische belangstelling. De volgende stof is deel van de cursus, de facultatieve stof wordt daarna samengevat:

§ 3.1: Dit is een zeer belangrijke paragraaf. Het blijkt dat alle eigenschappen van impulsmoment volgen uit een *algebra* die afgeleid wordt uit de *commutatierelaties* voor J_x, J_y en J_z. De liefhebbers kunnen de afleiding bestuderen. Voor *allen* is de samenvatting (3.1.0.1) belangrijk. De belangrijkste conclusie is dat naast heeltallige impulsmomenten $j = 0, 1, 2, \cdots$ ook halftallige impulsmomenten, $j = \frac{1}{2},\ \frac{3}{2},\ \frac{5}{2}, \cdots$, mogelijk zijn. Voor de laatste klasse zal in § 3.9.3 blijken dat ze geen *geen klassiek analogon* hebben.

> § 3.1.1: Hier bespreken we de decompositie van de impulsmoment vector $\mathbf{J}$ in de *cartesische basis* en de *sferische basis* en het subtiele verschil tussen de *standaard componenten* J_0, J_{+1} en J_{-1} en de *shift operatoren* J_z, J_+ en J_-.

§ 3.2: Uitgaande van de eigenwaarden kun je matrix representaties construeren die voldoen aan alle in § 3.1 genoemde eigenschappen. Ga na hoe dit gaat in de sferische en cartesische basis voor $l = 1$. Ga ook na hoe de Pauli matrices volgen voor $s = 1/2$. Problem 3.1 is facultatief.

§ 3.3: In het algemene deel van deze sectie wordt het verschil tussen impulsmoment in de klassieke mechanica en de kwantummechanica samengevat. Zorg dat je het begrip *polarisatie* goed begrijpt en inziet dat de polarisatie in de kwantummechanica de plaats inneemt van de impulsmoment vector uit de klassieke mechanica. Het *vector model* van Fig. 3.1 helpt je bij het voorstellen van enerzijds de grootheid $\mathbf{J}$ (die niet waarneembaar is) en anderzijds de projecties daarvan op de kwantisatieas (die wel waarneembaar zijn). Maak Problem 3.2.

> § 3.3.1: In deze paragraaf bespreken hoe de polarisatie gemeten kan worden. Begrijp wat er bedoeld wordt met een *zuiver* ensemble, een *random* ensemble en met de *polarisatiegraad.* Verder bespreken we hoe de polarisatie bepaald kan worden met de dichtheidsmatrix.

- § 3.3.2: In deze paragraaf berekenen we de polarisatie voor een $s = 1/2$ systeem, ook wel qubit genoemd, en laten zien dat je de polarisatie van een willekeurige toestand meetkundig kunt weergeven als een punt op de *Bloch bol.* Dit is een mooi stukje kwantummechanica dat een belangrijke rol speelt in de moderne atoomfysica en bij kwantum informatieverwerking. Zorg dus dat je de Bloch bol goed begrijpt; dat je begrijpt dat de polarisatievector een vector in de 3D reële ruimte is maar dat de Hilbertruimte van het qubit een 2D complexe vector ruimte is die af te beelden is op het *oppervlak van de bol.* Verwar dus niet een vector in het lab met een toestand van het qubit.
- § 3.3.3: Een alternatieve aanpak om spin systemen te beschrijven is het dichtheidsmatrix formalisme (cf. Appendix F.3). Naast het beschrijven van zuivere toestanden kun je met dit formalisme ook de statistische mengsels aanpakken. Begrijp hoe je de polarisatie voor een zuiver ensemble uitrekent met de dichtheidsoperator en welke vorm de dichtheidsoperator aanneemt in de matrix representatie. Ga door deze sectie en overtuig jezelf van Eq. (3.74).

§ 3.4: De volgende subsecties zijn *onmisbaar voor een goed begrip van de hele stof.*

- § 3.4.1: Allereerst introduceren we de Hilbert ruimte voor een systeem met twee impulsmomenten, $\boldsymbol{j}_1$ en $\boldsymbol{j}_2$. We definiëren de *ongekoppelde basis* als de basis gevormd door het tensorproduct van de bases voor de individuele impulsmomenten. Hierbij moeten we opletten want het tensorproduct is een geordend product. Hieraan wordt doorgaans weinig aandacht besteed omdat dit geen opvallende consequenties heeft zolang we ons beperken tot twee impulsmomenten. Bij koppeling van meer dan twee impulsmomenten ligt dat anders. Daarop wordt in detail teruggekomen in Section 3.5. De details kun je vergeten maar begrijp wel het verschil tussen een *gestrekte* en een *niet gestrekte* toestand (zie Example 3.1 en 3.4.2).
- § 3.4.2: Hier leren we hoe twee impulsmoment operatoren opgeteld moeten worden (met de *driehoeksongelijkheid* in ons achterhoofd). Dit zal herhaaldelijk terugkomen in de komende hoofdstukken. Begrijp het verschil tussen de gekoppelde en de ongekoppelde representatie (maak Problem 3.3). Overtuig jezelf dat ze dezelfde dimensie hebben (zie Problem 3.4) omdat ze dezelfde Hilbertruimte opspannen. Bestudeer zorgvuldig het zgn. *vectorkoppelingsmodel* zoals geschetst in Fig. 3.4. Het begrip gestrekte toestand komt op vele plaatsen in de stof terug. Zorg er dus voor dat je goed begrijpt wat hiermee bedoeld wordt.

- § 3.4.6: Hier leren we de zogenaamde *Clebsch-Gordan transformaties* tussen de gekoppelde en de ongekoppelde representatie. Begrijp dat deze transformaties eenvoudig volgen uit de volledigheidsrelaties. De gekoppelde en de ongekoppelde representatie zijn verbonden door een unitaire transformatie - zie Problem 3.10.

§ 3.6: In deze sectie introduceren we *koppeling van impulsmomenten.* De vorm van de koppeling is belangrijk maar bedenk dat de gekoppelde en ongekoppelde basis goed gedefinieerd zijn ook onafhankelijk van de aanwezigheid van een koppelingsmechanisme. Als $\boldsymbol{j}_1$ en $\boldsymbol{j}_2$ behouden grootheden zijn zal ook hun vector som, $\mathbf{J} = \boldsymbol{j}_1 + \boldsymbol{j}_2$, een behouden grootheid zijn. Daarin komt verandering zodra $\boldsymbol{j}_1$ en $\boldsymbol{j}_2$ ergens aan gekoppeld worden (bijvoorbeeld aan elkaar). We maken onderscheid tussen *interne* en *externe* koppeling. In beide gevallen zijn $\boldsymbol{j}_1$ en $\boldsymbol{j}_2$ niet langer behouden. Bij *interne* koppeling blijft $\mathbf{J}$ behouden omdat het systeem mechanisch gesloten blijft. Bij externe koppeling is ook $\mathbf{J}$ niet langer behouden. In belangrijke gevallen is er zowel een interne als een externe koppeling actief. Begrijp wat er in dat geval bedoeld wordt met *koppeling van de J niveaus* - zie ook Section 3.4.5. De inproductregels moet je vlot kunnen toepassen. Die worden overal in de syllabus toegepast (maak Problem 3.18).

§ 3.7: Lees deze sectie door en zorg dat je bekend bent met het begrip $6j$ symbool en dat deze gedefinieerd zijn middels $3j$ symbolen.

§ 3.8: Hier begint de bespreking van de representatie theorie. Dat is de theorie die ons leert wat er in de Hilbertruimte gebeurt als we een fysisch systeem in de reële ruimte roteren. Het is een interessante maar ook lastige sectie.

§ 3.8.1: We gaan in detail na hoe de operatoren en de toestanden van een $s = 1/2$ systeem transformeren onder een zuivere rotatie van of rond de kwantisatieas. Begrijp wat we bedoelen met een *zuivere* rotatie.

§ 3.8.2: Het blijkt dat we een willekeurige zuivere draaiing kunnen beschrijven met drie draaihoeken, de *Eulerse hoeken* α, β, en γ. Eerst doen we dat in een meedraaiend assenstelsel (zoals een piloot dat ervaart in de cockpit van een vliegtuig). Fig. 3.7-b is daarbij heel belangrijk. Daarna laten we zien dat we dezelfde draaiing ook kunnen realiseren met opeenvolgende draaiingen in een vast coördinatenstelsel (het laboratorium stelsel) rond de z as, de y as en weer de z over *dezelfde* Eulerse hoeken (maar in *omgekeerde* volgorde). We schrijven de draaioperatoren in de reële ruimte als 3×3 matrices. Je hoeft de afleiding niet te kunnen reproduceren maar je moet wel de Eulerse hoeken kunnen definiëren aan de hand van Eqs. (3.183) en (3.187).

§ 3.8.3: Nu bespreken we de unitaire transformaties in de Hilbert ruimte die corresponderen met dezelfde Euler rotaties. Merk op dat de transformaties nu met een 2×2 matrix worden beschreven. Dat komt omdat we ons hier beperken tot een tweeniveausysteem (NB. voor de rotatie van quarks wordt het een 3×3 matrix). Problem 3.10 behandelt een belangrijk resultaat en is een goede oefening om je kennis van complexe 2×2 matrices op te frissen. Merk op dat niet één maar twee unitaire transformaties corresponderen met een rotatie in de reële ruimte. Dit heeft geen gevolg voor de operatoren (die transformeren als klassieke heeltallige impulsmoment operatoren) maar de toestanden worden tweewaardige complexe functies.

§ 3.8.4: Na al het voorwerk zijn we nu in staat om een relatie neer te schrijven tussen de $s = 1/2$ impulsmoment operatoren en draaiingen in het laboratorium. Met Eq. (3.210) komen we tot de fundamentele conclusie dat de spin operator S_z equivalent is met de operator voor een infinitesimale rotatie rond de z as (zie Problem 3.20 voor het formele bewijs). Problem 3.18 gaat over het algemene geval (i.e., rotatie rond een willekeurige as) en is voor de liefhebbers.

§ 3.8.5: In deze sectie laten we zien dat de relaties die we in de vorige secties afgeleid hebben voor $s = 1/2$ gegeneraliseerd kunnen worden tot uitdrukkingen geldig voor spins van willekeurige grootte. Dit resultaat vormt de basis voor de formele definitie van impulsmoment in§ 3.9.1.

§ 3.9.3: Hier bereiken we een *mijlpaal uit de natuurkunde*. We komen tot de conclusie dat een fysisch systeem met halftallige spin gedraaid worden over een hoek van 4π om de oorspronkelijke golffunctie terug te krijgen (i.p.v. 2π, zoals bij de bolfuncties en zoals verwacht op basis van de klassieke natuurkunde). We zeggen dat halfgeheel impulsmoment *geen klassiek analogon* heeft. Lees deze subsectie door en zorg dat je bekend bent met het gebrek aan klassieke analogon.

§ 3.11: In deze paragraaf demonstreren we dat we de transformatiematrices van § 3.9.4 kunnen genereren met de systematische methode van § 3.9.1.

§ 3.11.1 Voor een $s = 1/2$ systeem

§ 3.11.2 Voor een $s = 1$ systeem.

Parate kennis:

1. De commutatie relaties voor een algemeen impulsmoment **J**,
$$[J_x, J_y] = i\hbar J_z,\ [J_y, J_z] = i\hbar J_x \text{ and } [J_z, J_x] = i\hbar J_y.$$
De eigenwaarde vergelijkingen,
$$\begin{aligned}\mathbf{J}^2 \left|j, m\right\rangle &= j(j+1)\hbar^2 \left|j, m\right\rangle \\ J_z \left|j, m\right\rangle &= m\hbar \left|j, m\right\rangle ,\end{aligned}$$
De kwantumgetallen j en m staan bekend onder de naam *rotatie-kwantumgetallen*; voor gegeven **J** zijn deze beiden *geheel* or *halfgeheel.* Het kwantumgetal m is het *magnetisch kwantumgetal* met waarden beperkt tot het interval $-j \le m \le j$. De werking van de *ladder operatoren*
$$J_\pm \left|j, m\right\rangle = \sqrt{j\,(j+1) - m(m\pm 1)}\,\hbar \left|j, m \pm 1\right\rangle ,$$
waar de keuze voor het positieve teken vóór de wortel bekend staat als de *Condon en Shortley fase conventie*.
2. Zorg dat je vanuit de eigenwaardenvergelijkingen de *matrix representatie* kunt genereren.
3. De definitie van *polarisatie van impulsmoment*: $\mathbf{P} = (\langle J_x/j\hbar\rangle, \langle J_y/j\hbar\rangle, \langle J_z/j\hbar\rangle)$.
4. De relaties $R(\alpha,\beta,\gamma) = R_{z''}(\gamma)R_{y'}(\beta)R_z(\alpha)$ en $R(\alpha,\beta,\gamma) = R_z(\alpha)R_y(\beta)R_z(\gamma)$ en de definitie van de Eulerse hoeken (Fig. 3.7-b).
5. Weet dat je een willekeurige $s = 1/2$ toestand kunt schrijven als $\left|\chi\right\rangle = \cos\theta/2\ \left|\uparrow\right\rangle + e^{i\phi}\sin\theta/2\ \left|\downarrow\right\rangle$ en dat je daarmee de afbeelding op de Bloch bol kunt uitwerken.
6. Zorg dat je de inproductregels kent:
$$\begin{aligned}\mathbf{L}\cdot\mathbf{S} &= L_xS_x + L_yS_y + L_zS_z \\ \mathbf{L}\cdot\mathbf{S} &= L_zS_z + \tfrac{1}{2}\left(L_+S_- + L_-S_+\right) \\ \mathbf{L}\cdot\mathbf{S} &= \tfrac{1}{2}(\mathbf{J}^2 - \mathbf{L}^2 - \mathbf{S}^2).\end{aligned}$$
7. Zorg dat je de vector optelling $\mathbf{J} = \boldsymbol{j}_1 + \boldsymbol{j}_2$ kunt uitvoeren in een vector diagram en ken de driehoeksongelijkheid
$$|j_1 - j_2| \le J \le j_1 + j_2.$$
8. Zorg dat je de *Clebsch-Gordan decompositie* kunt neerschrijven „in beide richtingen” door gebruik te maken van de volledigheidsrelatie
$$\begin{aligned}\left|JM\right\rangle &= \sum_{m_1=-j_1}^{j_1}\sum_{m_2=-j_2}^{j_2} \left|j_1m_1; j_2m_2\right\rangle\langle j_1m_1; j_2m_2\left|JM\right\rangle \\ \left|j_1m_1; j_2m_2\right\rangle &= \sum_{J=|j_1-j_2|}^{j_1+j_2}\sum_{M=-J}^{J} \left|JM\right\rangle\left\langle JM\right|j_1m_1; j_2m_2\rangle .\end{aligned}$$
9. Weet dat de Clebsch-Gordan coëfficiënten kunnen worden herschreven in de vorm van *Wigner 3j symbolen*, waarvoor een handig *grafisch model* bestaat. Alle *symmetrieregels* zoals gegeven in Appendix J.1 moet je uit het hoofd kunnen opschrijven.

3 Angular momentum, facultatieve stof

§ 3.4.3: Hier geven we een aantal commutatie relaties voor $\boldsymbol{j}_1$ en $\boldsymbol{j}_2$ met $\mathbf{J}$. Dit soort commutatierelaties kun je afleiden als je ze nodig hebt. Ga ze dus niet uit je hoofd leren maar ga na of het afleiden lukt.

§ 3.4.4: Hier staan drie belangrijke selectieregels voor het uitrekenen van j_{1z}, j_{2z}, $j_{1\pm}$, $j_{2\pm}$, in de basis van $\mathbf{J}$. Overtuig jezelf dat deze relaties intuïtief correct zijn. De afleiding vind je in Problems 3.7-3.9.

§ 3.4.5: Als we de matrix elementen van j_{1z}, j_{2z}, $j_{1\pm}$, $j_{2\pm}$ in de basis van $\mathbf{J}$ willen uitrekenen blijkt er een nieuwe fase conventie nodig. Je hoeft niet te begrijpen hoe dat precies werkt maar het is wel goed om kennis te nemen van de nieuwe conventie Eq. (3.99): *Voor $J' \neq J$ de matrixelementen van j_{1z} worden gekozen als reëel en niet negatief*, $\langle J', M|j_{1z}|J, M\rangle \geq 0$. Deze conventie impliceert - zie Eqs. (3.103) en (3.105) en lees de samenvatting aan het eind van de sectie: $\langle J-1, M+1|j_{1+}|J, M\rangle \geq 0$ en $\langle J+1, M+1|j_{1+}|J, M\rangle \leq 0$.

§ 3.4.7: De recursierelaties worden gebruikt om de CGCs uit te rekenen. Dat is natuurlijk heel belangrijk maar niet voor ons want dat is deel van Mathematica.

§ 3.5: In deze sectie onderzoeken we de symmetrieregels van de Clebsch-Gordan coëfficiënten (CGCs). Deze zijn lastig om te onthouden, daarom heeft Wigner de CGCs getransformeerd naar $3j$ symbolen. Die hebben eenvoudige symmetrierelaties en met de driehoeksongelijkheid kunnen we snel te zien of zij nul zijn of niet - Fig. 3.4. In het laatste geval moeten we de waarde opzoeken in Appendix J (of uitrekenen met Mathematica). Voor de liefhebbers worden de rekenregels met $3j$ symbolen afgeleid maar dat behoort niet tot de tentamenstof. Je hoeft de regels dus niet te kunnen afleiden *maar je moet ze wel kunnen toepassen.* De symmetrierelaties staan in Appendix J.1 en als je verstandig bent leer je ze nu meteen uit je hoofd, daar kun je veel plezier van hebben.

§ 3.5.1: Hier bespreken we de koppelingsvolgorde en leiden we de symmetrierelaties af voor de Clebsch-Gordan coëfficiënten.

§ 3.5.1.1: De verwisselingssymmetrie is bijzonder voor twee identieke impulsmomenten. We laten zien dat de paartoestanden symmetrisch zijn voor heeltallige impulsmomenten en antisymmetrisch voor halftallige impulsmomenten. Dit heeft natuurlijk gevolgen voor de relatie tussen spin en kwantumstatistiek.

§ 3.5.2: We hebben het optellen van impulsmomenten besproken maar kunnen we ze ook van elkaar aftrekken? Voor klassieke vectoren is dat evident. Dat kan door het omdraaien van de vectorpijl zoals geschetst in Fig. 3.3. Dit principe werkt bij heeltallige impulsmomenten maar bij halftallige impulsmomenten klopt dit niet. Bij het vergelijken van de CGCs van de twee situaties blijkt er een fasesprong van $(-1)^{2j_2}$ op te treden waarbij $\boldsymbol{j}_2$ het impulsmoment is dat geïnverteerd wordt - zie Fig. 3.3. Dit heeft alleen consequenties voor een halftallig impulsmoment.

§ 3.5.3: In deze sectie introduceren we de transformatie van CGC naar $3j$ symbool. De beperkte symmetrie van de CGCs is het gevolg van het inproduct dat zowel een ket deel als een bra deel heeft. Na hermitisch conjugeren van het bra deel krijgen we een tensorproduct van 3 kets dat een scalar moet opleveren omdat de drie vectoren moeten optellen tot nul, $\boldsymbol{j}_1 + \boldsymbol{j}_2 + \mathbf{J} = 0$. Die scalar is het $3j$ symbool.

§ 3.5.3.1: Belangrijk: hier staan de symmetrierelaties samengevat - zie ook Appendix J.1. Leer ze uit je hoofd. Dat zeggen we niet snel maar hierbij zijn hele grote collega's je voorgegaan...

§ 3.5.3.2: Hier worden de faseregels voor $3j$symbolen afgeleid.

§ 3.5.3.3: Oefen met het vector model voor $3j$ symbolen - zie Fig. 3.4

§ 3.7: We gaan nu een stap verder: we gaan drie impulsmomenten met elkaar koppelen. Het totaal impulsmoment wordt dan $\mathbf{J} = \boldsymbol{j}_1 + \boldsymbol{j}_2 + \boldsymbol{j}_3$. De volgorde van koppeling komt nu prominent naar voren omdat er meerdere manieren zijn om dit te doen. We introduceren herkoppelingscoëfficiënten om twee manieren van koppeling met elkaar te vergelijken middels een inproduct, e.g. $\langle (j_{12}j_3)JM|(j_1j_{23})J'M'\rangle$. Zorgvuldig gebruik makend van de koppelingsregels kunnen we deze coëfficiënten uitdrukken in een som van producten van *vier* $3j$ symbolen - zie Eq. (3.166) en Appendix J.2.

§ 3.7.1: Bij het koppelen van 3 impulsmomenten (j_1, j_2, j_3) moeten we rekening houden met 6 impulsmomenten $(j_1, j_2, j_3, j_{12}, j_{13}, j_{23})$. Bij het koppelen van twee impulsmomenten (j_1, j_2) waren dat er slechts drie (j_1, j_2, j_{12}). Dat laatste geval konden we visualiseren met de *driehoek* van het vectormodel. Bij 6 impulsmomenten is dit mogelijk met een *tetraëder* - zie Fig. 3.6. Gebruik makend van de symmetrie van de tetraëder heeft Wigner het $6j$ symbool ontworpen. Dat is weer een scalar omdat we eisen dat $\boldsymbol{j}_1 + \boldsymbol{j}_2 + \boldsymbol{j}_2 + \mathbf{J} = 0$. De algemene relatie voor het $6j$ symbool wordt afgeleid in Problem 3.19. De afleidingen kun je overslaan maar kijk even goed naar de symmetrieregels van de $6j$ symbolen samengevat in § 3.7.1.1 en Appendix J.2.

§ 3.9: (*facultatief maar als je vertrouwd bent met de Euler rotaties kun je best proberen om tot § 3.9.4 te komen*) Hier beginnen we met een schone lei omdat impulsmoment op een meer fundamentele wijze gedefinieerd kan worden als een infinitesimale draaiing.

§ 3.9.1 We beginnen met de formele definitie van de impulsmoment operator als een *infinitesimale rotatie.*

§ 3.9.2: We generaliseren de nieuwe definitie voor het geval van *willekeurige* vormen van impulsmoment. We laten zien dat uit deze definitie de commutatierelaties volgen en daarmee alles wat we in § 3.4 hebben geleerd over impulsmoment.

§ 3.9.3: Hier bereiken we een *mijlpaal uit de natuurkunde.* We komen tot de conclusie dat een fysisch systeem met halftallige spin gedraaid worden over een hoek van 4π om de oorspronkelijke golffunctie terug te krijgen (i.p.v. 2π, zoals bij de bolfuncties en zoals verwacht op basis van de klassieke natuurkunde). We zeggen dat halfgeheel impulsmoment *geen klassiek analogon* heeft.

§ 3.9.4: Hier bespreken de unitaire transformaties in de Hilbert ruimte die corresponderen met Euler rotaties α, β, γ voor het algemene geval (willekeurig impulsmoment). Hierbij maken we kennis met de draaimatrices van Wigner, $\mathscr{D}^j_{m'm}(\alpha, \beta, \gamma)$.

§ 3.9.5: Uitgaande van de Clebsch-Gordan decompositie kunnen we de transformatie eigenschappen van sferische tensor operatoren afleiden. We demonstreren dit voor de sferische tensor operatoren $\mathbf{T}^{(0)}$ (rang 0), $\mathbf{T}^{(1)}$ (rang 1) en $\mathbf{T}^{(2)}$ (rang 2).

§ 3.10: In deze sectie maken we de stap van vectoroperatoren naar tensoroperatoren van willekeurige orde. Dat is de laatste stap van generalisatie. Binnen de syllabus is het alleen belangrijk voor het hoofdstuk over de elektrische hyperfijnstructuur en dat is niet deel van het examen. Een bijzonder detail is dat de methoden van deze sectie het mogelijk maken om als een speciaal geval de *Gaunt* integraal op te lossen. - zie Problem 3.24.

4 Fine structure of hydrogen-like atoms - deel 1

In zekere zin komen we nu pas toe aan het echte werk. We laten de wereld van exacte oplossingen achter ons en gaan verder met *storingsrekening.* We richten ons eerst op de *fijnstructuur* en in Hoofdstuk 5 op de *hyperfijnstructuur* van waterstofachtige atomen. De term *fijnstructuur* verwijst naar kleine afwijkingen van de hoofdstructuur die het gevolg zijn van „storingen” als gevolg van eigenschappen van het *elektron.* De *hyperfijnstructuur* wordt bepaald door eigenschappen van de *kern.* We beginnen het *vierde* college met de fijnstructuur van waterstofachtige atomen, gebruik makend van storingsrekening. Eerst berekenen we een *relativistische correctie.* Die bestaat uit twee bijdragen, een correctie van de kinetische energie (*massacorrectie*) en een correctie van de potentiële energie (*Darwin correctie*). Daarna leren we hoe het elektron binnen het atoom een Lorentzkracht ervaart als we een extern magneetveld aanleggen (waardoor de rotatiesymmetrie wordt gebroken). Dit is de oorsprong van het *baanmagnetisme* (*baan-Zeemaninteractie* en *Larmor precessie*) en van het *diamagnetisme.* Dan postuleren we de *elektron spin* (ook een relativistisch fenomeen) en de *spin-Zeemaninteractie.* Al deze bijdragen worden tenslotte gereduceerd tot een effectieve hamiltoniaan voor de wisselwerking van het elektron met een extern magneetveld: de *Zeeman hamiltoniaan voor het elektron.* Dit is het werkpaard van de elementaire atoomfysica. Alle genoemde interacties kunnen berekend worden met gewone eerste orde storingsrekening.

Thuis bestuderen:

Hoofdstuk 4 - deel 1: De begrippen *relativistische massacorrectie, Darwin correctie, Zitterbewegung en Compton golflengte* λ_C*, Lorentzkracht* $\mathbf{F}$, *gegeneraliseerde potentiële energie* $V(\mathbf{r},\mathbf{v},t)$, *vectorpotentiaal* $\mathbf{A}(\mathbf{r})$, *scalar potentiaal* $\varphi(\mathbf{r})$, *kinetisch impuls* $m\mathbf{v}$, *elektromagnetisch impuls* $q\mathbf{A}$, *canoniek impuls* $\mathbf{p}$, *hamiltoniaan* H, *lagrangiaan* L, *kinetische energie* T, *diamagnetisch moment* $\boldsymbol{\mu}_{dia}$ en *magnetische polariseerbaarheid* α_M, *baanmagnetisch moment* $\boldsymbol{\mu}_L$, *spinmagnetisch moment* $\boldsymbol{\mu}_S$, *Bohr magneton*, *Larmor precessie*, *Stern-Gerlach methode.* Lees de introductie. Realiseer je de sleutelrol van waterstof voor de ontwikkeling van de moderne natuurkunde.

§ 4.1: Relativistische en stralingsverschuivingen:

- § 4.1.1: Het afleiden van de *relativistische massacorrectie* H_r^{mass} uitgaande van de relativistische hamiltoniaan. Dit is de correctieterm voor de kinetische energie van het elektron (zie Fig. 4.1).
- § 4.1.2: De *Darwincorrectie* H_r^{Darwin} is de correctieterm voor de potentiële energie van het elektron (zie Fig. 4.1). De oorsprong van deze correctie kun je enigszins visualiseren als een soort „uitsmeren” van de ladingsverdeling van het elektron over een *Compton golflengte* λ_C als gevolg van de *Zitterbewegung* van relativistische elektronen. Hierdoor wordt de bindingsenergie kleiner voor elektronen die dicht bij de kern komen (s elektronen). Begrijp wat deze correctie gemeen heeft met de Lamb shift en de nucleaire volume verschuiving (als gevolg van de ladingsverdeling in de kern) - zie Problem 4.1.
- § 4.1.3: De *Lamb shift* is ongelofelijk belangrijk maar past helaas niet binnen dit college (zie Fig. 4.1). De oorsprong kun je ook enigszins visualiseren als een „uitsmeren” van de ladingsverdeling over een afstand veel kleiner dan λ_C maar veel groter dan de r_p, de straal van de *ladingverdeling van het proton*, als gevolg van de *nulpuntsoscillaties van het elektromagnetische veld.* Dit heuristische model staat bekend als *Welton's* beeld van de Lamb shift.

§ 4.2: Fris je kennis op van de klassieke mechanica (Appendix C): de relatie $H = \mathbf{p}\cdot\mathbf{v} - L$ tussen de Hamiltoniaan en de Lagrangiaan $L = T - V$ en de afleiding van de hamiltoniaan voor een elektron in een klassiek elektromagnetisch veld

$$\mathcal{H} = \frac{1}{2m}(-i\hbar\boldsymbol{\nabla} - q\mathbf{A})^2 + q\varphi\left(r\right).$$

Bestudeer zorgvuldig de afleiding van de effectieve hamiltoniaan voor een atoom in een magnetisch veld $\mathbf{B}(\mathbf{r})$

$$\mathcal{H} = \mathcal{H}_0 - \frac{q}{2m}\mathbf{L}\cdot\mathbf{B}(\mathbf{r}) + \frac{q^2}{8m}r_\perp^2\mathbf{B}^2(\mathbf{r}),$$

gebruik makend van de Coulomb ijking, $\boldsymbol{\nabla}\cdot\mathbf{A} = 0$, en de uitdrukking voor de vectorpotentiaal voor een homogeen magnetisch veld, $\mathbf{A} = \frac{1}{2}\mathbf{B}\times\mathbf{r}$. Problem 4.2 is facultatief maar super geschikt om je kennis van de klassieke mechanica op te frissen.

§ 4.3: Waterstofachtige atomen in een extern magneetveld:

- § 4.3.1: Bestudeer goed hoe een *magnetisch moment* aangetoond kan worden met de *Stern-Gerlach methode* (zie Fig. 4.3). Begrijp het verschil tussen een *permanent* en een *geïnduceerd* moment evenals het begrip *magnetische polariseerbaarheid.* Let op de tekenconventies bij uitdrukkingen voor het magnetisch moment $\boldsymbol{\mu}_L = \gamma_L\mathbf{L} = -g_L\mu_B\,(\mathbf{L}/\hbar)$; realiseer je dat voor het elektron de gyromagnetische verhouding γ_L *negatief* is maar de g_L factor (per definitie) *positief.*
- § 4.3.2: Bestudeer de begrippen *diamagnetisme*, *diamagnetische susceptibiliteit* en *magnetisatie.*
- § 4.3.3: Begrijp de verschillen tussen de begrippen *baanmagnetisch moment vector operator* $\boldsymbol{\mu}_L$, *„het” baanmagnetisch moment* μ_L, *effectief baanmagnetisch moment* μ_{eff} en grootte (magnitude) *van het baanmagnetisch moment* $\sqrt{\langle\boldsymbol{\mu}_L\cdot\boldsymbol{\mu}_L\rangle}$. De zeeman hamiltoniaan voor de baanbeweging is $\mathcal{H}_Z = -\boldsymbol{\mu}_L\cdot\mathbf{B}$. Begrijp de Fig. 4.4$a/b$.
- § 4.3.4: Het koppel op het impulsmoment, $d\mathbf{L}(t)/dt = \boldsymbol{\mu}_L\times\mathbf{B}$ geeft aanleiding tot *Larmor precessie* van $\boldsymbol{\mu}_L$ om de veldrichting $\omega_L = g_L(e/2m_e)B$. Berekenen van niveausplitsing met eerste orde storingsrekening (baan Zeeman effect). Begrijp de Fig. 4.4c.
- § 4.3.5: Hier wordt *spin gepostuleerd*, begrijp waarom spin *iets totaal anders* is dan impulsmoment van een klassiek klopje ronddraaiende lading.
- § 4.3.6: Maak jezelf vertrouwd met de begrippen *elektron spin, g factor, gyromagnetische verhouding, elektron anomalie*, *intrinsieke magnetisch moment* en *spin-Zeeman effect.* Let op de tekenconventies bij uitdrukkingen voor het magnetisch moment $\boldsymbol{\mu}_s = \gamma_e\mathbf{S} = -g_e\mu_B\,(\mathbf{S}/\hbar)$; realiseer je dat (net als bij $\boldsymbol{\mu}_L$) de gyromagnetische verhouding γ_e *negatief* is maar de g_e factor (per definitie) *positief.* Verder is de hamiltoniaan van het type $\mathcal{H}_Z = -\boldsymbol{\mu}_s\cdot\mathbf{B}$ en het koppel wordt beschreven met $d\mathbf{S}(t)/dt = \boldsymbol{\mu}_L\times\mathbf{B}$.
- § 4.3.7: Hier vind je de totale Zeeman hamiltoniaan voor het elektron.

Parate kennis:

1. De relativistische en radiatieve energie verschuivingen: de relativistische massa correctie, Darwin term en Lamb shift, hun oorsprong en relatie met impulsmoment.
2. De *Zeeman Hamiltoniaan* voor het elektron

$$\mathcal{H}_Z = -(\boldsymbol{\mu}_S + \boldsymbol{\mu}_L)\cdot\mathbf{B} - \tfrac{1}{2}\boldsymbol{\mu}_{dia}\cdot\mathbf{B}.$$

3. De definities van de *magnetische momenten*, van het *Bohr magneton* μ_B en de *magnetische polariseerbaarheid* α_M:

$$\left.\begin{array}{ll}\boldsymbol{\mu}_L = \gamma_L\mathbf{L} = -g_L\mu_B\,(\mathbf{L}/\hbar) & g_L \simeq 1\\ \boldsymbol{\mu}_S = \gamma_e\mathbf{S} = -g_e\mu_B\,(\mathbf{S}/\hbar) & g_e \simeq 2\end{array}\right\}\ \mu_B = (e\hbar/2m_e)$$

$$\boldsymbol{\mu}_{dia} = -\alpha_M\mathbf{B} \qquad\qquad \alpha_M \simeq (e^2/4m_e)\langle r_\perp^2\rangle.$$

4. De energiesplitsing van de *fijnstructuur* is typisch een factor α^2 kleiner dan de energiesplitsing van de *hoofdstructuur*.

4 Fine structure of hydrogen-like atoms - deel 2

Het „Zeeman" magneetveld kan nooit helemaal uitgezet worden omdat een *bewegend* elektron in een elektrisch veld altijd een (bewegingsgeïnduceerd) magneetveld ervaart in de richting van het impulsmoment **L**. De elektron spin **S** koppelt aan dit *interne veld*, een fenomeen dat bekend staat als *spin-baan koppeling.* Bij afwezigheid van een extern veld koppelen daarom spin **S** en baan **L** tot een totaalimpulsmoment $\mathbf{J} = \mathbf{L} + \mathbf{S}$. De spin-baan koppeling wordt in rekening gebracht met een nieuwe term in de hamiltoniaan, $\mathcal{H}_{LS} = \xi(r)\mathbf{L}\cdot\mathbf{S}$. Door deze storing wordt de n^2 ontaarding van de Schrödinger hamiltoniaan $\mathcal{H}_0$ (deels) opgeheven. Omdat $\mathbf{L}\cdot\mathbf{S}$ commuteert met de $\mathcal{H}_0$ kunnen we dit uitrekenen met gewone storingrekening. Omdat $\xi(r)$ niet commuteert met $\mathcal{H}_0$ is deze berekening alleen geldig tot 1e orde in de storingsrekening. Dat is meestal afdoende omdat de tweede orde correctie meestal verwaarloosbaar klein is. Helaas commuteert de $\mathcal{H}_{LS}$ koppelingsterm niet met de Zeeman hamiltoniaan $\mathcal{H}_Z$. Daarom moet de niveausplitsing in een magneetveld uitgerekend worden met storingsrekening voor een ontaard niveau. In veel gevallen is dit mogelijk door het oplossen van een 2×2 seculiervergelijking. Als bijzondere gevallen blijken zowel de lage veld limiet, $\langle\mathcal{H}_Z\rangle \ll \langle\mathcal{H}_{LS}\rangle$, als de hoge veld limiet, $\langle\mathcal{H}_{LS}\rangle \ll \langle\mathcal{H}_Z\rangle$, oplosbaar met eerste orde storingsrekening. Omdat $m_j = m_l + m_s$ een goed kwantumgetal is, ongeacht de sterkte van het magneetveld, is kennis van de *laagveld* en *hoogveld* informatie voldoende om het gehele fijnstructuurdiagram te schetsen.

Thuis bestuderen:

Hoofdstuk 4 - deel 2 (vanaf § 4.4): *Koppeling van impulsmomenten en de Termnotatie (spectroscopische notatie)*, *Clebsch-Gordan decompositie*, *Landé interval regel*, *zwaartepuntsregel*, *laagveld limiet - Landé factor*, *hoogveld limiet - Paschen-Back effect*, *Wigner-Eckart theorema. Screening*, *Effectieve lading*, *Quantum defect*, *Rydberg limiet*, *laagveld limiet - Landé factor*, *hoogveld limiet - Paschen-Back effect.*

§ 4.4: Hamiltoniaan voor de fijnstructuur:

- § 4.4.1: De introductie van het totaal impulsmoment $\mathbf{J} = \mathbf{L}+\mathbf{S}$ met de bijbehorende *gekoppelde* basis $\{|lsjm_J\rangle\}$ meestal kort genoteerd als $\{|jm_j\rangle\}$ en het herschrijven van deze basis in termen van de *ontkoppelde* basis $|lm_lsm_s\rangle \equiv |lm_l\rangle \otimes |sm_s\rangle$ (de *Paschen-Back basis*) door middel van een *Clebsch-Gordan decompositie.* In deze paragraaf wordt de stof van § 3.2 toegepast. Kijk goed hoe de commutatierelaties worden bewezen: Problem 4.4-4.7. Problem 4.8 is *heel belangrijk!*
- § 4.4.2: Bestudeer hoe het *bewegingsgeïnduceerde* veld $\mathbf{B}_L$ ontstaat.
- § 4.4.3: Bestudeer hoe $\mathbf{B}_L$ reduceert tot het *spin-baan veld* $\mathbf{B}_{LS}$ door te corrigeren voor de *Thomas precessie.* Door de spin te koppelen aan het veld $\mathbf{B}_{LS}$ ontstaat de spin-baan wisselwerking.
- § 4.4.4: Bestudeer hoe de spin-baan hamiltoniaan $\mathcal{H}_{LS} = \xi(r)\mathbf{L}\cdot\mathbf{S}$ tot stand komt, i.h.b. hoe de koppelingssterkte $\xi(r)$ gedefinieerd is.
- § 4.4.5: Door alle genoemde termen te verzamelen verkrijgen we de fijnstructuur hamiltoniaan.

§ 4.5: De fijnstructuur in nulveld.

- § 4.5.1: Bestudeer hoe de *effectieve* fijnstructuur hamiltoniaan tot stand komt, i.h.b. hoe de koppelingsconstante ζ_{nl} gedefinieerd is.
- § 4.5.2: Bestudeer Fig. 4.8 en zorg dat je de verschuivingsregels van de spin-baan wisselwerking kunt afleiden. Neem kennis van de *Landé interval regel,* $\Delta W_j = \Delta E^{LS}_{n,j} - \Delta E^{LS}_{n,j-1} = \zeta_{nl}j$, en de *zwaartepuntsregel* voor energieniveaus. Begrijp wat bedoeld wordt met een gestrekte toestand. Problem 4.9 is facultatief. Bereken de fijnstructuursplitsing en controleer de zwaartepuntsregel voor waterstofachtige atomen.

- § 4.5.3: *Waterstof* - Bestudeer waarom de fijnstructuurniveaus van waterstof alleen van j afhangen en niet van l en/of s afzonderlijk.

§ 4.6: We gaan nu naar de *alkali-achtige atomen.*

- § 4.6.1: We buigen we ons over een van de grote puzzels uit de uit de ontwikkeling van de Atoomfysica (zie Fig. 4.9): waarom zijn twee kwantumgetallen (n, j) afdoende voor waterstof maar hebben we er drie nodig $(n, l,$s) voor de alkali atomen?
- § 4.6.2: Begrijp dat de $n\,^2S - n\,^2P$ splitsing in alkalis enorm groot is omdat de kernlading door core elektronen beter wordt afgeschermd voor p elektronen dan voor s elektronen. Waterstof heeft geen core elektronen. Hierdoor treedt een (bijna complete) toevallige ontaarding op van van de $n\,^2S$ en de $n\,^2P$ termen. Bestudeer Fig. 4.10*a* . Merk op dat de spin-baan koppeling groot is in de zware alkalis. Dit komt door de grote kernlading (die ondanks de afscherming door de core elektronen zich toch doet gelden).
  - § 4.6.2.1: Begrijp wat er bedoeld wordt met de begrippen *screening constante*, *effectieve kernlading* en *kwantum defect.* Bestudeer Fig. 4.10*b*, Fig. 4.11 en Tabel 4.1 Begrijp wat er bedoeld wordt met de *Rydberg limiet* van het kwantum defect.
  - § 4.6.2.2: Hier kun je lezen wat er met een atoom gebeurd als je de kernlading groter maakt. Begrijp wat er bedoeld wordt met een iso-elektronische reeks. Deze paragraaf is belangrijk om later opvallende anomalieën in het periodieke systeem te kunnen begrijpen. Heel belangrijk: begrijp waarom s toestanden preferentieel gebonden worden. Bestudeer Fig. 4.12.
- § 4.6.3: (*facultatief*) Screening heeft ook invloed op de fijnstructuur.
- § 4.6.4: (*facultatief*) Deze paragraaf is heel waardevol voor studenten die optische dipool overgangen tussen fijnstructuurniveaus willen kunnen uitrekenen.

§ 4.7: Nu gaan we een magneetveld aanleggen.

- § 4.7.1: Lees de introductie. Als we te maken hebben met een ontaard niveau en twee niet commuterende storingsoperatoren (H_Z en H_{LS}) dan moeten we de seculiervergelijking oplossen. Dit is equivalent met het diagonaliseren van de storingsmatrix.
- § 4.7.2: We schrijven de elementen van de storingsmatrix in de ongekoppelde basis (Zeeman basis), $\mathcal{H}'_{m_j m'_s m_s} = \langle nlm'_l s m'_s | \mathcal{H}' \, | nlm_l s m_s \rangle$. Merk op dat alle matrixelementen waarin m_s en m'_s met meer dan één eenheid van impulsmoment verschillen nul zijn.
- § 4.7.3: Het belangrijkste is dat je inziet dat de matrix bestaat uit (1×1) blokken en (2×2) blokken langs de diagonaal. We hoeven dus nooit meer dan een (2×2) matrix te diagonaliseren. Begrijp het verschil tussen zuivere spintoestanden (lineaire Zeemanverschuiving) en gemengde spintoestanden (niet-lineaire Zeemanverschuiving). Neem goed kennis van het kantelgedrag van laag veld naar hoog veld in Fig. 4.15. Problem 4.12 biedt een relatie voor het kantelpunt, handig is om in te schatten wanneer je in waterstof de *laagveld* limiet verlaat.
- § 4.7.4: Bestudeer de *hoogveld* limiet, waarbij je gebruik maakt van de ontkoppelde basis (Paschen-Back basis) met de spin-baan hamiltoniaan $\mathcal{H}_{LS}$ als storing. Dit kan beschreven worden met eerste orde storingsrekening. Deze sectie is heel belangrijk.
- § 4.7.5: Bestudeer de *laagveld* limiet, waarbij je gebruik maakt van de gekoppelde basis met de Zeeman hamiltoniaan $\mathcal{H}_Z$ als storing. Ook deze limiet kan beschreven worden met eerste orde storingsrekening. Ook deze sectie is heel belangrijk. Het Wigner-Eckart theorema in de vorm van Eq. (4.200) moet je kennen maar de algebraïsche afleiding valt buiten de tentamenstof (Problem 4.14 en Appendix K). Wel moet je de heuristische afleiding via het vectordiagram (Fig. 4.6) en Eq. (4.200) begrijpen en kunnen reproduceren. Zorg er ook voor dat je de afleiding van de Landé factor g_J begrijpt.

§ 10.7.5: Bestudeer deze paragraaf als een voorbeeld van de *laagveld* limiet. Problem 4.14 biedt een afleiding van het Wigner-Eckart theorema voor het speciale geval van L_z. Dit bewijs is facultatief maar geeft je een idee van hoe het volledige bewijs in elkaar steekt.

Parate kennis:

1. Realiseer je twee belangrijke zaken over commutatierelaties:
   - als A commuteert met C én B commuteert met C *houdt dit niet automatisch in* dat A ook met B commuteert. Voorbeeld: $[L_z, \mathbf{L}^2] = 0$ en $[\mathbf{L}\cdot\mathbf{S}, \mathbf{L}^2] = 0$ maar $[L_z, \mathbf{L}\cdot\mathbf{S}] \neq 0$.
   - als A *niet* commuteert met C én B *ook niet* commuteert met C kan het best zo zijn dat $A+B$ *wel* met C commuteert. Voorbeeld: $[L_z, \mathbf{L}\cdot\mathbf{S}] \neq 0$ en $[S_z, \mathbf{L}\cdot\mathbf{S}] \neq 0$ maar $[J_z, \mathbf{L}\cdot\mathbf{S}] = [L_z + S_z, \mathbf{L}\cdot\mathbf{S}] = 0$.
2. Het *vectorkoppelingsdiagram* (Fig. 3.9 en Fig. 4.6) met *driehoeksongelijkheid* en de *spectroscopische Term notatie.*
3. De *Clebsch-Gordan decomposities*

$$|jm_j\rangle = \sum_{m_l=-l}^{l}\sum_{m_s=-s}^{s} |lm_lsm_s\rangle\langle lm_lsm_s\,|jm_j\rangle$$
$$|lm_lsm_s\rangle = \sum_{j=|l-s|}^{l+s}\sum_{m_j=-j}^{j} |jm_j\rangle\,\langle jm_j\,|lm_lsm_s\rangle\,.$$

4. De *Landé interval regel (inclusief afleiding):* $\Delta W = \Delta E^{LS}_{n,J} - \Delta E^{LS}_{n,J-1} = \zeta_{nl} J$.
5. De *zwaartepuntsregel:*

$$\frac{1}{(2l+1)\,(2s+1)}\sum_{J=|l-s|}^{l+s}(2J+1)\,\Delta E^{LS}_{n,J} = 0.$$

6. Screening door core elektronen: de rotationele structuur blijft intact (behoud van centrale symmetrie).
7. Ben bekend met de concepten *quantum defects* en *screening efficiency* en *iseoelectronic pairs.*
8. Begrijp de voorkeursbinding van s elektronen.
9. Begrijp hoe screening de fijnstructuur beïnvloedt en in het bijzonder de spin-orbit koppeling. Begrijp dat het energie verschil tussen D1 en D2 transities in alkalis snel toeneemt met Z, maar niet zo snel als verwacht door de screening.
10. De storingsrekening voor hoog veld.
11. De storingsrekening voor laag veld inclusief het Wigner-Eckart theorema

$$\langle nlsJm_J|\,L_z\,|nlsJm_J\rangle = \langle lsJ\,\|L\|\,lsJ\rangle\,\langle Jm_J|\,J_z\,|Jm_J\rangle$$
$$\langle nlsJm_J|\,S_z\,|nlsJm_J\rangle = \langle lsJ\,\|S\|\,lsJ\rangle\,\langle Jm_J|\,J_z\,|Jm_J\rangle\,,$$

met

$$\langle nlsJm_j|\,L_z\,|nlsJm_j\rangle = \frac{\langle lsJm_j|\,(\mathbf{L}\cdot\mathbf{J})\,J_z\,|lsJm_j\rangle}{\langle lsJm_j|\,\mathbf{J}^2\,|lsJm_j\rangle} = \langle lsJ\,\|L\|\,lsJ\rangle\,\langle lsJm_j|\,J_z\,|lsJm_j\rangle\,,$$

waarbij

$$\langle lsJ \,\|L\|\, lsJ\rangle = \frac{\langle lsJm_j|\, \mathbf{L}\cdot\mathbf{J}\, |lsJm_j\rangle}{\langle lsJm_j|\, \mathbf{J}^2\, |lsJm_j\rangle} = \frac{J(J+1)+l(l+1)-s(s+1)}{2J(J+1)}.$$

en de analoge uitdrukking voor S_z.

12. De uitdrukking en de afleiding van de Landé factor

$$g_J = g_L\langle lsj \,\|L\|\, lsj\rangle + g_e\langle lsj \,\|S\|\, lsj\rangle \simeq 1 + \frac{j(j+1)+s(s+1)-l(l+1)}{2j(j+1)}.$$

5 Hyperfine structure of hydrogen-like atoms - deel 1

De kern heeft spin $\mathbf{I}$ en daarmee geassocieerd een magnetisch moment $\boldsymbol{\mu}_I = \gamma_I \mathbf{I}$ met een gyromagnetische verhouding γ_I die (afhankelijk van de kern) zowel positief als negatief kan uitvallen. Dit geeft aanleiding tot het kern-Zeeman effect met als effectieve hamiltoniaan

$$\mathcal{H}_Z = \gamma_I \, \mathbf{I} \cdot \mathbf{B}.$$

Als gevolg van het magnetisch moment van de kern is er altijd een intern magneetveld. Dit geeft aanleiding tot een koppeling, de hyperfijninteractie, tussen de kernspin $\mathbf{I}$ en het totaalimpulsmoment $\mathbf{J} = \mathbf{L} + \mathbf{S}$ van het elektron. Deze koppeling kan altijd (in goede benadering) geschreven worden in de vorm

$$\mathcal{H}_{IJ} = a_{\text{hfs}} \, (\mathbf{I} \cdot \mathbf{J})/\hbar^2,$$

maar de koppelingsconstante a_{hfs} heeft een andere oorsprong voor $l = 0$ dan voor $l \neq 0$. De hyperfijnkoppeling geeft aanleiding tot opsplitsing van de fijnstructuurniveaus en dit kunnen we uitrekenen met eerste orde storingsrekening. Net als in het geval van de fijnstructuur vinden we een intervalregel en een zwaartepuntsregel. Tot slot van het eerste deel over hyperfijnstructuur wordt de hyperfijnsplitsing van de waterstof grondtoestand $^2S_{1/2}$ uitgerekend. De nauwkeurigheid blijkt $1 : 10^4$ te zijn. Niet gek voor een derdejaars college over echte atomen!

Thuis bestuderen:

Lees de inleiding. De hyperfijnstructuur vindt zijn oorsprong in de eigenschappen van de atoomkern. Neem kennis van de verschillende bijdragen. Het blijkt dat we de kern slechts oppervlakkig hoeven te begrijpen om de hyperfijnstructuur met grote precisie te kunnen beschrijven. In dit hoofdstuk concentreren we ons op de *magnetische* hyperfijnstructuur.

§ 5.1.1: Net als bij elektron spin associëren we een magnetisch moment met kernspin. Let op de tekenconventies, $\boldsymbol{\mu}_I = \gamma_I \mathbf{I} = g_I \mu_N \, (\mathbf{I}/\hbar)$; realiseer je dat bij de kernspin de g_I factor en de gyromagnetische verhouding $\gamma_I = g_I \mu_N/\hbar$ *positief* dan wel *negatief* kunnen uitvallen. De hamiltoniaan is weer van het generieke type, $\mathcal{H}_Z = -\boldsymbol{\mu}_I \cdot \mathbf{B}$, en het koppel wordt beschreven met $d\mathbf{I}(t)/dt = \boldsymbol{\mu}_I \times \mathbf{B}$.

§ 5.1.2: De introductie van het totaal impulsmoment $\mathbf{F} = \mathbf{J} + \mathbf{I}$ met de bijbehorende *gekoppelde* basis $\{|IJFm_J\rangle\}$, vaak kort genoteerd als $\{|Fm_F\rangle\}$. De koppeling is geïllustreerd in Fig. 5.1. Zoek zelf uit hoe de gekoppelde basis herschreven kan worden in termen van de *ontkoppelde* basis $|Im_I Jm_J\rangle \equiv |Im_I\rangle \otimes |Jm_J\rangle$ (de *Paschen-Back basis*) door middel van een *Clebsch-Gordan* decompositie.

§ 5.2: Magnetische hyperfijnwisselwerking: § 5.2.1: Bestudeer het formuleren van de hamiltoniaan voor de *magnetische* hyperfijnwisselwerking. Fris je kennis van de magnetische dipool-dipool interactie op met behulp van Problem 5.1.

§ 5.2.2: Begrijp de drie bijdragen aan de magnetische hyperfijninteractie $\mathcal{H}_{\text{hfs}}$: (a) de *Fermi-contact interactie* $\mathcal{H}_{\text{Fermi}}$, waarbij $\boldsymbol{\mu}_e$, het magnetisch moment van het elektron, (en daarmee ook de spin $\mathbf{S}$) koppelt aan het magnetisch veld *in* de kern - dit gebeurt alleen voor $l = 0$ (in dit geval is $\mathbf{J} = \mathbf{S}$); (b) de *kernspin-baan koppeling* $\mathcal{H}_{LI}$, waarbij $\boldsymbol{\mu}_I$, het magnetisch moment van de kern, (en daarmee ook de spin $\mathbf{I}$) koppelt aan het magneetveld behorend bij het baanimpulsmoment $\mathbf{L}$ van het elektron - dit veld is alleen aanwezig voor $l \neq 0$, d.w.z. bij aanwezigheid van baanimpulsmoment; (c) de *magnetische dipool-dipool interactie* $\mathcal{H}_{dd}$ tussen het magnetisch moment $\boldsymbol{\mu}_e$ van het elektron (dus ook de spin $\mathbf{S}$) het magnetisch moment $\boldsymbol{\mu}_I$ van de kern (dus ook de spin $\mathbf{I}$) - gemiddeld over de baanbeweging is deze wisselwerking alleen ongelijk aan nul voor $l \neq 0$.

§ 5.2.3: Hier vind je de tensor uitdrukking voor de magnetische dipool-dipool interactie. In Problem 5.2 demonstreren we de decompositie in tensor componenten. *Deze sectie valt buiten de tentamenstof.*

§ 5.3: Hyperfijnwisselwerking in nulveld:

§ 5.3.1: Eerst bestuderen we de hyperfijnwisselwerking in nulveld. We beginnen met een samenvatting om ons voor te bereiden op de afleiding. Het blijkt dat, ondanks de drie bijdragen ($\mathcal{H}_{\text{hfs}} = \mathcal{H}_{LI} + \mathcal{H}_{dd} + \mathcal{H}_{\text{Fermi}}$) de magnetische hyperfijninteractie een extreem eenvoudige vorm heeft: $\mathcal{H}_{\text{hfs}} = a_{\text{hfs}}\,(\mathbf{I}\cdot\mathbf{J})/\hbar^2$. Wel moet men dan voor $l = 0$ een andere uitdrukking voor a_{hfs} gebruiken dan voor $l \neq 0$. Neem dus zorgvuldig kennis van het verschil tussen de uitdrukkingen voor de coëfficiënten a_{hfs} voor de gevallen $l = 0$ en $l \neq 0$. Merk op dat in *beide* gevallen *het teken van* a_{hfs} *wordt bepaald door de gyromagnetische verhouding* γ_I van de kern.

§ 5.3.2: Overtuig jezelf dat de Fermi-contact term de enige term is die een bijdrage geeft voor $l = 0$.

§ 5.3.3: Bestudeer hoe de som van de dipool-dipool interactie en de kernspin-baan interactie een effectief veld $\mathbf{B}_J$ ter plaatse van de kern opleveren. Het uitrekenen van dit veld is vrij technisch, waarbij het Wigner-Eckart theorema een glansrol speelt. In Problem 5.3 laten we zien hoe we het gereduceerde matrix element $\langle nlsj||B_J||nlsj\rangle$ bepalen. Deze afleiding is heel karakteristiek en zeker aanbevolen maar *valt buiten de tentamenstof.*

§ 5.3.4: In deze paragraaf berekenen we de hyperfijnsplitsing in nulveld voor een gegeven fijnstructuur Term $n\,^{2s+1}L_J$. Dit kan met eerste orde storingsrekening omdat $\mathbf{I}\cdot\mathbf{J}$ commuteert met de fijnstructuurhamiltoniaan. Ga na dat de storing inderdaad diagonaal is in de gekoppelde basis $\{|IJFm_F\rangle\}$.

§ 5.3.5: Door de hyperfijnverschuiving van twee opeenvolgende F niveaus van elkaar af te trekken krijgen we de *hyperfijnintervalregel* $\Delta W_F = \Delta E_F^{IJ} - \Delta E_{F-1}^{IJ} = a_{\text{hfs}}F$. De *zwaartepuntsregel* wordt gegeven zonder bewijs maar dit volgt analoog aan Problem 4.9 omdat het spoor van de interactie matrix invariant is onder unitaire transformatie.

§ 5.3.6: Geniet van het uitrekenen van de hyperfijnsplitsing van de waterstofgrondtoestand met een nauwkeurigheid van $1 : 10^4$. Deze overgang heeft een belangrijke rol gespeeld in de tijdmeting en in de radioastronomie!

§ 5.3.7: (*facultatief*) Deze paragraaf is waardevol voor studenten die optische dipool overgangen tussen de niveaus van de hyperfijnstructuur willen kunnen uitrekenen.

Parate kennis:

1. Het *vectorkoppelingsdiagram* (Fig. 5.1.) met *driehoeksongelijkheid.*
2. De *kern-Zeeman hamiltoniaan:*

$$\mathcal{H}_Z = -\boldsymbol{\mu}_I\cdot\mathbf{B} = \gamma_I\,\mathbf{I}\cdot\mathbf{B}$$

3. Begrijp de herkomst van de drie contributies aan de hyperfijninteractie en ken de termen: *nuclear spin-orbit interaction, magnetic dipole-dipole interaction, Fermi contact interaction.*
4. De effectieve hamiltoniaan voor de *hyperfijnkoppeling:*

$$\mathcal{H}_{\text{hfs}} = a_{\text{hfs}}\,(\mathbf{I}\cdot\mathbf{J})/\hbar^2.$$

5. Weten dat het teken van de hyperfijncoëfficiënt a_{hfs} wordt bepaald door gyromagnetische verhouding γ_I

6. De *hyperfijninterval regel: Binnen een fijnstructuur Term* geldt voor de hyperfijnsplitsing
$$\Delta W_F = \Delta E_F^{IJ} - \Delta E_{F-1}^{IJ} = a_{\mathrm{hfs}} F.$$
7. De *zwaartepuntsregel:*
$$\frac{1}{(2I+1)(2J+1)} \sum_{F=|I-J|}^{I+J} \Delta E_F^{IJ} = 0.$$
8. The energiesplitsing van de *hyperfijnniveaus* zijn grofweg een factor m_e/m_p kleiner dan de splitsing van de *fijnstructuur*.

5 Hyperfine structure of hydrogen-like atoms - deel 2

In het tweede deel van het hoofdstuk voegen we de Zeeman interactie toe aan de nulveld hyperfijnhamiltoniaan. In complete analogie met de $\mathbf{L}\cdot\mathbf{S}$ koppeling van de fijnstructuur, commuteert ook de $\mathbf{I}\cdot\mathbf{J}$ koppelingsterm niet met de Zeeman hamiltoniaan $\mathcal{H}_Z$. Daarom moet de niveausplitsing in een magneetveld uitgerekend worden met storingsrekening voor een ontaard niveau. In veel gevallen is dit mogelijk door het oplossen van een 2×2 seculiervergelijking. Als bijzondere gevallen blijken zowel de lage veld limiet, $\langle\mathcal{H}_Z\rangle \ll \langle\mathcal{H}_{\rm hfs}\rangle$, als de hoge veld limiet, $\langle\mathcal{H}_{\rm hfs}\rangle \ll \langle\mathcal{H}_Z\rangle$, oplosbaar met eerste orde storingsrekening.

Thuis bestuderen:

Hoofdstuk 5 - deel 2 (vanaf § 5.4): Aan de orde komen achtereenvolgens *storingsrekening* in de *ongekoppelde* basis, de begrippen *zuivere toestand* en *gemengde toestand*, *hoogveld limiet - Paschen-Back effect*, *laagveld limiet - g_F factor*, *Wigner-Eckart theorema.* Daarna volgt een bespreking van de hyperfijnstructuur van alkali atomen (als voorbeelden van hyperfijnstructuur in één-elektron atomen).

§ 5.4: Hyperfijnstructuur in een aangelegd magneetveld: Neem kennis van de effectieve spin hamiltoniaan van het atoom met zowel fijnstructuur als hyperfijnstructuur. Begrijp wat bedoeld wordt met de *gekoppelde* en de *ongekoppelde* basis van de hyperfijnstructuur en waarom de *gekoppelde basis de laagveld basis* is en waarom de *ongekoppelde basis de hoogveld basis* is. Bestudeer het Zeeman effect bij aanwezigheid van hyperfijnwisselwerking en merk op dat dit geheel analoog gaat aan de fijnstructuur.

§ 5.4.1: In deze paragraaf leiden we uitdrukkingen af voor de diagonaal en de afdiagonale matrixelementen van de hyperfijn storingsmatrix in de ongekoppelde basis; i.e., de Zeeman basis $\{|nIm_Ijm_j\rangle\}$.

§ 5.4.2: Omdat de $\mathbf{I}\cdot\mathbf{J}$ koppeling niet commuteert met de Zeeman hamiltoniaan moeten we storingsrekening voor een ontaard niveau toepassen. Zoals uitgelegd in Appendix H is het hierbij onze taak om de storingshamiltoniaan te diagonaliseren. Dit komt dit neer op het oplossen van de karakteristieke vergelijking van het eigenwaarden probleem (de zgn. seculiervergelijking). We doen dit hier in de *ongekoppelde basis* (we hadden dezelfde oplossingen ook kunnen verkrijgen uitgaande van de gekoppelde basis) omdat de storingsmatrix dan blokdiagonaal is met (1×1) en (2×2) blokken langs de diagonaal. Daarom hoeven we nooit meer dan een (2×2) matrix te diagonaliseren. Dat wordt gedemonstreerd in Appendix H.4. Voor atomen met $J=1/2$ (zoals waterstof) bepalen we niet alleen de energieniveaus maar ook de corresponderende eigentoestanden. Begrijp het verschil tussen zuivere toestanden (lineaire Zeemanverschuiving) en gemengde toestanden (niet-lineaire Zeeman toestanden). Bestudeer in Fig. 5.5 het kantelgedrag van *laagveld* naar *hoogveld*, in het bijzonder het verschil tussen $\gamma_I > 0$ en $\gamma_I < 0$. Merk op dat het kantelpunt $B_{\rm hfs}$ gedefinieerd is als het punt waar de *hoogveld* en *laagveld* raaklijnen elkaar snijden.

§ 5.4.3: Bestudeer de *hoogveld* limiet. Hier maken we gebruik van de regel dat bij aanwezigheid van diagonaaltermen de afdiagonaaltermen slechts in hogere orde een bijdrage leveren aan de storingsrekening. Merk op dat in het geval van waterstof de bovenste hyperfijn niveaus elkaar snijden bij een veld van 16.7 Tesla. Dit gebeurt als de kern Zeemanverschuiving gelijk is aan de nulveldsplitsing.

§ 5.4.4: Bestudeer de *laagveld* limiet. Hier doen we opnieuw een beroep op het Wigner-Eckart theorema (vgl. met nulveld). We vinden dat, in goede benadering, dat de g_F factor wordt gegeven door

$$g_F \simeq \pm g_J \frac{1}{2I+1} \quad \text{voor } F = I \pm 1/2;\ j = 1/2;\ F > 0,$$

waarbij g_J de g factor is van de fijnstructuur Term waarop we storingsrekening doen.

§ 5.4.5: Hier gaan we tot tweede orde in storingsrekening. Dit levert in laag veld een kwadratische correctie op die het kwadratisch Zeeman effect wordt genoemd.

§ 5.5: Hyperfijnstructuur van waterstofachtige atomen in de elektronische grondtoestand: Voorbeelden:

§ 5.5.1: Oplossen seculiervergelijking voor $S = 1/2, I = 1/2, \gamma_I > 0$ (waterstof).

§ 5.5.2: Oplossen seculiervergelijking voor $S = 1/2, I = 1, \gamma_I > 0$ (deuterium, lithium-6).

§ 5.5.3: Oplossen seculiervergelijking voor $S = 1/2, I = 3/2, \gamma_I > 0$ (diverse alkali atomen).

§ 5.5.4: Oplossen seculiervergelijking voor $S = 1/2, I = 4, \gamma_I < 0$ (kalium-40).

Parate kennis:

1. De atomaire hamiltoniaan met zowel fijnstructuur als hyperfijnstructuur,

$$\mathcal{H} = \mathcal{H}_0 + \mathcal{H}_r + \xi\, \mathbf{L}\cdot\mathbf{S} + \left(a_{\text{hfs}}/\hbar^2\right) \mathbf{I}\cdot\mathbf{J} + (g_J\mu_B J_z - g_I\mu_N I_z)B/\hbar$$

2. De storingsrekening voor hoog veld (analoog aan fijnstructuur) in *hoogveld* basis.

3. De storingsrekening voor laag veld inclusief het Wigner-Eckart theorema (analoog aan fijnstructuur)

$$\langle nlsJIFm_F|\, J_z\, |nlsJIFm_F\rangle = \langle JIF\, \|J\|\, JIF\rangle \,\langle Fm_F|\, F_z\, |Fm_F\rangle$$
$$\langle nlsJIFm_F|\, I_z |nlsJIFm_F\rangle = \langle JIF\, \|I\|\, JIF\rangle \,\langle Fm_F|\, F_z\, |Fm_F\rangle\,,$$

$$\langle JIF||J||JIF\rangle = \frac{F(F+1) + J(J+1) - I(I+1)}{2F(F+1)}. \tag{O.3}$$

en de analoge uitdrukking voor I.

4. De uitdrukking voor de g_F factor,

$$g_F = g_J\langle JIF||J||JIF\rangle - g_I(m_e/m_p)\langle JIF||I||JIF\rangle \underset{\text{for } J\neq 0}{\simeq} g_J\langle JIF||J||JIF\rangle$$

en de zeer goede benadering voor $J = 1/2$ atomen met $F \neq 0$

$$g_F \simeq \pm g_J \frac{1}{2I+1} \text{ voor } J = 1/2,\ F \neq 0,$$

waarbij $g_F < 0$ altijd correspondeert met de toestand met de laagste multipliciteit ($F = I - 1/2$) en $g_F > 0$ altijd correspondeert met de toestand met de hoogste multipliciteit ($F = I + 1/2$).

5. Het kunnen schetsen van de hyperfijnstructuur als functie van het magneetveld voor atomen met $J = 1/2$ voor gegeven I en (teken van) γ_I.

6 Elektrische hyperfijnstructuur (facultatief)

NB: Dit hoofdstuk *valt buiten de tentamenstof.*

7 Helium-like atoms

Meteen aan het begin van dit hoofdstuk leer je dat er heel veel verandert als een atoom meer dan één elektron bevat. Eigenlijk neemt de complexiteit zo sterk toe dat de situatie min of meer hopeloos zou zijn als de elektrostatische interactie niet alles zou overheersen. In de theoretische beschrijving moet de lading van de elektronen met grote precisie over het atoom verdeeld worden. Dit vraagt een nieuwe aanpak omdat analytische oplossingen (zoals bij waterstof) niet bestaan. Daarnaast wordt de elektrostatische interactie sterk beïnvloed door het fenomeen *exchange* dat geheel afwezig is in de klassieke elektriciteitstheorie. In het eerste college komen we daar weliswaar nog niet aan toe maar de voorkennis dat elektrostatische effecten dominant zijn geeft de burger moed om grote atomen aan te pakken. We zullen zien dat de centrale symmetrie grotendeels gehandhaafd blijft zodat we de classificatie met de quantumgetallen n, l, m_l per elektron kunnen blijven hanteren. Nadat we de nomenclatuur hebben opgefrist beginnen we met het helium atoom. De elektrontoestanden lijken erg op die uit het waterstofatoom. Het grote verschil zit in de Coulombafstoting tussen de elektronen. De invloed daarvan rekenen we uit met eerste orde storingsrekening.

Na helium in de grondtoestand gaan we in dit college kijken naar het geval van helium met twee elektronen in verschillende baantoestanden. Het blijkt dat in dit geval de energie van de twee-elektron-toestand ontaard is onder verwisseling van de elektronen. Dit wordt exchange ontaarding genoemd. We leren dat de Coulombafstoting tussen de elektronen aanleiding geeft tot het opheffen van de ontaarding en maken kennis met twee *Coulomb integralen*: de *directe integraal* $\mathcal{J}$ en de *exchange integraal* $\mathcal{K}$. Met eerste orde storingsrekening van een tweevoudig ontaard niveau vinden we dat de antisymmetrische baangolffunctie de laagste energie heeft. Dit is intuïtief begrijpelijk omdat de Coulombafstoting daar het kleinste is. In het geval van twee elektronen in dezelfde orbitaal (zoals in de helium grondtoestand) speelt alleen de *directe integraal* een rol omdat in dit geval exchange ontaarding niet bestaat. Daarna leren we hoe we de Coulomb integralen kunnen uitrekenen. Tot slot gebruiken we de opgedane kennis om de energie van de grondtoestand van helium uit te rekenen.

Thuis bestuderen:

Lees de introductie.

§ 7.1: We stellen de hamiltoniaan op voor een atoom met exact twee elektronen, een zgn. heliogeen atoom. Eerst bepalen we de oplossingen van het ongestoorde probleem (de Coulombafstoting wordt verwaarloosd). We vinden waterstofachtige energieniveaus.

§ 7.1.1: De Coulombafstoting van de elektronen doet de ladingsverdeling van de elektronen opzwellen - see Fig. 7.1. Dit opzwellen kan ook verklaard worden door in rekening te brengen dat het ene elektron de kernlading enigszins afschermt voor het andere elektron. Dit wordt screening genoemd. We berekenen de energie van het atoom met eerste orde storingsrekening. De *afschermpotentiaal*, $U_{1s}(\rho)$, gevoegd bij de *Coulomb potentiaal* van de kale kern, $-Z/\rho$, vormt de *effectieve centrale veld potentiaal*, $U_{\rm CF}(\rho)$, - see Eq. (7.17)

$$U_{\rm CF}(\rho) = -\frac{Z}{\rho} + U_{1s}(\rho) = -\frac{1}{\rho}\left[Z - \sigma_{1s}(\rho)\right] = -\frac{Z_{1s}(\rho)}{\rho}.$$

Hier is $Z_{1s}(\rho) = [Z - \sigma_{1s}(\rho)]$ de *effective kernlading* op afstand ρ van de kern, met Z de kernlading (in atomaire eenheden) en $\sigma_{1s}(\rho)$ de *afschermlading* op afstand ρ van de kern. Bestudeer deze grootheden in Fig. 7.2.

§ 7.1.2: Een lagere energie van de grondtoestand kan verkregen worden door de golffunctie door variatie te optimaliseren.

§ 7.1.3: De afscherming is niet compleet. Daarom is het mogelijk om een elektron aan een *neutraal* waterstofatoom te binden; zo krijgen we het negatieve ion H^-. De binding van dit ion kan niet met storingsrekening worden verkregen maar wel met variatierekening. Het uitvoeren van de variatierekening voor het H^- ion valt buiten de tentamenstof maar je moet wel begrijpen waarom H^- als ion kan bestaan.

§ 7.1.4: Onze taak is om de beste effectieve potentiaal te vinden. In deze paragraaf laten we zien dat voor de $1s^2$ productgolffunctie van helium variatierekening leidt tot de *Hartree vergelijkingen*. Dit is een set van gekoppelde Schrödinger vergelijkingen (één voor elk elektron) waarvan de oplossing met een iteratieve numerieke procedure verkregen moet worden. Omdat de golffuncties de potentiaal bepalen (die in de Schrödinger vergelijking voorkomt) zijn iteraties zijn nodig om een *zelfconsistente oplossing* (voor golffuncties en potentiaal) te krijgen. De afleiding van de Hartree vergelijkingen valt buiten de tentamenstof maar het principe van de zelfconsistente oplossing moet je begrijpen.

§ 7.2: Hier leren we dat de grondtoestand van helium (met twee elektronen in *dezelfde* baangolffunctie) niet magnetisch is ($S = 0$) alhoewel de magnetische toestand ($S = 1$) op basis va de koppelingsregels voor twee elektron spins heel goed mogelijk zou kunnen zijn (zie Sectie 3.2). Het experiment dwingt ons om de symmetrische spintoestand uit te sluiten. Dit wordt het *Pauli uitsluitingsbeginsel* genoemd.

§ 7.3: Als twee elektronen zich in *verschillende* baangolffuncties bevinden treedt *exchange ontaarding* op (bij verwaarlozing van de Coulombafstoting tussen de elektronen). Het opheffen van deze ontaarding door de Coulombafstoting kan uitgerekend worden met storingsrekening van een tweevoudig ontaard niveau. De gestoorde toestanden zijn de symmetrische en antisymmetrische lineaire combinaties van de ongestoorde toestanden. We introduceren de *directe integraal* $\mathcal{J}$ en de *exchange integraal* $\mathcal{K}$. De directe integraal geeft aanleiding tot een *verschuiving* van de ontaarde energieniveaus. De exchange integraal zorgt voor de *opsplitsing*. De antisymmetrische baangolffunctie heeft de laagste energie omdat de Coulombafstoting daar het kleinste is. We constateren dat - experimenteel - de antisymmetrische baantoestand alleen wordt waargenomen in combinatie met een symmetrische spintoestand en *vice versa*. Andere combinaties moeten dus worden uitgesloten (Pauli uitsluitingsbeginsel).

§ 7.4: Bestudeer hoe de storingsterm uit de hamiltoniaan (de Coulombafstoting tussen de elektronen) herschreven kan worden als een som over bolfuncties en ga na hoe dit leidt tot uitdrukkingen voor $\mathcal{J}$ en $\mathcal{K}$ in termen van hoekintegralen en radiale integralen.

§ 7.4.1: Overtuig jezelf dat de hoekintegralen $a^k(lm_l; l'm_{l'})$ en $b^k(lm_l; l'm_{l'})$ eenvoudig uit te rekenen zijn door toepassing van de integraal over drie bolfuncties - zie Eq. (L.59) en Problem 7.3). Tabel 7.1 is belangrijk. Later, bij het onderbouwen van de Hund regels, zal blijken dat je de tabel snel moet kunnen gebruiken.

§ 7.4.2: Bestudeer hoe de radiale integralen $F^k(nl; n'l')$ en $G^k(nl; n'l')$ compact kunnen worden geschreven door het introduceren van mean-field potentialen (afschermpotentialen). Problems 7.8 en 7.9 belangrijk om later de Hund regels te kunnen onderbouwen.

§ 7.4.3: Bereken de grondtoestandsenergie van helium.

§ 7.4.4: Bereken de grondtoestandsenergie van metastabiel triplet helium.

§ 7.4.5: Lees het stukje over helium-achtige atomen en begrijp waarom metastabiele toestand van helium een bijzondere plaats inneemt.

Parate kennis:

1. De naam en definitie van de grootheden: *baangolffunctie* (orbitaal), *schillen* en *subschillen*, *equivalente elektronen*, *Pauli principe*, *elektron configuratie, volle schil, gaten, valentie elek-*

tronen en *core elektronen*.

2. De hamiltoniaan van het heliumatoom in Hartree atomaire eenheden

$$\mathcal{H} = \sum_{i=1,2} \mathcal{H}_i + \mathcal{H}' = \sum_{i=1,2} \left(-\frac{1}{2}\boldsymbol{\nabla}_i^2 - \frac{Z}{\rho_i} \right) + \frac{1}{\rho_{12}}.$$

3. De opbouw van de *effectieve potentiaal voor het centrale veld*,

$$U_{\mathrm{CF}}(\rho) = -\frac{Z}{\rho} + U_{1s}(\rho) = -\frac{1}{\rho}\left(Z - \sigma_{1s}\right) = -\frac{Z_{1s}(\rho)}{\rho},$$

met $Z_{1s}(\rho) = (Z - \sigma_{1s}(\rho))$ de *effective kernlading* op afstand ρ, Z de *kernlading* en $\sigma_{1s}(\rho)$ de *afschermlading* op afstand ρ (alles in atomaire eenheden).

4. De naam en definitie van de *directe integraal* $\mathcal{J}$ en de *exchange integraal* $\mathcal{K}$

$$\begin{aligned}
\mathcal{J} &= (nlm_l; n'l'm_{l'}|\frac{1}{\rho_{12}}|nlm_l; n'l'm_{l'}) = \sum_{k=0}^{\infty} a^k(lm_l; l'm_{l'})F^k(nl; n'l') \\
\mathcal{K} &= (nlm_l; n'l'm_{l'}|\frac{1}{\rho_{12}}|n'l'm_{l'}; nlm_l) = \sum_{k=0}^{\infty} b^k(lm_l; l'm_{l'})G^k(nl; n'l').
\end{aligned}$$

5. Voor equivalente elektronen $G^k(nl; nl) = F^k(nl; nl) > 0$ en omdat $b^k(lm_l; l'm_{l'}) \geq 0$ voor alle waarden van k, is de exchange integraal positief definiet: $\mathcal{K}(nlm_l; nlm_l') > 0$.

8 Central field approximation for many-electron atoms

In dit hoofdstuk gaan we verder met de aanpak die zo succesvol bleek voor helium. We ontmoeten opnieuw de elektrostatische afscherming van de kernlading (*nuclear screening*) en de *centrale symmetrie.* Daarom komen de bekende orbitalen $1s$, $2p$, $3d, \cdots$ opnieuw langs. We laten zien dat het begrip screening eenvoudig uitgebreid kan worden tot veel-elektron atomen. Daarbij wordt duidelijk dat we de Hamiltoniaan kunnen reduceren tot een centrale potentiaal (§ 8.1) door de *correlaties* tussen de elektronen te verwaarlozen. Vervolgens bespreken we een viertal voorbeelden van zo'n *centrale veld benadering.* Allereerst behoort daartoe het atoommodel met *niet-wisselwerkende* elektronen (§ 8.2). Het tweede voorbeeld van een centrale veldbenadering is het *Thomas-Fermi model* voor het atoom (§ 8.3). Vervolgens bespreken in§ 8.4 de *Hartree vergelijkingen* waarvan we een voorproefje hebben gehad bij de bespreking van helium. De Hartree aanpak kan gezien worden als de eerste aanzet tot een moderne *mean-field* theorie. Als laatste voorbeeld bespreken in§ 8.5 we de semi-empirische *kwantum-defect aanpak* van Bates en Damgaard, waarmee de overgangsdipolen voor optische dipool overgangen in één-elektron atomen ingeschat kunnen worden. Achteraf beschouwd geeft de centrale veld benadering de rechtvaardiging voor het behandelen van alkali atomen als waterstofachtige atomen zoals we gedaan hebben in eerdere hoofdstukken, in het bijzonder bij de bespreking van de hyperfijnstructuur in Hoofdstuk 5.

Thuis bestuderen:

Lees de introductie.

§ 8.1: Bestudeer hoe we een screening potentiaal introduceren en welke termen worden weggelaten in de *centraal-veld benadering.* Kijk of je begrijpt dat je met deze benadering de *correlaties* tussen de elektronen verwaarloost.

§ 8.2: Bestudeer het stukje over atomen waarin de wisselwerking tussen de elektronen verwaarloosd wordt. Constateer dat zelfs onder deze grove benadering de volgorde in het periodiek systeem goed beschreven wordt voor de lichte atomen. Alleen de eerste alinea behoort tot de tentamenstof.

§ 8.3: (*facultatief*) Het Thomas-Fermi centrale veld, het atoommodel van Thomas-Fermi en Thomas-Fermi screening.

§ 8.4: Neem kennis van het principe van een *zelfconsistente mean field oplossing.* Begrijp wat bedoeld wordt met de Hartree vergelijkingen.

§ 8.5: (*facultatief*) Alkali-achtige atomen lenen zich bij uitstek voor een beschrijving met een centrale veld benadering. Een semi-empirische beschrijving wordt mogelijk door het benoemen van een *kwantum defect*, ook bekend onder de naam *Rydberg correctie.*

  § 8.5.1: (*facultatief*) Deze paragraaf gaat over het schatten van radiale integralen met de methode van Bates en Damgaard.

Parate kennis:

1. Alle genoemde definities: *nuclear screening, centrale symmetrie*, *centrale veld benadering, niet-wisselwerkende elektronen, Hartree mean field*, *zelfconsistente oplossing*, *kwantum defect* (*Rydberg correctie).*

2. De N-elektron hamiltoniaan voor de hoofdstructuur van veel-elektron atomen:

$$\mathcal{H} = \sum_{i=1}^{N} \left(-\frac{\hbar^2}{2m_e}\nabla_i^2 - \frac{Ze^2}{4\pi\varepsilon_0 r} \right) + \frac{1}{2}\sum_{i,j}^{N}{}' \frac{e^2}{4\pi\varepsilon_0 r_{ij}}.$$

3. De centrale veld hamiltoniaan

$$\mathcal{H}_{\mathrm{CF}} \equiv \sum_{i=1}^{N} \left(-\frac{\hbar^2}{2m_e} \nabla_i^2 + \mathcal{V}_{\mathrm{CF}}(r_i) \right),$$

met het centrale veld gegeven door

$$\mathcal{V}_{\mathrm{CF}}(r_i) = -\frac{Ze^2}{4\pi\varepsilon_0 r_i} + \mathcal{V}_{\mathrm{scr}}(r_i) = -\frac{e^2}{4\pi\varepsilon_0} \frac{Z_{\mathrm{eff}}(r_i)}{r_i}.$$

4. Notatie: De som over alle *verschillende* paren met $i, j \in \{1, \cdots N\}$ kan geschreven worden op twee equivalente manieren:

$$\tfrac{1}{2} \sum_{i,j=1}^{N}{}' \equiv \sum_{i>j}^{N},$$

waar het accent geeft aan dat de termen met $i = j$ worden uitgesloten en de factor $\frac{1}{2}$ wordt toegevoed om te corrigeren voor dubbel tellen. In te alternatievbe notatie sommerwen we alleen over paren met $i > j$.

9 Many-electron wavefunctions

Hoofdstuk 9 bestaat uit heel droge stof maar is belangrijk omdat duidelijk wordt waarom een veel-elektron probleem formeel hanteerbaar kan blijven. We ontwikkelen het gereedschap om veel-deeltjes systemen van fermionen kwantum mechanisch te beschrijven. We kijken we nog een keer goed naar het begrip *exchange*. We beginnen met het introduceren van de verwisselingsoperator $\mathcal{P}$ (*exchange operator*) en constateren dat dit een *observabele* is met eigenwaarden ±1 en symmetrische (+1) dan wel antisymmetrische (−1) eigentoestanden. Identieke deeltjes blijken zich altijd in één van de twee eigentoestanden van de exchange operator te bevinden. We geven ze een naam: *bosonen* (+1) of *fermionen* (−1). De consequentie van de antisymmetrie van de golffunctie is dat twee fermionen zich niet in dezelfde toestand kunnen bevinden. De elektronen zijn fermionen en dit manifesteert zich als het Pauli principe.

De veel-elektron toestanden kunnen worden geschreven als *Slaterdeterminanten.* Daarom moeten we de verwachtingswaarden van operatoren tussen twee Slaterdeterminanten kunnen uitrekenen. Bijvoorbeeld: wat is het impulsmoment van zo'n toestand? We leiden af dat de matrixelementen waarbij een operator tussen twee Slaterdeterminanten staat altijd gereduceerd kan worden tot een relatief eenvoudige uitdrukking. In principe kan zo'n N-deeltjes matrixelement geschreven worden als een som van $N! \times N!$ termen maar gelukkig blijken de meesten daarvan nul en de rest óf allemaal gelijk te zijn aan elkaar óf aan een overzichtelijk aantal karakteristieke waarden. Voor *ééndeeltjesoperatoren* zijn dat uitdrukkingen waarin alleen één-deeltjes matrixelementen voorkomen, die maximaal N verschillende waarden kunnen aannemen; voor *tweedeeltjesoperatoren* zijn dat uitdrukkingen waarin alleen matrixelementen van deeltjesparen voorkomen, die óf gelijk zijn aan een *directe* waarde óf aan een *exchange* waarde. Er zijn maximaal $N(N-1)$ van dat soort termen.

Thuis bestuderen:

§ 9.1: Bestudeer de definitie van de exchange operator $\mathcal{P}$ en begrijp dat dit een *observabele* is met eigenwaarden ±1. Ga na dat $\mathcal{P}$ commuteert met de hamiltoniaan en dat de gemeenschappelijke basis bestaat uit de symmetrische (+1) dan wel antisymmetrische (−1) eigentoestanden van de hamiltoniaan. We komen tot de conclusie dat twee identieke deeltjes zich altijd in één van de eigentoestanden van de exchange operator bevinden. Die geven we een naam, bosonen (+1) of fermionen (−1). Experimenteel blijken de elektronen fermionen te zijn. De consequentie van de antisymmetrie van de golffunctie is dat twee fermionen zich niet in dezelfde toestand kunnen bevinden (Pauli uitsluitingsbeginsel). Bestudeer de consequentie van de aanwezigheid van spin: als de baangolffunctie symmetrisch (antisymmetrisch) is kan de spintoestand alleen antisymmetrisch (symmetrisch) zijn om te garanderen dat de totale paartoestand antisymmetrisch onder verwisseling van deeltjes inclusief spin.

§ 9.1.1: Begrijp het begrip *spinorbitaal*, de één-electron eigentoestand inclusie spin. Hiervoor gebruiken we een compacte notatie,

$$|\dot{u}\rangle \equiv |u\!\uparrow\rangle \equiv |u\rangle \otimes |\!\uparrow\rangle \qquad \text{and} \qquad |\overline{u}\rangle \equiv |u\!\downarrow\rangle \equiv |u\rangle \otimes |\!\downarrow\rangle\,.$$

Ga na dat een twee-elektron toestand altijd geschreven kan worden als een lineaire combinatie van twee 2×2 determinanten, zgn. *Slaterdeterminanten.*

§ 9.1.1.1: Hie gaan we de spinorbitalen gebruiken om matrix elementen uit te rekenen. Een goede oefining is om te laten zien dat voor matrix elementen van het type $\langle \dot{u}\overline{v}|\rho_{12}^{-1}|\dot{u}\overline{v}\rangle$ de *exchange* termen verdwijnen, terwijl voor het type $\langle \dot{u}\overline{v}|\rho_{12}^{-1}|\dot{v}\overline{u}\rangle$ dit geldt voor de directe termen (zie Problems 9.2 en 9.3),

$$\langle \dot{u}\overline{v}|\rho_{12}^{-1}|\dot{u}\overline{v}\rangle = (uv|\rho_{12}^{-1}|uv) = \mathcal{J}$$
$$\langle \dot{u}\overline{v}|\rho_{12}^{-1}|\dot{v}\overline{u}\rangle = (uv|\rho_{12}^{-1}|vu) = \mathcal{K}.$$

Hier herkennen we de Coulomb-repulsie integralen die we in Hoordstuk 7 voor hydrogene orbitalen hebben leren uitrekenen.

§ 9.1.2: Begrijp dat de Slaterdeterminant eenvoudig gegeneraliseerd kan worden tot een $n \times n$ determinant voor n fermionen. Let op het verschil tussen de *exchange operator* $\mathcal{P}$ en de *permutatieoperator* P,

$$\psi_\alpha (\mathbf{r}_1, \sigma_1; \cdots ; \mathbf{r}_N, \sigma_N) = \sqrt{\frac{1}{N!}} \begin{vmatrix} \varphi_{\alpha_1} (\mathbf{r}_1, \sigma_1) & \cdots & \varphi_{\alpha_N} (\mathbf{r}_1, \sigma_1) \\ \vdots & \dots & \vdots \\ \varphi_{\alpha_1} (\mathbf{r}_N, \sigma_N) & \cdots & \varphi_{\alpha_N} (\mathbf{r}_N, \sigma_N) \end{vmatrix}.$$

De *Slaterdeterminant* is de eenvoudigste generalisatie van de product golffunctie met de juiste permutatiesymmetrie en consistent met het Pauli principe. In de Dirac notatie krijgt deze toestand de vorm

$$|\psi_\alpha\rangle \equiv |\alpha_1, \cdots, \alpha_N\rangle \equiv \sqrt{\frac{1}{N!}} \sum_P (-1)^p P |\alpha_1, \cdots \alpha_N),$$

waarin

$$|\alpha_1, \cdots \alpha_N) \equiv |\alpha_1\rangle_1 \, |\alpha_2\rangle_2 \cdots |\alpha_N\rangle_N \equiv |\psi_\alpha) \tag{O.4}$$

de N-deeltjes geordende product toestand van de één-deeltjes toestanden $|\alpha_\kappa\rangle_i$ is, waarin $\kappa \in \{1, \cdots, N\}$ de *toestandsindex* en $i \in \{1, \cdots, N\}$ *deeltjesindex* wordt genoemd. Zorg ervoor dat je Slaterdeterminant in beide notaties heel goed begrijpt, i.h.b. het verschil in betekenis van de notaties $|\rangle$ en $|)$ voor, respectievelijk, *gesymmetriseerde* en *ongesymmetriseerde* veeldeeltjes toestanden.

§ 9.1.3: Een compacte notatie is essentieel om overzicht te behouden. Begrijp de Dirac notatie $|1, \bar{1}, 0, \bar{0}, -1, -\bar{1}\rangle_{2p^6}$ waarbij we gebruik maken van de *standaard ordeningsconventie*: hoge M_L vóór lage M_L en spin „up" vóór spin „down". Voor volle schillen voldoet slechts één toestand aan het Pauli principe. Overtuig jezelf dat voor een nl^x configuratie er voor ieder elektron $\nu = 2(2l+1)$ toestanden $|nlm_l sm_s\rangle$ mogelijk zijn, evenals ν^2 mogelijke paartoestanden, waarvan er $\binom{\nu}{x}$ voldoen aan het Pauli principe. Een interessante eigenschap van Slaterdeterminanten is dat zij invariant zijn onder unitaire transformatie (zie Problem 9.4).

§ 9.2: Nu we de veel-elektron toestanden kennen kunnen we matrixelementen gaan uitrekenen. Veeldeeltjes operatoren tussen determinant golffuncties lijkt een zware opgave, maar dat zal blijken mee te vallen.

§ 9.2.1: We beginnen met de ééndeeltjesoperatoren.

1. Die zijn allemaal nul als de matrixelementen verschillen in *meer dan één* paar spinorbitalen.
2. Bestudeer dan het stuk over afdiagonale matrixelementen die verschillen in één paar spinorbitalen. Begrijp waarom de meeste termen weer nul zijn. Er blijken $N(N-1)! = N!$ termen niet gelijk aan nul en die zijn allemaal gelijk aan elkaar.
3. Bestudeer vervolgens het stuk over de diagonale matrixelementen. Weer blijken slechts $N!$ termen niet gelijk aan nul. Dit maal kunnen we ze groeperen in N groepjes van $(N-1)!$ termen met dezelfde waarde, d.w.z. er zijn N verschillende termen mogelijk.

§ 9.2.2: Dan gaan we naar de tweedeeltjesoperatoren.

1. Die zijn allemaal nul als de matrixelementen verschillen in *meer dan twee* paar spinorbitalen.

2. Bestudeer het stuk over afdiagonale matrixelementen die verschillen in twee paar spinorbitalen. Begrijp waarom de meesten weer nul zijn. Er blijken slechts $\frac{1}{2}N(N-1)[2(N-2)!] = N!$ termen niet gelijk aan nul en $\frac{1}{2}N(N-1)$ daarvan hebben dezelfde waarde en worden de *directe* termen genoemd en de andere $\frac{1}{2}N(N-1)$ termen zijn ook gelijk aan elkaar en worden de *exchange* termen genoemd. Er zijn dus *twee* verschillende termen mogelijk.
3. Bestudeer dan het stuk over afdiagonale matrixelementen die verschillen in één paar spinorbitalen. We kunnen ze groeperen in N groepjes van $(N-1)!$ termen die voor de helft allemaal een *directe* waarde aannemen en voor de andere helft een *exchange* waarde, d.w.z. er zijn N verschillende waarden mogelijk.
4. Dan komt het stuk over de diagonale matrixelementen. We kunnen ze groeperen in $N(N-1)$ groepjes van $(N-2)!$ termen die weer voor de helft allemaal een „directe" waarde aannemen en voor de andere helft een „ exchange" waarde, d.w.z. er zijn $N(N-1)$ verschillende termen mogelijk.

   Problem 9.5 is belangrijk. Het laat zien dat exchange *nooit* bijdraagt aan een *spin-onafhankelijke* tweedeeltjesinteractie tussen *gepaarde* spins. Dat is handig om paraat te hebben.

§ 9.3: (*voor de liefhebber*) Deze sectie gaat over de aantallenrepresentatie (ook genoemd tweede kwantisatie).

§ 9.3.1: (*voor de liefhebber*) De aantallenrepresentatie vormt de (niet-relativistische) aanzet tot een kwantumveldentheorie voor het atoom. Je moet er even aan wennen maar zodra dat is gebeurd zul je zien dat dat er een enorme vereenvoudiging wordt gerealiseerd. Dat is geen luxe omdat de aanpak van § 9.2 (met alle te onderscheiden gevallen) bewerkelijk is en daarom aanleiding geeft tot fouten. De aantallenrepresentatie is heel intuïtief. De operatoren worden uitgedrukt in zogenaamde *constructieoperatoren.* Hierbij onderscheiden we *creatieoperatoren* en *annihilatieoperatoren.* Deze vormen een generalisatie van de ladderoperatoren voor impulsmoment. Hiermee kun je iedere gewenste atomaire toestand construeren door creatie of annihilatie van spinorbitalen. Dit stuk is *sterk aanbevolen* maar valt *niet* onder de tentamenstof.

§ 9.3.2: (*voor de liefhebber*) We beginnen met het definiëren van een nieuwe representatie: de *aantallenrepresentatie* in de N-deeltjes Hilbert ruimte. In deze representatie geven we aan hoeveel deeltjes (in ons geval elektronen) in een bepaalde toestand zitten. In ons geval specificeren we daarmee de *bezetting* van de spinorbitalen. De veeldeeltjes toestanden noemen we *aantallentoestanden.* In ons geval is dit alleen een andere wijze om een Slaterdeterminant te specificeren. De N-elektron Slaterdeterminant $|\psi_\gamma\rangle$ wordt geschreven als $|\psi_\gamma\rangle \equiv |n_1, n_2, \cdots\rangle$, waarin $n_s \in \{0,1\}$ is het bezettingsgetal van de spinorbitaal $|\alpha_s\rangle$, met $n_r + n_s + \cdots + n_t = N$.

§ 9.3.3: (*voor de liefhebber*) We gaan nu naar de *Grand Hilbert space* (Fock space) waarin de toestanden uit een willekeurig aantal deeltjes kunnen bestaan. De aantallentoestanden uit de vorige paragraaf blijken nu de eigentoestanden van de *aantallen operatoren* $\hat{n}_1, \hat{n}_2, \cdots$, met de *bezettingsgetallen* $n_1, n_2, \cdots$ als de eigenwaarden,

$$\hat{n}_s|n_1, n_2, \cdots, n_s, \cdots\rangle = n_s|n_1, n_2, \cdots, n_s, \cdots\rangle,$$

waarbij $n_1, n_2, \cdots$ de waarden 0 of 1 kunnen aannemen (voor fermionen). De eigentoestanden $|n_1, n_2, \cdots, n_s, \cdots\rangle$ vormen de basis van de *aantallenrepresentatie.* In deze representatie kan iedere operator uitgedrukt worden in termen van de elementaire operatoren $\hat{a}_s^\dagger$ (de *creatie* operator) en $\hat{a}_s$ (de *annihilatie* operator),

$$\begin{aligned} \hat{a}_s^\dagger|n_s,\cdots\rangle &\equiv \sqrt{n_s+1}|n_s+1,\cdots\rangle \\ \hat{a}_s|n_s,\cdots\rangle &\equiv \sqrt{n_s}|n_s-1,\cdots\rangle, \end{aligned}$$

met $n_s \in \{0,1\}$. Door het opleggen van de anticommutatie relaties,

$$\hat{a}_r,\hat{a}_s^\dagger\} = \delta_{rs}\ ; \qquad \{\hat{a}_r,\hat{a}_s\} = \{\hat{a}_r^\dagger,\hat{a}_s^\dagger\} = 0,$$

zorgen we er voor dat het Pauli principe gehandhaafd wordt. Om dit te demonstreren wordt een 7-tal voorbeelden gegeven. Ook de commutatierelaties uit Problem 9.6 zijn heel waardevol.

§ 9.3.4: (*voor de liefhebber*) Na het voorbereidende werk kunnen we de één- en tweedeeltjes operatoren herschrijven in de aantallenrepresentatie

$$Q_1 = \sum_i q_i \quad \rightarrow \quad \hat{Q}_1 = \sum_{s,s'} \langle s'|q|s\rangle \hat{a}_{s'}^\dagger \hat{a}_s,$$

waarbij de som in de uitdrukking voor Q_1 loopt over de *deeltjesindex* en de som in de uitdrukking voor $\hat{Q}_1$ loopt over de *toestandsindex* van alle spinorbitalen (al dan niet bezet) en $\hat{a}_s^\dagger$ en $\hat{a}_s$ zijn de constructieoperatoren waarmee de bezetting van de toestand $|\alpha_s\rangle$ veranderd kan worden. Op vergelijkbare wijze vinden we voor tweedeeltjes operatoren

$$Q_2 = \tfrac{1}{2}\sum_{i,j}{}' q_{ij} \quad \rightarrow \quad \hat{Q}_2 = \tfrac{1}{2}\sum_{t,t'}\sum_{s,s'} (s',t'|q_{12}|s,t)\hat{a}_{s'}^\dagger \hat{a}_{t'}^\dagger \hat{a}_t \hat{a}_s,$$

waarbij $(s',t'|q_{12}|s,t)$ *ongesymmetriseerde* tweedeeltjes toestanden bevat. In de rest van§ 9.3.4 laten we zien dat deze twee operatoren precies doen wat we willen, bijvoorbeeld dat alle gevallen van § 9.2 gereproduceerd worden.

§ 9.4: We gaan nu terug naar de hoofdlijn van de tekst. We passen het veeldeeltjesformalisme toe op impulsmomentoperatoren. Dit stelt ons in staat om impulsmoment eigenschappen van Slaterdeterminanten uit te rekenen.

§ 9.4.1: Hier onderzoeken we de werking van de operatoren L_z, $L_\pm$ en $\mathbf{L}^2$ (van het totale baanimpulsmoment) op Slaterdeterminanten. Voor de spinorbitalen gebruiken we de notatie $|\alpha_k\rangle = |n^k l^k m_l^k s^k m_s^k\rangle$. Het totale baanimpulsmoment is gedefinieerd als

$$\mathbf{L} = \sum_{i=1}^{N} \boldsymbol{l}_i, \tag{O.5}$$

waarbij $\boldsymbol{l}_i$ het baanimpulsmoment van elektron i is.

1. Ga na dat

$$L_z|\psi_\alpha\rangle = \sum_{k=1}^{N} m_l^k \hbar\,|\psi_\alpha\rangle = M_L^\alpha \hbar\,|\psi_\alpha\rangle,$$

precies zoals we intuïtief zouden schrijven...

2. Ga na dat

$$L_\pm|\psi_\alpha\rangle = \sum_{k=1}^{N} \sqrt{l^k(l^k+1) - m_l^k(m_l^k \pm 1)}\hbar\,|\psi_\alpha(m_l^k \pm 1)\rangle,$$

een resultaat dat al iets minder vanzelfsprekend is.

3. Dan komt het geval

$$\mathbf{L}^2|\psi_\alpha\rangle = \left\{ \sum_{k=1}^{N} l^k(l^k+1) + \sum_{k,k'=1}^{N}{}' m_l^k m_l^{k'} \right\} \hbar^2\,|\psi_\alpha\rangle +$$

$$+ \sum_{k,k'=1}^{N}{}' \sqrt{l^k(l^k+1) - m_l^k(m_l^k+1)}\sqrt{l^{k'}(l^{k'}+1) - m_l^{k'}(m_l^{k'}-1)}\hbar^2\,|\psi_\alpha(m_l^k{+}1)(m_l^{k'}{-}1)\rangle.$$

   Hier komen we met intuïtie niet erg ver en wordt de inspanning van § 9.2 beloond.

4. Bestudeer de Problems 9.7 en 9.8 en constateer dat voor het volledig gestrekte baanimpulsmoment ook de uitdrukking voor $\mathbf{L}^2$ weer een intuïtief correcte vorm krijgt. Neem kennis van de commutatie relaties (9.106). De afleiding wordt gegeven in Problems 9.9 en 9.10 maar is facultatief.

§ 9.4.2: Bestudeer hoe de uitdrukkingen nog iets vereenvoudigen voor het geval van spin omdat de spin gelijk is voor alle elektronen ($s = 1/2$).

§ 9.4.3: Merk op dat de l_i^2 operator van de individuele elektronen commuteert met zowel $\mathbf{J}^2$ als met $\mathbf{L}\cdot\mathbf{S}$, waar $\mathbf{J} = \mathbf{L} + \mathbf{S}$.

Parate kennis:

1. De compacte notaties: *helium*:

$$|\psi_{\mathrm{He}}\rangle = |1s, 1\bar{s}\rangle \equiv |0,\bar{0}\rangle_{1s^2} \equiv |\upharpoonleft\!\downharpoonright\rangle_{1s^2},$$

   beryllium:

$$|\psi_{\mathrm{Be}}\rangle = |1s, 1\bar{s}, 2s, 2\bar{s}\rangle \equiv |(0,\bar{0})_{1s^2}(0,\bar{0})_{2s^2}\rangle \equiv |(\upharpoonleft\!\downharpoonright)_{1s^2}(\upharpoonleft\!\downharpoonright)_{2s^2}\rangle,$$

   neon:

$$\begin{aligned} |\psi_{\mathrm{Ne}}\rangle &= |1s, 1\bar{s}; 2s, 2\bar{s}; 2p_1, 2\bar{p}_1, 2p_0, 2\bar{p}_0, 2p_{-1}, 2\bar{p}_{-1}\rangle \\ &= |(0,\bar{0})_{1s^2}(0,\bar{0})_{2s^2}(1,\bar{1},0,\bar{0},-1,-\bar{1})_{2p^6}\rangle \equiv |(\upharpoonleft\!\downharpoonright)_{1s^2}(\upharpoonleft\!\downharpoonright)_{2s^2}(\upharpoonleft\!\downharpoonright\ \upharpoonleft\!\downharpoonright\ \upharpoonleft\!\downharpoonright)_{2p^6}\rangle. \end{aligned}$$

2. De uitdrukking

$$L_z|\psi_\alpha\rangle = \sum_{k=1}^{N} m_l^k \hbar\,|\psi_\alpha\rangle,$$

   en de pendant voor spin impulsmoment.

3. De uitdrukking

$$L_\pm|\psi_\alpha\rangle = \sum_{k=1}^{N} \sqrt{l^k(l^k+1) - m_l^k(m_l^k \pm 1)}\hbar\,|\psi_\alpha(m_l^k \pm 1)\rangle,$$

   en de pendant voor spin impulsmoment.

4. De uitdrukking

$$\mathbf{L}^2|\psi_\alpha^{ll}\rangle = Nl(Nl+1)\hbar^2|\psi_\alpha^{ll}\rangle$$

   voor $\mathbf{L}^2$ in het geval van een gestrekte baanimpulsmoment toestand en zijn pendant voor spin impulsmoment en verder dat deze uitdrukking *volstrekt onjuist* is voor niet volledig gestrekte toestanden.

10 Ground states of many-electron atoms - deel 1

Al het voorbereidende werk is nu gedaan om het periodiek systeem van Mendeleev te begrijpen. Daarbij gaat het om de grondtoestanden van veel-elektron atomen. De theorie die hieraan ten grondslag ligt wordt omschreven als het *Aufbau principe*. De elektronen worden gegroepeerd in *schillen* en *subschillen*. De elektronen in een subschil (vaak gewoon schil genoemd) delen dezelfde radiale golffunctie en worden *equivalent* genoemd. De ontaarding van elektrontoestanden (inclusief spin) bepaalt hoeveel elektronen in een subschil passen. Het maximum aantal wordt bepaald door het *Pauli principe*. De verdeling van de elektronen over de schillen wordt de *electron configuratie* genoemd. Een schil met het maximale aantal elektronen wordt een *volle schil* of *gesloten schil* genoemd. Ontbrekende elektronen in een schil worden *gaten* genoemd. De elektronen buiten de gevulde schillen worden *valentie elektronen* genoemd. De elektronen van de gevulde schillen worden de *core elektronen* genoemd. Hoofdstuk 10 begint met noemen van de „regels van Hund" waarmee de grondtoestand van veel-elektrosystemen bepaald kunnen worden. De regels van Hund hebben geen exacte geldigheid maar zijn zeer geschikt om de onderliggende fysica van het Aufbau principe goed te begrijpen. Zij vormen dan ook de rode draad door dit belangrijke hoofdstuk.

Thuis bestuderen:

Lees de introductie. Begrijp dat het impulsmoment van de grondtoestand van een atoom bepaald wordt door de Coulombafstoting tussen de spinorbitalen.

§ 10.1: neem kennis van de regels van Hund.

§ 10.2: Hartree-Fock methode:

- § 10.2.1: In deze paragraaf wordt een aanzet gemaakt tot het uitrekenen van de energie van de grondtoestand. Bij het uitrekenen van de Coulombafstoting herkennen we een drietal bijdragen: (a) afstoting tussen twee elektronen uit gesloten schillen; (b) de afstoting tussen een valentie elektron en de elektronen van een gesloten schil; (c) de afstoting tussen twee valentie elektronen. Het blijkt dat de afstoting van een $|nlm_l sm_s\rangle$ elektron door de elektronen van een gevulde $n'l'$ schil niet afhangt van de waarden m_l en m_s. Met andere woorden twee *equivalente* elektronen ondervinden altijd dezelfde Coulombafstoting door een gesloten schil. Dit heeft tot gevolg dat *enkel* de *valentie* elektronen bepalen welke toestand de laagste energie heeft.
- § 10.2.2: Begrijp dat niet altijd slechts één enkele configuratie relevant is. Als twee configuraties ongeveer dezelfde energie opleveren worden deze gekoppeld (de configuraties worden gemengd), zoals blijkt uit tweede-orde storingsrekening.
- § 10.2.3: De aanpak van § 10.2.1 kan worden onderbouwd met een variationele procedure, de Hartree-Fock methode. Deze lijkt sterk op de Hartree methode maar is gebaseerd op Slaterdeterminanten zodat impliciet aan het Pauli principe is voldaan. Neem kennis van het begrip *ferromagnetische exchange*. Gezien het belang van de Hartree-Fock methode in de theoretische natuurkunde worden de Hartree-Fock vergelijkingen afgeleid maar *de procedure behoort niet tot de tentamenstof.*
- § 10.2.4: Als je besluit om de Hartree-Fock methode te willen begrijpen lees dan ook het stukje over het theorema van Koopmans. Dit theorema stelt ons in staat om de kwaliteit van de Hartree-Fock methode te toetsen door het meten van foto-emissie van core elektronen.
- § 10.2.5: Als je besluit om de Hartree-Fock methode te begrijpen lees dan ook het stukje over de Slater benadering. Deze benadering geeft een intuïtief inzicht in de rol van de Coulomb integralen.

§ 10.2.6: Deze sectie hoort wel bij de tentamenstof. Het is belangrijk als vervolg op sectie § 10.2.1 en sluit aan bij onze bespreking van helium-achtige atomen. Begrijp dat de Coulomb integralen opgesplitst kunnen worden in termen die de Coulombafstoting *binnen* de schillen (*intra-shell*) beschrijven en termen voor de Coulombafstoting *tussen* de schillen (*inter-shell*). Begrijp ook hoe je die bijdragen kunt uitrekenen met de methoden van Hoofdstuk 7. Problem 10.1 is heel instructief omdat daaruit blijkt dat de interactie energie tussen een valentie elektron en een gesloten schil *niet* afhangt van het magnetisch kwantumgetal van dat elektron.

§ 10.3: Allereerst bespreken we de bolvormige atomen; i.e., atomen *zonder* baanimpulsmoment.

§ 10.3.1: Bij een *volle schil* is zowel het totale baanimpulsmoment als de totale spin nul. Overtuig jezelf hiervan. Neem kennis van het *Unsöld theorema*: volle of halfvolle schillen zijn sferisch. Bestudeer Fig. 10.2. Merk op dat bij gevulde schillen de elektronaffiniteit *nihil* is. Het verschil tussen kleine (ns^2) gevulde schillen (alkali-aard atomen) en grotere (np^2 en nd^2) gevulde schillen is dat de ionisatie energie kleiner is in het eerste geval. Zorg dat je begrijpt waarom de ionisatie energie toeneemt als er meer elektronen in een gesloten schil zitten. Bij de edelgassen Ne en Ar zijn zowel de s schil als de p schil gesloten; bij Kr en Xe zowel de s schil, de p schil en de d schil; bij Rn de s schil, de p schil, de d schil en de f schil. Het wordt dan energetisch zeer onvoordelig om daar een elektron uit te trekken.

§ 10.3.2: Bij een halfgevulde schil is volgens de eerste regel van Hund de spin maximaal gestrekt. Overtuig jezelf ervan dat het totale baanimpulsmoment dan nul moet zijn.

§ 10.4: Nu atomen met één valentie elektron.

§ 10.4.1: De afscherming van de kern is kleiner voor s elektronen dan voor elektronen met $l > 0$. Begrijp waarom dit het geval is en waarom dit aanleiding geeft tot het vullen van de $4s$ schil vóór de $3d$ schil, de $5s$ schil vóór de $4d$ en $4f$ schil, etc., en waarom het energievoordeel van de s schillen marginaal wordt voor bijna half gevulde of geheel gevulde schillen (instorten van de d schil). Begrijp wat bedoeld wordt met *configuratieinteractie*. In deze sectie komen we terug op de screening in alkali-achtige atomen voor toenemende kernlading en hoe dit aanleiding geeft tot het trekken van een gat in de $4s$ schil. Dit is een interessante anomalie die optreedt bij het vullen van de $3d$ schil in de vierde periode van het periodiek systeem.

§ 10.4.2: Hier bespreken we hoe exchange de ladingsverdeling van de core elektronen beïnvloed. Het sleutelwoord is core polarisatie als gevolg van kwantumcorrelaties. Als je het leuk vind kun je hier begrijpen hoe core polarisatie een Fermi contact interactie kan induceren waar je dat niet zou verwachten en hoe dit aanleiding kan geven tot een *negatieve* hyperfijncoëfficiënt bij *positieve* gyromagnetische verhouding ($\gamma_I > 0$). Die inversie treedt op in lithium - zie Fig. 5.3. Het is een opvallende anomalie van de elementaire theorie voor waterstofachtige atomen.

§ 10.5: Het echte werk begint bij atomen met *meer dan één* valentie elektron. Daarbij is het zaak om de eerste twee regels van Hund te begrijpen.

§ 10.5.1: Lees de intro.

§ 10.5.2: Allereerst bestuderen we een partieel gevulde schil met twee equivalente p elektronen. Ga na dat er zonder Pauli uitsluiting $(2l+1)(2s+1) \times (2l+1)(2s+1) = 6 \times 6 = 36$ mogelijke basistoestanden zijn voor zo'n paar, waarvan er $\binom{6}{2} = 15$ consistent zijn met het Pauli principe. Dit zijn de 15 Slaterdeterminanten uit het bovendeel van Tabel 10.2. Dan zien we in dat die 36 toestanden ook neergeschreven kunnen worden als 36 LS

termen in de gekoppelde representatie (onderst deel van Tabel 10.2). Drie vragen komen onmiddellijk op: a.) welke van deze LS termen zijn consistent met het Pauli principe? b.) wat is de relatie tussen de LS termen en de Slaterdeterminanten c.) welke term heeft de laagste energie?

1. a.) Bestudeer de beslissingstabel 10.3 waarmee we bepalen welke LS termen consistent zijn met het Pauli principe. Slechts één triplet blijkt hiermee consistent te zijn en moet (volgens Hund) dus de grondtoestand zijn.
2. b.) Volledig gestrekte toestanden kunnen geschreven worden als één enkele Slaterdeterminant. Als de LS term niet volledig gestrekt is kan hij geschreven worden als lineaire combinatie van Slaterdeterminanten. Welke lineaire combinatie dit is kunnen we bepalen met door een van de operatoren $L_\pm$ of $S_\pm$ te laten werken op een volledig gestrekte toestand. Soms moeten we deze operatoren zelfs meer dan eens laten werken. Bestudeer hoe we uitgaande van de LS termen $|^3P;1,1\rangle$ en $|^1D;2,0\rangle$ twee orthonormale lineaire combinaties van Slaterdeterminanten kunnen vinden. Omdat we te maken hebben met een driedimensionale deelruimte moet de lineaire combinatie van de term $|^1S;0,0\rangle$ (die zich ook in deze deelruimte bevindt) orthogonaal staan op beide andere vectoren. Met deze procedure kunnen we op systematische wijze iedere LS term uitdrukken als een lineaire combinatie van Slaterdeterminanten.
3. c.) Als we onze termen kunnen schrijven als lineaire combinatie van Slaterdeterminanten kunnen we ook de energie van deze termen uitrekenen, gebruikmakend van de uitdrukkingen voor matrixelementen van één- of tweedeeltjes operatoren tussen twee Slaterdeterminanten. Omdat het vinden van de lineaire combinaties van Slaterdeterminanten bewerkelijk kan zijn brengt de Slater somregel uitkomst. Deze regel maakt gebruik van de eigenschap dat het spoor van een matrix behouden is onder een unitaire transformatie. Dit bespaard ons de moeite om de laatste lineaire combinatie met een orthonomalisatieprocedure te bepalen. Als we eenmaal de energieën hebben blijkt eenvoudig *dat aan de eerste Hund regel is voldaan.* Dit toont dat elektrostatische afstoting tussen valentie elektronen bepalend is voor de grondtoestand.

§ 10.5.3: Dan gaan we naar partieel gevulde schil met twee equivalente d elektronen. Ga na dat er (zonder rekening te houden met het Pauli principe) $(2l+1)(2s+1)\times(2l+1)(2s+1) = 10\times 10 = 100$ mogelijke basistoestanden zijn voor zo'n paar, waarvan er $\binom{10}{2} = 45$ consistent zijn met het Pauli principe. Dit zijn de 45 Slaterdeterminanten uit het bovendeel van Tabel 10.6. Dan zien we in dat die 100 toestanden ook neergeschreven kunnen worden als 100 LS termen in de gekoppelde representatie (onderste deel van Tabel 10.6). De drie vragen komen terug: a.) welke van deze LS termen zijn consistent met het Pauli principe? b.) wat is de relatie tussen de LS termen en de Slaterdeterminanten c.) welke term heeft de laagste energie?

1. a.) Bestudeer de beslissingstabel (Tabel 10.7) waarmee we bepalen welke LS termen consistent zijn met het Pauli principe. Voor drie singletten en twee tripletten blijkt dit het geval te zijn. Volgens de eerste regel van Hund moet één van de twee tripletten ^3F en ^3P de grondtoestand zijn, maar welke?
2. b.) Volledig gestrekte toestanden kunnen geschreven worden als één enkele Slaterdeterminant. Dus kunnen we een uitdrukking neerschrijven voor de Coulombafstoting in de ^3F term, gebruik makend van de Coulomb integralen uit Hoofdstuk 6. Bestudeer hoe de Coulombafstoting in de ^3P term uitgerekend wordt met behulp van de Slater somregel. De afstoting blijkt het kleinst te zijn voor de ^3F term. Dit is de term met de grootste waarde van L. Dit resultaat *bevestigt de tweede regel van Hund.* Dit toont opnieuw dat elektrostatische afstoting tussen valentie elektronen bepalend is voor de grondtoestand.

Parate kennis:

1. Het kunnen neerschrijven van de elektronen configuraties van de grondtoestand van alle elementen t/m Kr.
2. Het kunnen uitleggen van de preferente bezetting van de s schillen en waarom hier anomalieën in optreden bij Cr en Cu.
3. De regels van Hund.
4. Het kunnen neerschrijven van alle termen die behoren bij een gegeven elektronen configuratie.
5. Het kunnen neerschrijven van alle Slaterdeterminanten die behoren bij een gegeven elektronen configuratie en bovendien voldoen aan het Pauli principe (beslissingstabel).
6. Het gebruik van de operatoren $L_\pm$ of $S_\pm$ op LS termen en op Slaterdeterminanten.
7. Het kunnen uitrekenen van de elektrostatische energie van een LS term in termen van Coulomb integralen voor paar toestanden.
8. Het gebruik van de Slater somregel.

10 Ground states of many-electron atoms - deel 2

De derde regel van Hund discrimineert tussen toestanden met dezelfde waarde van L en S maar verschillend in J. Er blijkt verschil tussen *minder* dan halfgevulde schillen en *méér* dan halfgevulde schillen. Om deze regel te kunnen begrijpen gaan we de spin-baan wisselwerking in veel-elektron atomen uitrekenen. We ontdekken dat een *méér* dan halfgevulde schil ook beschouwd kan worden als een volle schil waaraan een aantal *gaten* zijn toegevoegd. Zo'n gat heeft een positieve lading en daarom draait het teken van de spin-baan koppelingssterkte om, *i.e.*, $\xi(r)$ wordt negatief (zie sectie 4.6.1). Dit heeft als gevolg dat ook de niveauverschuivingen van teken wisselen. Voor gegeven waarde waarde van L en S verandert daarom de J toestand met *hoogste energie* voor *minder* dan halfgevulde schil in de J toestand met *laagste energie* voor *meer* dan halfgevulde schil. Nu we de drie regels van Hund begrijpen kunnen we voor ieder atoom met LS koppeling en gegeven *elektronen configuratie* de grondtoestand uitrekenen.

§ 10.6: Veel-elektron atomen met fijnstructuur - derde regel van Hund.

§ 10.6.1: Bestudeer hoe de Zeeman hamiltoniaan voor een systeem van N elektronen met baanimpulsmoment $\boldsymbol{l}_i$ en spin $\boldsymbol{s}_i$, waarbij $i \in \{1, \cdots N\}$, herschreven kan worden als een effectieve Zeeman hamiltoniaan van één deeltje met baanimpulsmoment $\mathbf{L} = \sum_i \boldsymbol{l}_i$ en spin $\mathbf{S} = \sum_i \boldsymbol{s}_i$.

§ 10.6.2: In deze paragraaf zien we dat we de spin-baankoppeling van één elektron kunnen uitrekenen zoals in het geval van waterstof maar dan met de Coulomb potentiaal vervangen door een afgeschermde Coulomb potentiaal. Ga na dat de koppelingsconstante zal toenemen met de kernlading.

§ 10.6.3: Dan buigen we ons over de koppeling tussen de impulsmomenten van de verschillende elektronen. Zolang de exchange domineert over de spin-baan koppeling (dit is het geval voor atomen met niet te grote kernlading) koppelen eerst de baan-impulsmomenten tot een totaal baan-impulsmoment $\mathbf{L} = \sum_i \boldsymbol{l}_i$ en de spin-impulsmomenten tot een totale spin $\mathbf{S} = \sum_i \boldsymbol{s}_i$. Daarna pas koppelen $\mathbf{L}$ en $\mathbf{S}$ tot het totaal impulsmoment $\mathbf{J} = \mathbf{L} + \mathbf{S}$. Deze $\mathbf{J}$ is de behouden grootheid in nulveld (onder verwaarlozing van hyperfijnstructuur). Deze vorm van koppeling wordt LS koppeling of Russell-Saunders koppeling genoemd. Bij atomen met zeer grote kernlading domineert de spin-baan koppeling over de exchange en koppelen eerst de $\boldsymbol{l}_i$ en $\boldsymbol{s}_i$ tot $\boldsymbol{j}_i$. Daarna koppelen de $\boldsymbol{j}_i$ tot het totaal impulsmoment $\mathbf{J} = \boldsymbol{j}_1 + \cdots \boldsymbol{j}_N$, de behouden grootheid. Deze vorm van koppeling wordt jj koppeling genoemd.

§ 10.6.4: In het college beperken we ons tot LS koppeling omdat dit van toepassing is op de meest courante elementen uit het periodiek systeem. Het blijkt dat ook de spin-baan hamiltoniaan herschreven kan worden als een effectieve spin-baan hamiltoniaan van één deeltje met baanimpulsmoment $\mathbf{L} = \sum_i \boldsymbol{l}_i$ en spin $\mathbf{S} = \sum_i \boldsymbol{s}_i$. Bestudeer hoe dit resultaat verkregen wordt met behulp van het Wigner-Eckart theorema.

Met dit alles is de hamiltoniaan van een veel-elektron systeem gereduceerd tot een ééndeeltjes hamiltoniaan. Als gevolg hiervan is de fenomenologie van veel-elektron atomen in vele opzichten gelijk aan die van waterstofachtige atomen, met dien verstande dat de spin S niet noodzakelijkerwijs gelijk is aan $1/2$ maar een willekeurige waarde kan aannemen.

§ 10.6.5: Bestudeer dat een elektronenschil met een vacature zich gedraagt als een volle schil waar een gat aan is toegevoegd. Zo'n gat denkt een elektron af zodat er een vacature ontstaat en heeft daarom een negatieve massa, een positieve lading en een intrinsiek magnetische moment tegengesteld aan dat van het elektron. Elektron en gat bevinden zich altijd op dezelfde plaats en hebben dezelfde snelheid maar hun baanimpuls is tegengesteld. Bestudeer hoe we met een optel/aftrek procedure kunnen laten zien dat de spin-baan koppelingsconstante ζ_{nl} van een gat (i.e., een schil met één vacature) negatief is.

§ 10.6.6: Wat resteert is het uitrekenen van het matrixelement van de spin-baan koppeling (de spin-baan verschuiving) voor de volledig gestrekte toestand (maximale **L** en maximale **S**) die volgt uit de Hund regels 1 en 2 voor een willekeurige nl^x configuratie. Omdat deze toestand geschreven kan worden als één Slaterdeterminant kunnen we dit doen op twee manieren. Eerst sommeren we de één-elektron bijdragen, die we met Eq. (9.44) kunnen schrijven als som over de bijdragen van de één-elektron toestanden. Het gaat hier immers over de diagonaal matrixelementen van een één-deeltjes operator, $\sum_i \xi_i \boldsymbol{l}_i \cdot \boldsymbol{s}_i$. Dit levert uitdrukking (10.131) die evenredig is met de één-elektron koppelingsconstante ζ_{nl}.
Dan vergelijken we dit resultaat met de uitdrukking verkregen met de effectieve hamiltoniaan, die evenredig is met ζ_{nLS}. Het resultaat van deze vergelijking blijkt af te hangen van de vulling van de schil. Voor een minder dan halfgevulde schil vinden we voor de veel-elektron koppelingsconstante $\zeta_{nLS} = \zeta_{nl}/2S$; voor een méér dan halfgevulde schil vinden we $\zeta_{nLS} = -\zeta_{nl}/2S$. Merk op dat de noemer $2S$ opgevat kan worden als het aantal *elektronen* in een *minder* dan halfgevulde schil, dan wel het aantal *gaten* in een *méér* dan halfgevulde schil. Begrijp hoe je aan de fijnstructuur kunt zien of een schil minder of méér dan half gevuld is (zie ook Fig. 10.9). Begrijp verder dat de Hund regel 3 geen rol speelt bij een halfgevulde schil omdat daar J slechts één waarde kan aannemen ($J = S$).
Dit voltooit de onderbouwing van de *derde Hund regel.* Hier blijkt de spin-baan koppeling doorslaggevend.

§ 10.8: Deze sectie over jj koppeling valt *buiten* de tentamenstof.

Parate kennis:

1. De regels van Hund
2. De equivalentie van elektronen en gaten, i.h.b. de eigenschappen van de gaten: negatieve massa, positieve lading en een intrinsiek magnetische moment tegengesteld aan dat van een elektron, snelheid gelijk aan de snelheid van het elektron dat het gat kan vullen maar met tegengesteld impuls.
3. Het kunnen neerschrijven van de Slaterdeterminant van de volledig gestrekte toestand die verkregen wordt door toepassing van de Hund regels 1 en 2.
4. De uitdrukking voor de spin-baan verschuiving
$$\Delta E_{n,J}^{LS} = \left(\zeta_{nLS}/\hbar^2\right) \langle nLSJM_J|\mathbf{L}\cdot\mathbf{S}|nLSJM_J\rangle.$$
5. De relaties voor de derde regel van Hund
$$\zeta_{nLS} = +\frac{\zeta_{nl}}{2S} \text{ for } 0 < x < 2l+1$$
$$\zeta_{nLS} = -\frac{\zeta_{nl}}{2S} \text{ for } 2l+1 < x < 2(2l+1)$$
voor de spin-baan koppelingsconstanten van een minder dan halfgevulde schil, $0 < x < 2l+1$, of een méér dan halfgevulde schil, $2l+1 < x < 2(2l+1)$.
6. Het kunnen bepalen van de grondtoestand van een willekeurig atoom op basis van een gegeven elektron configuratie.

H Time-independent perturbation theory (facultatief)

De appendix over storingsrekening is facultatief. Het is een inhaalcollege, bedoeld voor studenten die niet eerder met storingsrekening hebben kennisgemaakt. Het onderwerp is helaas gortdroog maar essentieel voor het begrijpen van de rest van het college. We maken kennis met een „storende term” in de hamiltoniaan. Bij een niet-ontaarde toestand verschuiven alleen de energieniveaus; bij een ontaarde toestand kan de storingsterm de symmetrie breken met als gevolg niveausplitsing. We leren dat als de storing commuteert met de hamiltoniaan, de storingsrekening voor een ontaard niveau reduceert tot „gewone” storingsrekening; i.e., storingsrekening van een niet-ontaard niveau.

Thuis bestuderen:

Appendix H tot aan bespreking van de derde orde correctie en het begrip renormalisatie van de golffunctie. Deze onderwerpen zijn belangrijk voor de verdieping van de stof maar zijn facultatief.

§ H.1: In deze inleidende paragraaf maken we kennis met de begrippen *ongestoorde hamiltoniaan* $\mathcal{H}_0$ en *storing* $\mathcal{H}_1$. We definiëren representaties $\{|\psi_n\rangle\}$ van de volledige hamiltoniaan $\mathcal{H} = \mathcal{H}_0 + \mathcal{H}_1$ en $\{|\phi_n\rangle\}$ van de ongestoorde hamiltoniaan $\mathcal{H}_0$ en leiden een uitdrukking af voor de niveauverschuiving als gevolg van de storing $\mathcal{H}_1$.

§ H.2: *Storingsrekening van een niet-ontaard niveau.* We parametriseren de hamiltoniaan door het invoeren van de storingsparameter λ. We introduceren de gestoorde toestanden $|\psi_n(\lambda)\rangle$ met bijbehorende storingscoëfficiënten $a_n(\lambda)$. In de *Ansatz* schrijven we de gestoorde toestand $|\psi_n(\lambda)\rangle$ als een ontwikkeling in machten λ^p waarbij de coëfficiënten $|\psi_n^p\rangle$ (met bijbehorende coëfficiënten a_n^p) een nader te bepalen correctie vormen op de ongestoorde toestand $|\psi_n^0\rangle \equiv |\phi_n\rangle$. We schrijven een uitdrukking voor de normering van de gestoorde toestanden. Het blijkt dat de toestanden alleen genormeerd blijven als de coëfficiënten a_n^p aan bepaalde eisen voldoen. We leiden vervolgens een uitdrukking af voor de niveauverschuiving in de vorm van een ontwikkeling in machten van λ. Zo krijgen wij bijdragen aan de niveauverschuiving schrijven in orden van λ.

1. *nulde orde.* Dit is de energie van de ongestoorde toestand.
2. *eerste orde.* De correctie *van de energie* in eerste orde wordt verkregen door de storing te “sandwichen” tussen de ongestoorde toestanden. Met het resultaat kan de eerste orde correctie *van de toestand* worden uitgerekend.
3. *tweede orde.* De tweede orde correctie *van de energie* wordt verkregen door de eerste orde correctie *van de toestand* in rekening te brengen. Ook kunnen we dan de tweede/orde correctie *van de toestand* bepalen. Bij een niet ontaard niveau (*gewone storingsrekening*) hoef je alleen de 1e- en 2e-orde verschuivingen van de energie te kunnen uitrekenen.

§ H.3: *Storingsrekening van een ontaard niveau.* We beginnen op dezelfde manier als voor niet-ontaarde niveaus maar het blijkt onmiddellijk bij het neerschrijven van de *Ansatz* dat dit niet meer op unieke wijze valt te doen. We hebben *voorkennis* nodig van het effect van de storing om de Ansatz zó te kunnen doen dat de storingscoëfficiënten zich als reguliere functies van λ gedragen. Met andere woorden: we moeten rekening houden met het breken van de symmetrie door de storing. Als we dat doen dan vinden wij uitdrukkingen voor de eerste en tweede orde verschuivingen die analoog zijn aan die van de gewone storingsrekening (i.e., de storingsrekening van een niet-ontaard niveau.

1. In het algemeen is het niet onmiddellijk duidelijk hoe de storing de symmetrie zal gaan breken. Daarom is het belangrijk om te weten dat uitgaande van een willekeurige ongestoorde basis de energieverschuivingen ε van de ongestoorde toestanden worden verkregen door een stelsel van gekoppelde vergelijkingen op te lossen. Dit is equivalent met het nul

stellen van de zogenaamde *seculierdeterminant.* We krijgen dan voor een stelsel van k vergelijkingen een polynoom van orde k in de variabele ε (het zgn. *karakteristieke polynoom* van het stelsel vergelijkingen - ook wel de *seculiervergelijking* genoemd). De wortels van dit polynoom zijn de eigenwaarden voor de enegieverschuivingen. De bijbehorende eigentoestanden reflecteren de symmetrie van de storing. Het stelsel van gekoppelde vergelijkingen kan geschreven worden als matrix vergelijking. Het oplossen van dit stelsel is equivalent met het diagonaliseren van de matrix (de zgn. storingsmatrix).

§ H.3.1: Deze sectie is van groot praktisch belang. In het speciale geval dat de storing commuteert met de ongestoorde hamiltoniaan bestaat er een basis waarin is de storingsmatrix diagonaal is. In die basis kan men de storing eenvoudig exact uitrekenen omdat de exacte oplossing gelijk is aan de eerste orde uitdrukking van „gewone” storingsrekening. Vaak echter commuteren de hamiltonianen slechts in benadering. Dan is de storingsmatrix ook slechts in benadering diagonaal maar blijft de eerste orde benadering van gewone storingsrekening afdoende voor het uitrekenen van de niveauverschuivingen. Expliciet diagonaliseren is dan niet nodig en zegt men dat de storingsrekening voor een ontaard niveau reduceert tot „gewone” storingsrekening.

§ H.4: *Voorbeeld: tweedimensionale storingsmatrix.* Begrijp de definitie van de koppelingshoek en het verschil tussen een *zwakke* koppeling en een *sterke* koppeling tussen de niveaus. Merk op dat de koppeling tussen twee niveaus aanleiding geeft tot *afstoting* tussen die niveaus. Begrijp ook dat bij zwakke koppeling de afdiagonale matrixelementen verwaarloosd mogen worden t.o.v. de diagonale elementen (deze dragen dan bij in tweede orde).

§ G.3.4: Hier wordt het verschil tussen zwakke en sterke koppeling samengevat.

Parate kennis:

1. Bij tijdonafhankelijke storingsrekening de opsplitsing van de hamiltoniaan in twee hermitsche delen
$$\mathcal{H} = \mathcal{H}_0 + \mathcal{H}_1 .$$
2. Bij „gewone” storingsrekening: de formule voor de eerste orde energieverschuiving
$$\varepsilon_1 = \langle \phi_n | \mathcal{H}_1 | \phi_n \rangle .$$
met $\{|\phi_n\rangle\}$een orthonormale set behorend bij $\mathcal{H}_0 |\phi_n\rangle = E^0 |\phi_n\rangle$.
3. Bij „gewone” storingsrekening: de formule voor de tweede-orde energieverschuiving
$$\varepsilon_2 = \langle \phi_n | \mathcal{H}_1 |1\rangle = \sum_{\substack{m \\ m\neq n}} \frac{|\langle \phi_n | \mathcal{H}_1 | \phi_m \rangle|^2}{E_n^0 - E_m^0} .$$
4. Bij storingsrekening voor een ontaard niveau moeten we de seculiervergelijking oplossen,
$$\det \left| \mathcal{H}'_{i,j} - \varepsilon_1 \delta_{i,j} \right| = 0,$$
waarin $\mathcal{H}'_{i,j} = \langle \phi_{n,i} | \mathcal{H}_1 | \phi_{n,j} \rangle$ met $\{|\phi_{n,i}\rangle\}$ de basis behorend bij $\mathcal{H}_0 |\phi_{n,i}\rangle = E^0 |\phi_{n,i}\rangle$.
5. In de *zwakke koppelingslimiet*, geven de diagonaalelementen van de storingsmatrix $\mathcal{H}'_{i,j}$ een bijdrage in eerste orde en de afdiagonaal elementen een bijdrage in tweede orde (en kunnen dus verwaarloosd worden in een „eerste orde berekening”). Dit geldt bijvoorbeeld voor de Paschen-Back limiet van de fijnstructuur en hyperfijnstructuur.
6. Realiseer je dat als $\mathcal{H}_0$ en $\mathcal{H}_1$ commuteren met $\mathcal{H}$ de seculierdeterminant diagonaal is en daarmee de storingsrekening reduceert tot „gewone” eerste orde storingrekening.

Reader

1 Quantum motion in a central potential field

The first chapter is about the Schrödinger equation for a particle in a central potential field. The major part will be a repetition of material known from elementary lectures in mathematics, classical mechanics and quantum mechanics. Our task is to formulate the Schrödinger equation for this problem and reduce it by separation of variables into a 1D equation for the radial motion (the radial wave equation) plus two eigenvalue equations for the rotational motion about the potential center. Only the radial wave equation depends on the central potential; the equations for the rotational motion are the same for all systems of central symmetry. The rotational eigenvalues are represented by the quantum numbers l and m. The associated eigenfunctions are the spherical harmonics. The lecture is concluded by a brief discussion of the invariance of the Hamiltonian under rotation in relation to the angular momentum as a conserved quantity.

Study at home:

Chapter 1: Read the introduction. Note the definition of a central potential $\mathcal{V}(r)$ between two bodies, where $r = |\mathbf{r}_1 - \mathbf{r}_2|$ is the radial distance and m_r the reduced mass. In the first chapter your primary task is preserve the overview. It may be a good idea to refresh your memory about Quantum Mechanics. Appendix F may be helpful in this respect. Problem F.1 is very important. Problems 1.2, 1.3, 1.6 and 1.7 are included to deepen your understanding of some mathematics, don't waist too much time on this - certainly not before you have captured the overview over the chapter. Also the discussion of *cylindrical coordinates* are optional (i.e., not part of the exam).

§ 1.1: We introduce the notions *radial momentum*, p_r, and *angular momentum* with respect to the potential center, $\mathbf{L}$. Study the *classical Hamiltonian* H_0 and its separation into *radial* and *rotational* kinetic energy. Recall the *Einstein notation* with the *summation convention* and solve Problem 1.1.

§ 1.1.1: Here we introduce *operators* for position and momentum (*correspondence rules*) in the *position representation*; derivation of the *commutation relations in cartesian coordinates* (using a test function ϕ); beware of potential difficulties in the application of the correspondence rules in *products of non-commuting operators*. Understand how the central symmetry is exploited by introducing *spherical coordinates*. An expression of great importance is the laplacian in *spherical coordinates*. The discussion of *cylindrical coordinates* is optional.

§§ 1.1.2: Here we derive the operators for *orbital angular momentum* $\mathbf{L}$ (in the position representation using orthogonal coordinates, *cartesian* or *curvilinear*). In particular, take notice of the expression for $\mathbf{L}$ in *spherical coordinates*, an example of (orthogonal) curvilinear coordinates.

§ 1.1.3: Solve the *eigenvalue equation* for L_z.

§ 1.1.4: Understand the usefulness of *commutator algebra*. This enables us to derive the commutation relations for L_x, L_y, L_z and $\mathbf{L}^2$ *without* the use of a test function. Problem 1.4 is very instructive.

§ 1.1.5: Same for $L_\pm$. Reformulation of $\mathbf{L}^2$ in terms of L_+, L_- and L_z.

§ 1.1.6: Solve the eigenvalue expression for $\mathbf{L}^2$ (using the principle of *separation of variables*). The details of the $P_l^m(u)$ are optional. It is important to understand the action of $L_\pm$ as a shift operator but the detailed consequences for the spherical harmonics are optional. However, you should know that the choice of the positive sign in front of the square root formula corresponds to the *Condon and Shortley phase convention.* This convention assures the proper operation of the shift operators as construction operators for both positive and negative values of the quantum number m.

- § 1.1.7: Understand the use and importance of angular momentum in the *representation-free* notation of *Dirac.*
- § 1.1.8: Understand the derivation of the expression for the radial momentum p_r and the commutation relations for p_r and p_r^2. Problem 1.5 is optional but Problem 1.6 is very useful (for 2D optional).

§ 1.2: Schrödinger equation

- § 1.2.1: Here we formulate the *3D Schrödinger equation* for the wavefunction $\psi_{lm}(r)$ of a particle in a central potential field using spherical coordinates. Reduction of the 3D Schrödinger equation to the 1D *radial wave equation* for the radial wavefunction $R_l(r)$ of given angular momentum l, plus the 2D Schrödinger equation for the wavefunction $Y_{lm}(\hat{\mathbf{r}})$, with $\hat{\mathbf{r}} \equiv (\theta, \phi)$, which describes the rotational motion about the potential center. Understand the *separation of variables* and the reduction of the radial wave equation to the form of a *1D Schrödinger equation* by introducing a so called *reduced radial wavefunction* $\chi_l(r) = rR_l(r)$. Problems 1.7-1.9 are optional.
- § 1.2.2: Same for cylindrical coordinates. This section is optional.

§ 1.3: Read this section carefully. Understand the concept of parity. Understand that commutation of the operators $\partial/\partial\phi$ and $\mathcal{H}_0$ implies the invariance of $\mathcal{H}_0$ under rotation about the z axis.

Minimum knowledge:

1. The name and definition of the quantities m_r, p_r, $\mathbf{L}$, $L_\pm$, $\mathcal{V}_{\text{rot}}(r)$, l, m, $\chi_l(r)$.
2. The expression for the linear momentum operator, $p_i = i\hbar\partial_i$ and the derivation of $[r_i, p_j] = i\hbar\delta_{ij}$ using a test function.
3. The commutation relations for L_x, L_y and L_z and their derivation using commutator algebra; i.e., *without* the use of a test function.
4. The inner product rule $\mathbf{L}^2 = \mathbf{L} \cdot \mathbf{L} = L_zL_z + \frac{1}{2}(L_+L_- + L_-L_+)$ with $L_\pm = L_x \pm iL_y$.
5. The principle of separation of variables in relation to commuting operators.
6. Understand why the radial wavefunction has to be regular in the origin and why this is always the case for the radial wavefunctions of electrons in a real atom.
7. The following expressions for the Hamiltonian
$$H_0 = \frac{\mathbf{p}^2}{2m_r} + \mathcal{V}(r) \quad \text{and} \quad H_0 = \frac{1}{2m_r}\left(p_r^2 + \frac{\mathbf{L}^2}{r^2}\right) + \mathcal{V}(r) \quad (r \neq 0).$$
8. The expression for the quantum mechanical Hamiltonian
$$\mathcal{H}_0 = -\frac{\hbar^2}{2m_r}\Delta + \mathcal{V}(r).$$
9. The eigenvalue equation for L_z and $\mathbf{L}^2$ in the Dirac notation
$$\mathbf{L}^2 |l, m\rangle = l(l+1)\hbar^2 |l, m\rangle$$
$$L_z |l, m\rangle = m\hbar |l, m\rangle$$
and the action of the *shift operators*
$$L_\pm |l, m\rangle = \sqrt{l\,(l+1) - m(m \pm 1)}\,\hbar\,|l, m \pm 1\rangle\,,$$
where the choice for the *positive* square root defines the *Condon and Shortley phase convention.*

10. The radial wave equation

$$\left[\frac{\hbar^2}{2m_r}\left(-\frac{d^2}{dr^2}-\frac{2}{r}\frac{d}{dr}+\frac{l(l+1)}{r^2}\right)+\mathcal{V}(r)\right]R_l(r)=ER_l(r).$$

11. The definition $\chi_l(r) \equiv rR_l(r)$ and the derivation of the 1D Schrödinger equation starting from the radial wave equation,

$$\chi_l'' + \left[\frac{2m_r}{\hbar^2}\left(E-V\right)-\frac{l(l+1)}{r^2}\right]\chi_l = 0.$$

2 Hydrogenic atoms

The second chapter is about solving the Schrödinger equation for an electron in the central potential field (Coulomb field) of the atomic nucleus. This is called the "Bohr atom". The rotational states are already known from Chapter 1 (spherical harmonics). Hence, what remains to be done is solving the radial wave equation. We introduce atomic units and learn how quantization follows from the normalization requirement of the wavefunction. This procedure results in the discrete energy levels of the hydrogen atom (the so-called hydrogen *Term* energies) and the related hydrogenic wavefunctions. Further you learn how to calculate the diagonal and off-diagonal matrix-elements of the electric dipole operator using hydrogenic wavefunctions.

Study at home:

Chapter 2: Read the introduction about "one-electron atoms" and take notice of what is meant by *hydrogen like* (*hydrogenic* or *alkali-like*). The challenge is to keep the overview. Problems 2.1, 2.2, as well as 2.4 and 2.5 are quite useful. Problem 2.3 is for highly motivated enthusiasts of special functions; Problem 2.6 is for those who want to practice their Mathematica skills. In first reading you can skip these problems altogether.

§ 2.1: Here we formulate the radial Schrödinger equation for the case of the hydrogen atom; i.e., using the *Coulomb* interaction between electron and nucleus. Make yourself familiar with the notions s wave, p wave, *etc.*, and the use of the name *orbital* for the orbital wavefunction. Take notice of the notation R_{nl} and the alternatives $R_{10} \equiv R_{1s}$ for the case $n, l = 1, 0$.

§ 2.1.1: The introduction of *atomic units* and the appearance of the *fine structure constant* α. Take notice of the difference between the Hartree and the Rydberg energy. Solve Problem 2.1.

§ 2.1.2: Study the limiting behavior of the wavefunctions for $r \to 0$ and $r \to \infty$ and the appearance of the *quantization condition* from the normalization condition on the wavefunction. Note how the *principal quantum number* enters the theory.

§ 2.2: The *Bohr formula* for the hydrogen *level structure* (*Term diagram*) and the *Rydberg formula,*

$$E_n = -hcR_M \frac{Z^2}{n^2} \quad \Leftrightarrow \quad \frac{1}{\lambda_n} = -R_M \left[\left(\frac{1}{n}\right)^2 - \left(\frac{1}{n_0}\right)^2 \right], \text{ with } n > n_0.$$

Further the n^2 *degeneracy* of the energy levels and its relation to the rotational wavefunctions (spherical harmonics). Understand the difference between essential and accidental degeneracy.

§ 2.3: The general expression for the hydrogenic wavefunctions for the radial motion $R_{nl}(\rho)$ and the associated normalization factor $\mathcal{N}$. Take notice of the plots of the radial wavefunctions, in particular the systematics of the number of nodes.

§ 2.3.1: Familiarize yourself with the *Dirac notation* for the eigenstates of the orbital motion, $|nlm\rangle$, and the relation with the wavefunctions in the position representation (with spherical coordinates).

§ 2.4: Diagonal matrix elements.

§ 2.4.1: Here we learn how to calculate *radial averages* (exact solutions exist but they can become complicated - take notice of Eq. (2.48) *but do not your waist time* on the proof of Problem 2.3, which is included for the enthusiasts of special functions). It is better to focus on Problem 2.2 because it shines light on the origin of the Wigner-Eckart theorem.

§ 2.4.2: The *integral over three spherical harmonics* (Gaunt integral) is the *Rosetta stone* for the calculation of angular averages, see Eq. (2.54) and the role of $3j$ symbols. Practice this type of integral by solving Problems 2.4 en 2.5. An introduction in $3j$ symbols is given in § 3.4.6 (cf. Appendix J).

§ **2.5:** Off-diagonal matrix elements.

§ 2.5.1: Take notice of the definition of the *electric dipole operator*

$$\mathbf{d} = -\,e\mathbf{r} = -\,ea\rho\,\hat{\mathbf{r}}$$

and the calculation of *transition matrix elements = off-diagonal matrix elements* and the notion of *transition-dipole* moment. The transition dipole determines the selection rules for *electric-dipole transitions.* These are of great practical importance because they represent the strongest interaction of atoms with light. In practice a transition is allowed if the corresponding $3j$ symbol is nonzero.

§ 2.5.2: The unit vector in radial direction $\hat{\mathbf{r}}$ and its decomposition to the spherical basis; angular matrix elements.

§ 2.5.3: Here we derive expressions for the *transition dipole* and define the *transition strength.*

§ 2.5.4: Selection rules for electric-dipole transitions; the photon and the photon spin. Understand the difference between σ_+, σ_- and π transitions (see Fig. 2.4). The derivations are not part of the exam.

§ 2.5.5: Study how we calculate the Lyman series and the Balmer series. Note that the sum of the transition probabilities is the same for all upper (or lower) levels of a given manifold (see Fig. 2.5). Problem 2.6 is a key problem, essential for future understanding of the coupling of electrons to the electromagnetic field. You can practice your Mathematica skills by evaluating the integrals.

Minimum knowledge:

1. The notions *hydrogen like* (*hydrogenic* or *alkali-like*), s wave, p wave, etc..

2. The *atomic units* of length (a) and energy (Hartree $\hbar^2/m_r a^2$) and what they correspond to in the atom.

3. The relation between the *Hartree* and the *Rydberg* atomic units: $E_H = 2E_R$.

4. The relation between the *Rydberg constant* R_M and the *Rydberg energy*: $E_R = hcR_M$.

5. The relation between the Hartree atomic unit, electron rest energy and fine structure constant:

$$\hbar^2/m_r a^2 = \alpha^2 m_r c.$$

6. The energy levels (*Terms*) of hydrogenic atoms and the notion *Term diagram*,

$$E = -(\alpha^2 m_r c^2) Z^2/2n^2,$$

as well as the *Rydberg formula*

$$\lambda_n^{-1} = -R_M\left[(1/n)^2 - (1/n_0)^2\right] \quad \Leftrightarrow \quad \Delta E_n = E_n - E_{n_0} = hc/\lambda_n, \text{ with } n > n_0.$$

7. The energy splittings of the *principal* structure are typically a factor α^2 smaller than the electron *rest mass energy.*

8. The derivation of the relation for *radial average*

$$\langle \rho^k \rangle \equiv \langle nlm|\rho^k|nlm\rangle = \int \rho^{k+2}\tilde{R}_{nl}^2(\rho)d\rho,$$

where

$$\int \tilde{R}_{nl}^2(\rho)\rho^2 d\rho = 1.$$

9. The definition of the *electric-dipole operator*,

$$\mathbf{d} = -\,e\mathbf{r} = -\,ea\rho\,\hat{\mathbf{r}}.$$

10. Make sure that you can determine when $3j$ symbols are nonzero and apply the $3j$ symbol rules (the triangular inequalities, the $3m$ sum rule, the m inversion rule, and the permutation rules). For a discussion of the $3j$ symbols see also § 3.2.2 and Appendix J.

3 Angular momentum

The third chapter starts with a surprise: after all the work in Chapter 1 it turns out that we can obtain the eigenvalues of $\mathbf{L}^2$ and L_z and the properties of L_+ and L_- also *without* solving the Schrödinger equation. All we need are the commutation relations for L_x, L_y and L_z. Starting from these relations we can derive an algebra which reproduces the properties of the orbital angular momentum operators. This is done with the representation-free notation of Dirac (a notation without "wavefunctions"). We generalize this approach by arguing that *any* observable satisfying the same commutation relations as L_x, L_y and L_z must also satisfy the same algebra; i.e., have the properties of quantized angular momentum. Importantly, also half-integral values turn out to be consistent with this algebra (with the electron spin, $s = 1/2$, as the famous example). Of crucial importance is further the addition of angular momenta. In this context we introduce the *coupled* and the *uncoupled* representation as well as the Clebsch-Gordan transformation between these. The vector-coupling model is an important tool in this context, in particular for reading $3j$ symbols.

In the second part of the chapter we investigate how the angular momentum *operators* and the angular momentum *states* transform under rotation of the quantization axis. This is called representation theory. It leads to the conclusion that the angular momentum operators can be identified with operators imposing an infinitesimal rotation on the physical system.

Study at home:

Beware: Chapter 3 is rather formal and quite demanding. It is important because quantized angular momentum plays a major role in quantum physics and certainly in Atomic Physics (if only because the total angular momentum of a free atom is conserved in time). It is essential for a proper understanding of optical transitions in atoms. The chapter is of special interest for students geared towards theoretical physics. The following is part of the course, while the optional material is described afterwards.

§ 3.1: This is an important section for all. Here we find that all properties of angular momentum in quantum mechanics follow from an *algebra* derived from the *commutation relations* for J_x, J_y en J_z. The derivation is instructive but is not required for the exam. *All students* should be able to reproduce the summary (3.1.0.1). Importantly, aside from integral angular momenta, $j = 0, 1, 2, \cdots$, also half-integer angular momenta, $j = \frac{1}{2}, \frac{3}{2}, \frac{5}{2}, \cdots$, are allowed. In § 3.9.3 we shall find that the latter have *no classical analog.*

> § 3.1.1: We discuss the decomposition of the angular momentum vector $\mathbf{J}$ in the *cartesian basis* as well as the *spherical basis*. Note the subtle difference between the *standard components* J_0, J_{+1} and J_{-1} and the *shift operators* J_z, J_+ and J_-.

§ 3.2: Starting from the eigenvalues we can construct the matrix representation that satisfies all properties mentioned in § 3.4. Study how this works for $l = 1$ in the spherical and cartesian basis. Convince yourself that the Pauli matrices are obtained for $s = 1/2$. Problem 3.1 is optional.

§ 3.3: In the general part of this section we summarize the difference between angular momentum in classical physics and in quantum mechanics. Note how the *polarization vector* in quantum mechanics replaces the *angular momentum vector* from classical mechanics. The *vector model* of Fig 3.1 helps to visualize the angular momentum vector $\mathbf{J}$ (which is not observable) and its projections on a quantization axis (which are observable). Note Problem 3.2.

> § 3.3.1: In this section we discuss how the polarization of the angular momentum can be measured. Make sure that you understand the difference between a *pure ensemble* and a *random ensemble* and digest the notion *degree of polarization.* In an *optional* part we discuss how the polarization can be determined within the density matrix formalism.

§ 3.3.2: In this section we calculate the polarization for a pure ensemble of a $s = 1/2$ system (also known as a qubit). We show that the polarization of an arbitrary state can be represented by a point on the *Bloch sphere*. This makes the Bloch sphere into the geometrical representation of all possible states of a qubit. This is a nice bit of quantum mechanics which plays an important role in modern atomic physics and in quantum information processing. Make sure that you understand the Bloch sphere (see Fig. G.1). Beware of the difference between the components of the angular momentum (which is a vector in the 3D space of the laboratory) and the components of the qubit (which is a vector in a 2D complex vector space - the Hilbert space of the qubit). In other words, do not confuse a vector in the lab with a state of the qubit.

§ 3.3.3: An alternative method to describe a spin system is the density matrix formalism (cf. Appendix F.3). This method is more general than the methods developed for pure states because it can also be used with the statistical mixtures mentioned in the introduction to Section 3.3. Familiarize yourself with the density operator and its matrix representation and study how these are used to calculate the polarization for a pure ensemble. Work through this section and convince yourself of Eq. (3.74).

§ 3.4: This section is of central importance *for the proper understanding of the whole course.*

§ 3.4.1: We first introduce the Hilbert space for a system of two angular momenta, $\boldsymbol{j}_1$ en $\boldsymbol{j}_2$. We define the *uncoupled basis* as the basis formed by the tensor product of the bases of the individual angular momenta. Please note that the tensor product is an ordered product. Usually little attention is paid to this because it does not have serious consequences as long as we limit ourselves to two angular momenta. For coupling of more than two this is different. We return to this in detail in Section 3.5. You may forget about many details but make sure you know the difference between stretched and non-stretched states - see Example 3.1 en 3.4.2.

§ 3.4.2: We learn how to add two angular momentum operators, keeping in mind the *triangle inequalities*. In this way we obtain the *coupled basis* of the Hilbert space. Convince yourself that the coupled and the uncoupled representation are of thee same dimension (see Problem 3.4) because they span the same Hilbert space. The addition of angular momenta will be used over and over again in the coming chapters. Study the geometrical addition as illustrated in Fig. 3.4. (called the *vector coupling model*) and solve Problem 3.3. Make sure that you understand the difference between the *coupled* and the *uncoupled* representations of a given angular momentum subspace.

§ 3.4.6: Here we learn the about the so-called *Clebsch-Gordan transformations* between the coupled and the uncoupled representations. These transformations follow straightforwardly from the closure relations for these representations. The Clebsch-Gordan coefficients are proportional to $3j$ symbols. For the latter we can rapidly establish if they vanish or not. In the latter case we can look up the value in Appendix J (or by using Mathematica). The symmetry rules are very important. These are given in Appendix J.1. It is a good idea to memorize them. Memorization is not very popular among scientists but you will not regret it. The coupled representation is related to the uncoupled representation by a unitary transformation. Convince yourself by making Problem 3.5.

§ 3.6: In this section we introduce the *coupling of angular momenta*. First of all it is important to realize that the coupled and uncoupled representations are defined irrespective of the presence of absence of a coupling mechanism. If $\boldsymbol{j}_1$ and $\boldsymbol{j}_2$ are conserved quantities, also their vector sum, $\mathbf{J} = \boldsymbol{j}_1 + \boldsymbol{j}_2$, will be a conserved quantity. This can change as soon as $\boldsymbol{j}_1$ and $\boldsymbol{j}_2$ are coupled to something (e.g., each other). We distinguish between *internal* and *external* coupling. In both cases $\boldsymbol{j}_1$ and $\boldsymbol{j}_2$ are no longer conserved. In case of *internal* coupling **J** remains conserved because the system remains mechanically closed. In the case of external coupling also **J** is no longer conserved. In important cases both internal and external couplings cam be present. Make sure that you understand what is meant by *coupling of the J levels* - see also Section 3.4.5. The *inner product rules* are indispensable throughout the course (see Problem 3.6).

§ 3.7: Read this section and be familiar with the concept of the $6j$ symbol and that they are defined in terms of $3j$ symbols.

§ 3.8: We now turn to representation theory, the theory that tells us what happens in Hilbert space if we rotate a physical system in reals space. It is an interesting section but also difficult. Before you start reading this section make sure that you have enough time.

§ 3.8.1: We study in detail how the operators and the states of a $s = 1/2$ system transform under a pure rotation of the quantization axis. Understand what is meant by a *pure* rotation.

§ 3.8.2: It turns out that an *arbitrary* pure rotation of the quantization axis can be realized with three subsequent rotations over the so-called *Euler angles* α, β, and γ. First we demonstrate this for a co-rotating coordinate system (as experienced by a pilot in the cockpit of an airplane). Fig. 3.7-b is important in this context. Next we show that the same rotation can also be realized in the laboratory-fixed frame by three subsequent rotations (about the z axis, the y axis and again the z axis) over the *same* Euler angles (but in *reversed* order). In real space the rotation operators take the form of 3×3 matrices. For the exam it is not required that you can reproduce the derivation but you should know the expressions for a general pure rotation over the Euler angles as given by Eqs. (3.183) and (3.187).

§ 3.8.3: Next we derive the unitary transformations in Hilbert space corresponding to the Euler rotations. Note that these transformations are described by complex 2×2 matrices. This arises because we restricted ourselves to a two level system (for instance quarks require 3×3 matrices). Problem 3.10 deals with an important result and offers a good opportunity to refresh your skills of handling complex 2×2 matrices. Importantly, not one but two unitary transformations correspond to a rotation in real space. This has no consequence for the operators (they transform like classical integer angular momentum operators) but the states become double valued.

§ 3.8.4: We now are in a position to derive a relation between the $s = 1/2$ angular momentum operators and rotations in the laboratory. With Eq. (3.210) we arrive at the fundamental conclusion that the spin operator S_z is equivalent to an operator for an infinitesimal rotation about the z axis (see Problem 3.20 for the formal proof). Problem 3.18 deals with the general case (i.e., rotation about an arbitrary axis) and is optional.

§ 3.8.5: In this section we show that the relations derived in the previous sections for $s = 1/2$ can be generalized to the case of arbitrary spin. This result provides the basis for the formal definition of angular momentum in § 3.9.1.

§ 3.9.3: Here we arrive at a *milestone in physics.* We find that for *half-integral* spin the physical system has to be rotated over 4π to regain the original wavefunction (rather than 2π as we expect from classical physics and as is the case for spherical harmonics). We say: half-integral angular momentum has “no classical analogue”. Read the subsection and make sure you are aware of this lack of classical analogy.

§ 3.11: In this section we apply the new knowledge. We demonstrate how we can generate the transformation matrices of § 3.10 with the systematic method of § 3.9.1.

§ 3.11.1 For a $s = 1/2$ system

§ 3.11.2 For a $s = 1$ system.

Minimum knowledge:

1. The *commutation relations*
$$[J_x, J_y] = i\hbar J_z,\ [J_y, J_z] = i\hbar J_x \text{ and } [J_z, J_x] = i\hbar J_y.$$
The *eigenvalue equations*
$$\begin{aligned}\mathbf{J}^2 \left|j, m\right\rangle &= j(j+1)\hbar^2 \left|j, m\right\rangle \\ J_z \left|j, m\right\rangle &= m\hbar \left|j, m\right\rangle ,\end{aligned}$$
The quantum numbers j and m are called *rotational quantum numbers*; for a given $\mathbf{J}$ these are either both *integral* or *half-integral.* The quantum number m is called the *magnetic quantum number* and is restricted to the interval $-j \leq m \leq j$. The action of the *shift operators* is given by
$$J_\pm \left|j, m\right\rangle = \sqrt{j\,(j+1) - m(m \pm 1)}\,\hbar \left|j, m \pm 1\right\rangle ,$$
where the choice for the positive sign is known as the *Condon and Shortley phase convention.*
2. Make sure that you can generate the *matrix representation* from the eigenvalue equations.
3. Be aware of the definition of the *polarization vector*: $\mathbf{P} = (\langle J_x/j\hbar\rangle, \langle J_y/j\hbar\rangle, \langle J_z/j\hbar\rangle)$.
4. The relations $R(\alpha, \beta, \gamma) = R_{z''}(\gamma)R_{y'}(\beta)R_z(\alpha)$ en $R(\alpha, \beta, \gamma) = R_z(\alpha)R_y(\beta)R_z(\gamma)$ and the definition of the Euler angles (see Fig. 3.7-b).
5. The expression for an arbitrary $s = 1/2$ state: $\left|\chi\right\rangle = \cos\theta/2 \left|\uparrow\right\rangle + e^{i\phi}\sin\theta/2 \left|\downarrow\right\rangle$ and its mapping onto the *Bloch sphere.*
6. The *inner product rules*:
$$\begin{aligned}\mathbf{L}\cdot\mathbf{S} &= L_xS_x + L_yS_y + L_zS_z \\ \mathbf{L}\cdot\mathbf{S} &= L_zS_z + \tfrac{1}{2}\left(L_+S_- + L_-S_+\right) \\ \mathbf{L}\cdot\mathbf{S} &= \tfrac{1}{2}(\mathbf{J}^2 - \mathbf{L}^2 - \mathbf{S}^2).\end{aligned}$$
7. Know how to apply the vector addition $\mathbf{J} = \boldsymbol{j}_1 + \boldsymbol{j}_2$ in a vector diagram and understand the triangle inequality
$$|j_1 - j_2| \leq J \leq j_1 + j_2.$$
8. The *Clebsch-Gordan decompositions "in both directions"* by using the closure relations
$$\begin{aligned}\left|JM\right\rangle &= \sum_{m_1=-j_1}^{j_1}\sum_{m_2=-j_2}^{j_2} \left|j_1m_1; j_2m_2\right\rangle\langle j_1m_1; j_2m_2\left|JM\right\rangle \\ \left|j_1m_1; j_2m_2\right\rangle &= \sum_{J=|j_1-j_2|}^{j_1+j_2}\sum_{M=-J}^{J} \left|JM\right\rangle \left\langle JM\right|j_1m_1; j_2m_2\rangle .\end{aligned}$$
9. Know that the Clebsch-Gordan coefficients can be rewritten in the form of *Wigner* 3*j symbols*. Make sure that you understand the graphical model. All *symmetry rules* as given in Appendix J.1 you should know by heart.

3 Angular momentum, optional material

§ 3.4.3: Here we give a few commutation relations for $\boldsymbol{j}_1$ and $\boldsymbol{j}_2$ with $\mathbf{J}$. These can be derived when needed. Check that you can do so, such that there is no need for memorizing them.

§ 3.4.4: Three important selection rules for calculating j_{1z}, j_{2z}, $j_{1\pm}$, $j_{2\pm}$, in the basis of $\mathbf{J}$ are given. Convince yourself that these rules are intuitively correct. The derivation can be found in Problems 3.7-3.9.

§ 3.4.5: If we want to calculate the matrix elements of j_{1z}, j_{2z}, $j_{1\pm}$, $j_{2\pm}$ in the basis of $\mathbf{J}$, it turns out that we need a new phase convention. No need to understand the exact details, but please familiarize yourself with the new convention, Eq. (3.99): *For $J' \neq J$ the matrix elements of j_{1z} are chosen to be real and non-negative*, $\langle J', M|j_{1z}|J, M\rangle \geq 0$. This implies - see Eqs. (3.103) en (3.105). Read the summary at the end of the section: $\langle J-1, M+1|j_{1+}|J, M\rangle \geq 0$ en $\langle J+1, M+1|j_{1+}|J, M\rangle \leq 0$.

§ 3.5: In this section we investigate the symmetry rules of the Clebsch-Gordan coefficients (CGCs). These are hard to recall. For this reason Wigner transformed the CGCs into $3j$-symbols. These have simple symmetry relations and the triangle inequality helps us to instantly see whether they vanish or not - see Fig. 3.4. In the latter case we have to look up the value in Appendix J or calculate them in Mathematica. For the hardliners the properties of the $3j$ symbols are derived. Us softies take comfort in the thought that this was ones properly done for us. In any case it is not part of the exam. Whatever, *you must be able to apply these rule*s. The symmetry relation can also be found in Appendix J.1. If you are wise you memorize them right now.

§ 3.5.1: In this section we discuss the coupling order and derive the symmetry relations of the CGCs.

§ 3.5.1.1: The exchange symmetry is special for two identical angular momenta. We demonstrate that the pair states are symmetric for integral and antisymmetric for half-integral angular momenta. This is of course important for the relation between spin and quantum statistics.

§ 3.5.2: We discussed the addition of angular momenta but does it make sense to subtract them? For classical arrow vectors this is evident. We simply have to reverse the arrow as sketched in Fig. 3.3. Interestingly, this principle works for integer angular momenta but in the half-integer case it does not! By inspection of the CGCs for the two situations it turns out that we have to include a phase jump of $(-1)^{2j_2}$, where $\boldsymbol{j}_2$ is thee angular momentum to be inverted - see Fig. 3.3. Not that this has only consequences for half-integral j_2.

§ 3.5.3: In this section we introduce the transformation from CGC to $3j$ symbol. The limited symmetry of the CGCs can be traced back to the presence of the bra side of the coefficients. By hermitic conjugation of the bra part we obtain a tensor product of 3 kets the must represent a scalar because we consider three vectors adding up to zero, $\boldsymbol{j}_1 + \boldsymbol{j}_2 + \mathbf{J} = 0$. The mentioned scalar is the $3j$ symbol.

§ 3.5.3.1: Important: in this section you find a summary of the symmetry relations - see also Appendix J.1. *Memorize them!* We do not promote this option in general but in this case the example of famous colleagues may convince you.

§ 3.5.3.2: Here you find the derivation of the phase rules for $3j$ symbols.

§ 3.5.3.3: Have a look at the examples of Fig. 3.4.

§ 3.7: We raise to the next level by coupling *three* angular momenta. The total angular momentum becomes $\mathbf{J} = \boldsymbol{j}_1 + \boldsymbol{j}_2 + \boldsymbol{j}_3$. The order of coupling emerges prominently because this can be done in several ways. We introduce recoupling coefficients to compare twee different coupling orders using their inner product, e.g. $\langle (j_{12}j_3)JM|(j_1j_{23})J'M'\rangle$. By careful use of the coupling rules we can express these recoupling coefficients in the form of a sum of products of *four* $3j$ symbols - see Eq. (3.166) en Appendix J.2.

§ 3.7.1: When coupling 3 angular momenta (j_1, j_2, j_3) we actually have to account for 6 angular momenta $(j_1, j_2, j_3, j_{12}, j_{13}, j_{23})$. When coupling two angular momenta (j_1, j_2) this was restricted to only three (j_1, j_2, j_{12}). The latter could be visualized by the *triangle* of the vector model. For 6 angular momenta this is possible with a *tetraeder* - see Fig. 3.6. Using the symmetry of the tetraeder Wigner designed the $6j$ symbol. This is again a scalar because we require $\boldsymbol{j}_1 + \boldsymbol{j}_2 + \boldsymbol{j}_2 + \mathbf{J} = 0$. The general expression for the $6j$ symbol is derived in Problem 3.19. You can skip the derivations but have a close look at the symmetry rules compiled in § 3.7.1.1 and Appendix J.2.

§ 3.9: In this section we make a fresh start because angular momentum can be defined in a more fundamental way as an infinitesimal rotation.

§ 3.9.1 We give the formal definition of *orbital* angular momentum operator as an infinitesimal rotation.

§ 3.9.2: We generalize the new definition for *arbitrary* types of angular momentum. From this we obtain the commutation relations and, consequently, regain everything we learned about angular momentum in § 3.4.

§ 3.9.3: Here we arrive at a *milestone in physics*. We find that for *half-integral* spin the physical system has to be rotated over 4π to regain the original wavefunction (rather than 2π as we expect from classical physics and as is the case for spherical harmonics). We say: half-integral angular momentum has “no classical analogue”.

§ 3.9.4: Here we discuss the unitary transformations in Hilbert space corresponding to Euler rotations for the general case (arbitrary angular momentum). We meet the Wigner rotation matrices.

§ 3.9.5: From the Clebsch-Gordan decomposition we can derive the transformation properties of spherical tensor operators. We demonstrate this for spherical tensor operators $\mathbf{T}^{(0)}$ (rank 0), $\mathbf{T}^{(1)}$ (rank 1) and $\mathbf{T}^{(2)}$ (rank 2).

§ 3.10: In this section we make the step from vector operators to tensor operators of general order. This is the final generalization. The section is important for the chapter on electric hyperfine structure, which is not part of the course. A nice detail is that the methods introduced allow for solving the Gaunt integral as shown in Problem 3.24.

4 Fine structure of hydrogen-like atoms - part 1

Arguably this is the point where the lectures really start: we are well prepared to describe the detailed structure of hydrogen-like atoms. We first focus on the atomic *fine structure* and in Chapter 4 we turn to the *hyperfine structure*. The term *fine structure* refers to deviations from the principal structure related to properties of the *electronic motion relative to the nucleus*. The *hyperfine structure* is related to the *nuclear structure*. First we calculate relativistic corrections to the electronic energies. This involves two contributions, a kinetic energy correction (the *relativistic mass correction*) and a potential energy correction (the *Darwin correction*). Then, we turn to the Lorentz force experienced by the electron when we apply a magnetic field (this breaks the rotation symmetry). This is the origin of the *orbital magnetism* (orbital *Zeeman interaction* and *Larmor precession* of the angular momentum) as well as of *diamagnetism*. Next we postulate the *electron spin* (which is also a relativistic phenomenon) and obtain the spin-Zeeman interaction. As it turns out it is in general impossible to completely switch of the magnetic field because a moving electron always experiences a *velocity induced magnetic field* in the electric field of the nucleus. The electron spin couples to this internal field, a phenomenon known as *spin-orbit interaction*. Further, also the *Lamb shift* is a fine structure effect, related the coupling of the atomic dipole to the zero-point fluctuations of the electromagnetic field. As quantum electrodynamics (QED) is not part of this course on atomic structure it is also not part of the exam. Compiling all contributions we obtain a Hamiltonian that can be reduced to an *effective spin Hamiltonian* for the atomic fine structure. This is the work horse of elementary atomic physics. With this Hamiltonian all interactions (except the Lamb shift) can be calculated to very good approximation usually by ordinary perturbation theory.

To study at home

Chapter 4 - part 1: The notions *relativistic mass correction, Darwin correction, Zitterbewegung and Compton wavelength* λ_C, *Lorentz force* $\mathbf{F}$, *generalized potential function* $V(\mathbf{r},\mathbf{v},t)$, *vector potential* $\mathbf{A}(\mathbf{r})$, *scalar potential* $\varphi(\mathbf{r})$, *kinetic momentum* $m\mathbf{v}$, *electromagnetic momentum* $q\mathbf{A}$, *canonical momentum* $\mathbf{p}$, *Hamiltonian* H, *lagrangian* L, *kinetic energy* T, *diamagnetic moment* $\boldsymbol{\mu}_{dia}$ and *magnetic polarizability* α_M, *orbital magnetic moment* $\boldsymbol{\mu}_L$, *spin magnetic moment* $\boldsymbol{\mu}_S$, *Bohr magneton* μ_B, *Larmor precession*, *Stern-Gerlach method.*

Read the introduction. Realize yourself how important hydrogen has been for the development of modern physics.

§ 4.1: Relativistic and radiative shifts:

- § 4.1.1: The derivation of the *relativistic mass correction* H_r^{mass} starting from of the relativistic Hamiltonian. This is the correction term for the kinetic energy of the electron (see Fig. 4.1).
- § 4.1.2: The *Darwin correction* H_r^{Darwin} is the correction term for the potential energy of the electron. The origin of this correction can be visualize heuristically as a kind of "smearing" of the electronic charge distribution over the *Compton wavelength* $\lambda_C = \alpha a_0$ as a consequence of the *Zitterbewegung* of relativistic electrons (see Fig. 4.1). This reduces the electrostatic attraction of electrons close to the nucleus (s electrons). A similar reduction results from the finite size of the atomic nucleus. - see Problem 4.1.
- § 4.1.3: The *Lamb shift* is a really important phenomenon but, unfortunately, does not fit within the scope of this lecture (see Fig. 4.1). The origin of this shift can also be visualized as a kind of "smearing of the charge distribution, in this case over a distance much smaller than λ_C but much larger than r_p (*proton charge radius*) as a result of the *zero point fluctuations* of the electromagnetic field. This heuristic model is known as *Welton's* picture of the Lamb shift.

§ 4.2: Refresh your knowledge of classical mechanics (Appendix C): the relation $H = \mathbf{p}\cdot\mathbf{v} - L$ between the Hamiltonian and the lagrangian $L = T - V$ and the derivation of the Hamiltonian for an electron in a classical electromagnetic field

$$\mathcal{H} = \frac{1}{2m}(-i\hbar\boldsymbol{\nabla} - q\mathbf{A})^2 + q\varphi(r)\,.$$

Study carefully the derivation of the effective Hamiltonian for an atom in a magnetic field $\mathbf{B}(\mathbf{r})$

$$\mathcal{H} = \mathcal{H}_0 - \frac{q}{2m}\mathbf{L}\cdot\mathbf{B}(\mathbf{r}) + \frac{q^2}{8m}r_\perp^2\mathbf{B}^2(\mathbf{r}),$$

obtained using the Coulomb gauge, $\boldsymbol{\nabla}\cdot\mathbf{A} = 0$, and the expression for the vector potential of a homogeneous magnetic field, $\mathbf{A} = \frac{1}{2}\mathbf{B}\times\mathbf{r}$. Problem 4.2 is optional but very useful to refresh your classical mechanics.

§ 4.3: Hydrogen-like atoms in an external magnetic field:

§ 4.3.1: Have a close look at how a *magnetic moment* can be demonstrated with the *Stern-Gerlach method* (see Fig. 4.3. Understand the difference between a *permanent* and an *induced* magnetic moment as well as the concept of *magnetic polarizability.* Take careful notice of the sign conventions for the magnetic moment $\boldsymbol{\mu}_L = \gamma_L\mathbf{L} = -g_L\mu_B\,(\mathbf{L}/\hbar)$ realize that the gyromagnetic ratio γ_L is *negative* but the g_L factor is (by definition) *positive.*

§ 4.3.2: Study the notions *diamagnetism*, *diamagnetic susceptibility* and *magnetization.*

§ 4.3.3: Understand the difference between the notion of *orbital-magnetic moment vector operator* $\boldsymbol{\mu}_L$, *"the" orbital-magnetic moment* μ_L, *effective orbital-magnetic moment* μ_{eff} and *magnitude of the orbital magnetic moment* $\sqrt{\langle\boldsymbol{\mu}_L\cdot\boldsymbol{\mu}_L\rangle}$. The Zeeman Hamiltonian for the orbital motion is $\mathcal{H}_Z = -\boldsymbol{\mu}_L\cdot\mathbf{B}$. Study Fig. 4.4-a/b.

§ 4.3.4: The torque on the angular momentum, $d\mathbf{L}(t)/dt = \boldsymbol{\mu}_L\times\mathbf{B}$ gives rise to *Larmor precession* of $\boldsymbol{\mu}_L$ about the field direction, $\omega_L = g_L(e/2m_e)B$. Calculate the level splitting by first-order perturbation theory (orbital Zeeman effect). Study Fig. 4.4-c.

§ 4.4.5: In this section we *postulate spin* - understand why and, in particular, why spin differs fundamentally from a classically rotating sphere of charge.

§ 4.3.6: Familiarize yourself with the concepts of *electron-spin, g-factor, gyromagnetic ratio, electron anomaly*, *intrinsic magnetic moment* and *spin-Zeeman effect.* Beware of sign conventions in expressions for the magnetic moment $\boldsymbol{\mu}_s = \gamma_e\mathbf{S} = -g_e\mu_B\,(\mathbf{S}/\hbar)$; realize that (just as for $\boldsymbol{\mu}_L$) the gyromagnetic ratio γ_e is *negative* but the g_e factor is (by definition) *positive.* The Hamiltonian takes the form $\mathcal{H}_Z = -\boldsymbol{\mu}_s\cdot\mathbf{B}$ and the torque is given by $d\mathbf{S}(t)/dt = \boldsymbol{\mu}_L\times\mathbf{B}$.

§ 4.3.7: Here you find the full Zeeman Hamiltonian for the electron.

Minimum knowledge:

1. The origin of the relativistic and radiative shifts: Relativistic mass correction, Darwin term and Lamb shift and their dependence on the angular momentum.

2. The *Zeeman Hamiltonian* for the electron

$$\mathcal{H}_Z = -\boldsymbol{\mu}_S\cdot\mathbf{B} - \boldsymbol{\mu}_L\cdot\mathbf{B} - \tfrac{1}{2}\boldsymbol{\mu}_{dia}\cdot\mathbf{B}.$$

3. The definitions of the *magnetic moments*, of the *Bohr magneton* μ_B and the *magnetic polarizability* α_M:

$$\left.\begin{aligned} \boldsymbol{\mu}_L &= \gamma_L \mathbf{L} = -g_L \mu_B \,(\mathbf{L}/\hbar)\; g_L \simeq 1 \\ \boldsymbol{\mu}_S &= \gamma_e \mathbf{S} = -g_e \mu_B \,(\mathbf{S}/\hbar)\;\; g_e \simeq 2 \end{aligned}\right\} \mu_B = (e\hbar/2m_e)$$

$$\boldsymbol{\mu}_{dia} = -\alpha_M \mathbf{B} \qquad\qquad \alpha_M \simeq (e^2/4m_e)\langle r_\perp^2 \rangle.$$

4. The energy splittings of the *fine* structure are typically a factor α^2 smaller than the energy splitting of the *principal* structure.

4 Fine structure of hydrogen-like atoms - part 2

The "Zeeman" magnetic field can never be switched off completely because a *moving* electron in an electric field always experiences a (motion induced) magnetic field. In the atom the direction of this field is directed along $\mathbf{L}$. The electron spin $\mathbf{S}$ couples to this *internal field*, a phenomenon known as *spin-orbit coupling* (Russell-Saunders coupling in the case of many-electron atoms). Therefore, in the absence of an external field the spin $\mathbf{S}$ and the orbital angular momentum $\mathbf{L}$ couple to a total angular momentum $\mathbf{J} = \mathbf{L} + \mathbf{S}$. This spin-orbit coupling is accounted for by a new term in the Hamiltonian, $\mathcal{H}_{LS} = \xi(r)\mathbf{L} \cdot \mathbf{S}$. This term (partly) lifts the n^2 degeneracy of the Schrödinger Hamiltonian $\mathcal{H}_0$. Since $\mathbf{L} \cdot \mathbf{S}$ commutes with $\mathcal{H}_0$ we can calculate this lifting with "ordinary" perturbation theory. However, as the prefactor $\xi(r)$ does *not* commute with $\mathcal{H}_0$ this calculation is only accurate to first order in perturbation theory. Usually this is sufficient because the second-order correction is negligible. Unfortunately, the coupling term $\mathcal{H}_{LS}$ does not commute with the Zeeman Hamiltonian $\mathcal{H}_Z$. Therefore, the level splitting in a magnetic field has to be calculated with perturbation theory for a degenerate level. In many cases this is possible by solving a 2×2 secular equation. Fortunately, we can analyze the fine structure with first-order perturbation theory both in the low field limit, $\langle \mathcal{H}_Z \rangle \ll \langle \mathcal{H}_{LS} \rangle$, and in the high field limit, $\langle \mathcal{H}_{LS} \rangle \ll \langle \mathcal{H}_Z \rangle$. As $m_j = m_l + m_s$ is a good quantum number in any field the low- and high-field information is sufficient to sketch the full fine-structure diagram.

To study at home

Chapter 4 - part 2 (starting§ 4.4): *Coupling of angular momentum and the Term notation (spectroscopic notation)*, *Clebsch-Gordan decomposition*, *Landé interval rule*, *center-of-mass rule*, *low-field limit - Landé factor*, *high-field limit - Paschen-Back effect*, *Wigner-Eckart theorem. Screening*, *effective charge*, *quantum defect*, *Rydberg limit*, *low-field limit - Landé factor*, *high-field limier - Paschen-Back effect.*

§ 4.4: Fine-structure Hamiltonian:

- § 4.4.1: The introduction of the total angular momentum $\mathbf{J} = \mathbf{L} + \mathbf{S}$ with the corresponding *coupled* basis $\{|lsJm_J\rangle\}$ (the *Russell-Saunders basis*) usually written shortly as $\{|Jm_J\rangle\}$ and the decomposition of this basis in terms of the *uncoupled* basis $|lm_lsm_s\rangle \equiv |lm_l\rangle \otimes |sm_s\rangle$ (the *Paschen-Back basis*) by means of a *Clebsch-Gordan decomposition.* In this section we apply the method of § 3.2. Have a close look how the commutation relations are proven: Problem 4.4-4.7. Problem 4.8 is *very important!*
- § 4.4.2: Study how the *motion-induced* field $\mathbf{B}_L$ arises.
- § 4.4.3: Study how $\mathbf{B}_L$ this reduces to the *spin-orbit field* $\mathbf{B}_{LS}$ by correcting for the *Thomas precession.* Coupling the spin to the field $\mathbf{B}_{LS}$ yields the spin-orbit interaction.
- § 4.4.4: Make sure that understand how the spin-orbit Hamiltonian $\mathcal{H}_{LS} = \xi(r)\mathbf{L} \cdot \mathbf{S}$ arises, in particular how the coupling strength $\xi(r)$ is defined.
- § 4.4.5: By collecting all terms discussed thus far we obtain the *fine-structure Hamiltonian.*

§ 4.5: Fine structure in zero field:

- § 4.5.1: Study how we obtain the *effective* fine-structure Hamiltonian, in particular how the coupling constant ζ_{nl} is defined.
- § 4.5.2: Study Fig. 4.8 by making sure that you can derive the shift rules. Take notice of the *Landé interval rule,* $\Delta W_J = \Delta E^{LS}_{n,J} - \Delta E^{LS}_{n,J-1} = \zeta_{nl} J$, and the *center-of-mass rule* for the energy levels. Problem 4.9 is optional. Calculate the fine-structure splitting and verify the center-of-mass rule for hydrogen-like atoms.

§ 4.5.3: Note that the fine-structure levels of *hydrogen* depend only on j and not on l and/or s independently.

§ 4.6: We now turn to the *alkali-like* atoms.

§ 4.6.1: Here we discus one of the great puzzles from the development of Atomic Physics (see Fig, 4.9): Why do we need only two quantum numbers (n, j) to describe the ground state of hydrogen but need three (n, l, s) for the alkali-like atoms?

§ 4.6.2: Study the large $n\,{}^2S$ - $n\,{}^2P$ splitting in the alkalies. Understand the role of the core electrons in screening the nuclear charge. For p electrons this is core is more efficient than for s electrons. The absence of core electrons in hydrogen give rise to an (almost complete) degeneracy of the $n\,{}^2S$ and $n\,{}^2P$ terms (see Fig, 4.9). Fig, 4.10 shows how this depends on the alkali (i.e., the size of the core). Note that for the heavy alkali the spin-orbit becomes large (i.e., visible even in Fig, 4.10). This is caused by the large nuclear charge (in spite of the screening by the core electrons).

§ 4.6.2.1: The deviation from the hydrogenic value of the principal quantum numbers (integers in the case of hydrogen) arises from screening of the nuclear charge. The screening can be quantified using three closely related notions: the *screening constant*, the *effective nuclear charge* and the *quantum defect*. Digest how these are related. Study Fig. 4.10-b and Fig. 4.11 in this context, as well as Table 4.1. Understand what is meant by the *Rydberg limit* of the quantum defect.

§ 4.6.2.2: In this section you can read how the atom contracts for increasing nuclear charge. This section is important because it will help you later to understand some remarkable anomalies in the periodic system. Can you define what is meant by an iso-electronic series? Very important: Understand why the s orbitals are preferentially bound. In Fig. 4.12 you find the radial distribution functions $2s$ and $2p$ orbitals.

§ 4.6.3: (*optional*) Screening also affects the fine structure.

§ 4.6.4: (*optional*) Understand how the calculation of the transition dipoles changes in the presence of fine structure.

§ 4.7: Next we study the influence of a magnetic field.

§ 4.7.1: Read the introduction. When dealing with a degenerate level and two non commuting perturbation operators ($\mathcal{H}_Z$ and $\mathcal{H}_{LS}$) we have to solve the secular equation. This is equivalent to the diagonalization of the perturbation matrix.

§ 4.7.2: We express the elements of the perturbation matrix in the uncoupled basis (Zeeman basis), $\mathcal{H}'_{m_j m'_s m_s} = \langle nlm'_l sm'_s|\mathcal{H}'\,|nlm_l sm_s\rangle$. Note that these matrix elements vanish if m_s and m'_s differ more than one unit of angular momentum.

§ 4.7.3: Importantly, the matrix consists of (1×1) and (2×2) blocks along the diagonal. Hence, we do not have to diagonalize more than a (2×2) matrix. Understand the difference between pure spin states (linear Zeeman shift) and mixed spin states (non-linear Zeeman shift). Study the crossover behavior from low field to high field in Fig. 4.15. Note the definition of the crossover field B_{fs} as the point where the low-field and high-field tangents intersect. In Problem 4.12 we derive a relation for the crossover field, handy to estimate when you leave the low-field limit.

§ 4.7.4: Analyze the *high-field limit* using the uncoupled basis (Paschen-Back basis) treating the spin-orbit Hamiltonian $\mathcal{H}_{LS}$ as a perturbation. This can be done using first-order perturbation theory. This section is very important.

§ 4.7.5: Analyze the *low-field limit* using the coupled basis (Russell-Saunders basis) and treating the Zeeman Hamiltonian $\mathcal{H}_Z$ as a perturbation. Also this limit can be described with first-order perturbation theory. Also this section is very important. Familiarize yourself with the Wigner-Eckart theorem in the form (4.200). You have to know this expression but its algebraic derivation is not part of the exam (Problem 4.14 and Appendix K are not part of the exam). However, you should be able to reproduce the heuristic derivation using the vector diagram (Fig. 4.6) and Eq. (4.200). Have a close look at the derivation of the Landé factor g_J.

§ 10.7.5: Study this section as an example of the low-field limit. Problem 4.14 offers a derivation of the Wigner-Eckart theorem for the special case of L_z. This proof gives you an impression how the full proof is constructed. Problem 4.14 is optional.

Minimum knowledge:

1. Realize two important properties of commutation relations:
    - if A commutes with C and B commutes with C *this does not imply that* A and B also commute with each other. Example: $[L_z, \mathbf{L}^2] = 0$ and $[\mathbf{L} \cdot \mathbf{S}, \mathbf{L}^2] = 0$ but $[L_z, \mathbf{L} \cdot \mathbf{S}] \neq 0$.
    - if A does *not* commute with C and B does *not* commute with C, it still can be such that $A + B$ *does commute* with C. Example: $[L_z, \mathbf{L} \cdot \mathbf{S}] \neq 0$ and $[S_z, \mathbf{L} \cdot \mathbf{S}] \neq 0$ but $[J_z, \mathbf{L} \cdot \mathbf{S}] = [L_z + S_z, \mathbf{L} \cdot \mathbf{S}] = 0$.
2. The *vector coupling diagram* (Fig. 3.9 and Fig. 4.6) with the *triangle inequality* and the *spectroscopic Term notation.*
3. The *Clebsch-Gordan decompositions*

$$|jm_j\rangle = \sum_{m_l=-l}^{l} \sum_{m_s=-s}^{s} |lm_l sm_s\rangle\langle lm_l sm_s\,|jm_j\rangle$$
$$|lm_l sm_s\rangle = \sum_{j=|l-s|}^{l+s} \sum_{m_j=-j}^{j} |jm_j\rangle\,\langle jm_j\,|lm_l sm_s\rangle\,.$$

4. The *Landé interval rule (including derivation):* $\Delta W = \Delta E^{LS}_{n,J} - \Delta E^{LS}_{n,J-1} = \zeta_{nl} J$.
5. The *center of gravity rule:*

$$\frac{1}{(2l+1)\,(2s+1)} \sum_{J=|l-s|}^{l+s} (2J+1)\,\Delta E^{LS}_{n,J} = 0.$$

6. Screening by core electrons: the rotational structure is not affected (central symmetry is conserved).
7. Be familiar with the concepts *quantum defects* and *screening efficiency* and *isoelectronic pairs.*
8. Understand the preferential binding of s electrons.
9. Understand the effect of screening on the fine structure and in particular on the spin-orbit coupling. Know that the energy difference between the D1 and D2 transitions in alkalies grows significantly with Z, but not as rapid as expected due to screening.
10. The perturbation theory for high field.

11. The perturbation theory for low field including the Wigner-Eckart theorem

$$\langle nlsJm_J|\, L_z\, |nlsJm_J\rangle = \langle lsJ\, \|L\|\, lsJ\rangle\, \langle Jm_J|\, J_z\, |Jm_J\rangle$$
$$\langle nlsJm_J|\, S_z\, |nlsJm_J\rangle = \langle lsJ\, \|S\|\, lsJ\rangle\, \langle Jm_J|\, J_z\, |Jm_J\rangle\,,$$

with

$$\langle nlsJm_j|\, L_z\, |nlsJm_j\rangle = \frac{\langle lsJm_j|\, (\mathbf{L}\cdot\mathbf{J})\, J_z\, |lsJm_j\rangle}{\langle lsJm_j|\, \mathbf{J}^2\, |lsJm_j\rangle} = \langle lsJ\, \|L\|\, lsJ\rangle\, \langle lsJm_j|\, J_z\, |lsJm_j\rangle\,,$$

where

$$\langle lsJ\, \|L\|\, lsJ\rangle = \frac{\langle lsJm_j|\, \mathbf{L}\cdot\mathbf{J}\, |lsJm_j\rangle}{\langle lsJm_j|\, \mathbf{J}^2\, |lsJm_j\rangle} = \frac{J(J+1)+l(l+1)-s(s+1)}{2J(J+1)}.$$

and the analogue expression for S_z.

12. The expression and derivation of the Landé factor

$$g_J = g_L\langle lsj\, \|L\|\, lsj\rangle + g_e\langle lsj\, \|S\|\, lsj\rangle \simeq 1 + \frac{j(j+1)+s(s+1)-l(l+1)}{2j(j+1)}.$$

5 Hyperfine structure of hydrogen-like atoms - part 1

The nucleus has a spin $\mathbf{I}$ and associated with this a magnetic moment $\boldsymbol{\mu}_I = \gamma_I \mathbf{I}$, where γ_I is the gyromagnetic ratio, which (depending on the nucleus) can be positive, negative or zero. This gives rise to a nuclear-Zeeman effect described by the effective Hamiltonian

$$\mathcal{H}_Z = \gamma_I \, \mathbf{I} \cdot \mathbf{B}.$$

In view of the presence of the nuclear magnetic moment the electron always experiences the associated magnetic field. This gives rise to a coupling, the *hyperfine interaction*, between the nuclear spin $\mathbf{I}$ and the total angular momentum $\mathbf{J} = \mathbf{L} + \mathbf{S}$ of the electron. This coupling can always be written (to very good approximation) in the form

$$\mathcal{H}_{IJ} = a_{\mathrm{hfs}} \, (\mathbf{I} \cdot \mathbf{J})/\hbar^2,$$

but the coupling constant a_{hfs} has a different origin for $l = 0$ as compared to $l \neq 0$. The hyperfine coupling give rise to splitting of the fine structure levels which can be calculated by first-order perturbation theory. Just as for the fine structure we find an interval rule and a center-of-gravity rule. Applying the theory to the hyperfine splitting of the hydrogen ground state ${}^2S_{1/2}$ we already find at this elementary level an accuracy of $1 : 10^4$.

To study at home

Read the introduction. Hyperfine structure finds its origin in the properties of the nucleus. Take notice of the various contributions. It turns out that even with a superficial understanding of the nucleus the hyperfine structure can be described with great precision. In Chapter 5 we focus on the *magnetic* hyperfine structure.

§ 5.1.1: Just as in the case of electron spin we associate a magnetic moment to the nuclear spin. Note the sign conventions, $\boldsymbol{\mu}_I = \gamma_I \mathbf{I} = g_I \mu_N \, (\mathbf{I}/\hbar)$; realize the in the case of nuclear spin both positive and negative values can be observed for the g_I factor and the gyromagnetic ration $\gamma_I = g_I \mu_N/\hbar$. The Hamiltonian is again of the generic type, $\mathcal{H}_Z = -\boldsymbol{\mu}_I \cdot \mathbf{B}$, and the torque is described by $d\mathbf{I}(t)/dt = \boldsymbol{\mu}_I \times \mathbf{B}$.

  § 5.1.2: The introduction of the total angular momentum $\mathbf{F} = \mathbf{J} + \mathbf{I}$ with the corresponding *coupled* basis $\{|IJFm_J\rangle\}$ often written shortly as $\{|Fm_F\rangle\}$. The coupling is illustrated in Fig. 5.1. Verify yourself how this basis can be decomposed in the *uncoupled* basis $|Im_IJm_J\rangle \equiv |Im_I\rangle \otimes |Jm_J\rangle$ (the *Paschen-Back basis*) with the aid of a *Clebsch-Gordan decomposition.*

§ 5.2: Magnetic hyperfine interaction:

  § 5.2.1: Study how we formulate the Hamiltonian for the *magnetic* hyperfine interaction. Refresh your knowledge of the magnetic dipole-dipole interaction by making Problem 5.1.

  § 5.2.2: Understand the three contributions to the magnetic hyperfine interaction $\mathcal{H}_{\mathrm{hfs}}$: (a) the *Fermi-contact interaction* $\mathcal{H}_{\mathrm{Fermi}}$, where the magnetic moment $\boldsymbol{\mu}_e$ of the electron (hence, also the spin $\mathbf{S}$) couples to the magnetic field *inside* the nucleus - this only happens for $l = 0$ (in this case $\mathbf{J} = \mathbf{S}$); (b) the *nuclear spin-orbit coupling* $\mathcal{H}_{LI}$, by which the magnetic moment $\boldsymbol{\mu}_I$ of the nucleus (hence, also the spin $\mathbf{I}$) couples to the magnetic field associated to the orbital angular momentum $\mathbf{L}$ of the electron. This field is only nonzero for $l \neq 0$; i.e., in the presence of orbital angular momentum; (c) the *magnetic dipole-dipole interaction* $\mathcal{H}_{dd}$ between the magnetic moment $\boldsymbol{\mu}_e$ of the electron (hence, also the spin $\mathbf{S}$) and the magnetic moment $\boldsymbol{\mu}_I$ of the nucleus (hence, also the spin $\mathbf{I}$); averaged over the orbital motion this interaction is nonzero only for $l \neq 0$.

§ 5.2.3: In this section you find the tensor expression for the magnetic dipole-dipole interaction. In Problem 5.2 we demonstrate the decomposition in tensor components. *This section is not part of the exam.*

§ 5.3: Hyperfine interaction in zero field.

§ 5.3.1: We start with an outline to prepare us for the derivation. It turns out that, in spite of three contributions ($\mathcal{H}_{\text{hfs}} = \mathcal{H}_{LI} + \mathcal{H}_{dd} + \mathcal{H}_{\text{Fermi}}$), the magnetic hyperfine interaction assumes an extremely simple form: $\mathcal{H}_{\text{hfs}} = a_{\text{hfs}}\,(\mathbf{I}\cdot\mathbf{J})/\hbar^2$, be it that the expression for the coefficient differs for $l = 0$ from that for $l \neq 0$; so take close notice of the difference of the expressions for the hyperfine coefficient a_{hfs} for the cases $l = 0$ and $l \neq 0$. Notice, that in *both* cases *the sign of* a_{hfs} is determined by the *gyromagnetic ratio* γ_I of the nucleus.

§ 5.3.2: Convince yourself that the Fermi-contact term is the only term that contributes for $l = 0$.

§ 5.3.3: Notice how the sum of the dipole-dipole interaction and the nuclear-spin-orbit interaction give rise to an effective field $\mathbf{B}_J$ generated by the electron at the position of the nucleus. The calculation of this field is rather technical with the Wigner-Eckart theorem again playing a prominent role. In Problem 5.3 we show how to calculate the reduced matrix element $\langle nlsj||B_J||nlsj\rangle$. This derivation is quite typical and certainly recommended but is *not part of the exam.*

§ 5.3.4: In this section we calculate the hyperfine splitting in zero field for a given fine structure Term $n\,^{2s+1}L_J$. This can be done with ordinary perturbation theory because $\mathbf{I}\cdot\mathbf{J}$ commutes with the fine structure Hamiltonian. Verify that the perturbation is indeed diagonal in the coupled basis $\{|IJFm_F\rangle\}$.

§ 5.3.5: By subtracting the hyperfine shift of two subsequent F levels we obtain the *hyperfine interval rule* $\Delta W_F = \Delta E_F^{IJ} - \Delta E_{F-1}^{IJ} = a_{\text{hfs}}F$. The *center-of-gravity rule* is given without proof because it follows analogous to Problem 4.9 because the trace of the interaction matrix is invariant under unitary transformation.

§ 5.3.6: Pause a moment to appreciate our finding that at this point we can calculate the hyperfine splitting in the electronic ground state $1^2S_{1/2}$ of hydrogen with an accuracy of $1 : 10^4$. This transition played a major role in the development of precision time- and frequency measurement and in radio astronomy.

§ 5.3.7: (*optional*) This section is valuable for students with interest in optical dipole transitions between hyperfine-structure levels.

Minimum knowledge:

1. The *vector-coupling diagram* (Fig. 5.1) with *triangle inequality.*
2. The *nuclear-Zeeman Hamiltonian:*
$$\mathcal{H}_Z = \gamma_I\,\mathbf{I}\cdot\mathbf{B}$$
3. Understand the origin of the three contributions to the hyperfine interaction and be able to name them: *nuclear spin-orbit interaction, magnetic dipole-dipole interaction, Fermi contact interaction.*
4. The effective Hamiltonian for the *hyperfine coupling:*
$$\mathcal{H}_{\text{hfs}} = a_{\text{hfs}}\,(\mathbf{I}\cdot\mathbf{J})/\hbar^2.$$
5. Know that the sign of the hyperfine coefficient a_{hfs} is the same as the sign of the gyromagnetic ratio γ_I.

6. The *hyperfine interval rule:* within a fine structure Term the following rule holds for adjacent hyperfine levels
$$\Delta W_F = \Delta E_F^{IJ} - \Delta E_{F-1}^{IJ} = a_{\text{hfs}} F.$$

7. The *center-of-gravity rule:*
$$\frac{1}{(2I+1)(2J+1)} \sum_{F=|I-J|}^{I+J} \Delta E_F^{IJ} = 0.$$

8. The energy splittings of the *hyperfine* structure are typically a factor m_e/m_p smaller than the energy splitting of the *fine* structure.

5 Hyperfine structure of hydrogen-like atoms - part 2

In the second part of this chapter we add the Zeeman interaction to the hyperfine Hamiltonian. In complete analogy with the $\mathbf{L}\cdot\mathbf{S}$ coupling of the fine structure, also the $\mathbf{I}\cdot\mathbf{J}$ coupling term does *not* commute with the Zeeman Hamiltonian $\mathcal{H}_Z$. Therefore, the level splitting in a magnetic field has to be calculated with perturbation theory for a degenerate level. In many cases this is possible by solving a 2×2 secular equation. As special cases we find that both the low field limit, $\langle\mathcal{H}_Z\rangle \ll \langle\mathcal{H}_{\mathrm{hfs}}\rangle$, and the high field limit, $\langle\mathcal{H}_{\mathrm{hfs}}\rangle \ll \langle\mathcal{H}_Z\rangle$, can be solved with first-order perturbation theory.

To study at home

Chapter 5 - part 2 (from .§ 5.4): We meet subsequently *perturbation theory in the uncoupled basis*, the notions *pure state* and *mixed state*, *high-field limit - Paschen-Back effect*, *low-field limit - g_F factor*, *Wigner-Eckart theorem, followed by a discussion* of the hyperfine structure of alkali atoms (as examples of hyperfine structure in one-electron atoms).

§ 5.4: Hyperfine structure in an applied magnetic field: Take notice of the effective spin Hamiltonian of the atom with fine structure as well as hyperfine structure. Understand what is meant by the *coupled* and the *uncoupled* basis of the hyperfine structure and why the *coupled basis is the low-field basis* and the *uncoupled basis the high-field basis.* Study the Zeeman effect in the presence of hyperfine interaction and note the close similarity with the Zeeman effect in the case of fine structure.

§ 5.4.1: In this section we derive expressions for the diagonal and the off-diagonal matrix elements of the hyperfine perturbation matrix in the uncoupled representation; i.e., the Zeeman basis $\{|nIm_Ijm_j\rangle\}$.

§ 5.4.2: Because the $\mathbf{I}\cdot\mathbf{J}$ coupling does *not* commute with the Zeeman Hamiltonian we have to use perturbation theory for a degenerate level. As explained in Appendix H it is our task to diagonalize the Hamiltonian. This amounts to solving the characteristic equation of the eigenvalue problem (the secular equation). We do this using the *uncoupled basis* (note that the same solutions can also be obtained in the coupled basis) because in this representation the perturbation matrix is block diagonal, with (1×1) and (2×2) blocks along the diagonal. Hence, we do not have to diagonalize more than a (2×2) matrix, see Appendix H.4. For atoms with $J=1/2$ (like hydrogen) not only the energies but also the corresponding states are determined. Understand the difference between pure spin states (linear Zeeman shift) and mixed spin states (non-linear Zeeman shift). Study in Fig. 5.5 the crossover behavior from low field to high field, in particular the difference between $\gamma_I>0$ and $\gamma_I<0$. Note the definition of the crossover field B_{hfs} as the point where the low-field and high-field tangents intersect.

§ 5.4.3: In this section we calculate the high-field limit. We apply the rule that off-diagonal terms contribute only in higher order to the energy shifts. Notice the intersection of the upper hyperfine levels at 16.7 Tesla in hydrogen. This happens when the nuclear Zeeman shift equals the zero-field splitting.

§ 5.4.4:hen we calculate the low-field limit using the Wigner-Eckart theorem, like in the zero-field case. We find that, to good approximation, for $j=1/2$ the g_F factor is given by

$$g_F \simeq \pm g_J\frac{1}{2I+1}\quad\text{for } F=I\pm1/2;\ j=1/2;\ F>0.$$

where g_J is the g factor of the *fine-structure* Term under consideration.

§ 5.4.5: Here we go to second order in perturbation theory. In low field this results in a quadratic correction known as the quadratic Zeeman effect.

§ 5.5: Ground state hyperfine structure of hydrogen-like atoms:
Examples:

§ 5.5.1: Solving the secular equation for $S = 1/2, I = 1/2, \gamma_I > 0$ (hydrogen)

§ 5.5.2: Solving the secular equation for $S = 1/2, I = 1, \gamma_I > 0$ (deuterium, lithium-6)

§ 5.5.3: Solving the secular equation for $S = 1/2, I = 3/2, \gamma_I > 0$ (various alkali atoms)

§ 5.5.4: Solving the secular equation for $S = 1/2, I = 4, \gamma_I < 0$ (potasium-40)

Minimum knowledge:

1. The atomic Hamiltonian with both fine structure and hyperfine structure,

$$\mathcal{H} = \mathcal{H}_0 + \mathcal{H}_r + \xi\, \mathbf{L} \cdot \mathbf{S} + \left(a_{\text{hfs}}/\hbar^2\right) \mathbf{I} \cdot \mathbf{J} + (g_J \mu_B J_z - g_I \mu_N I_z) B/\hbar$$

2. The perturbation theory for high field (analogous to fine structure) in high-field basis.

3. The perturbation theory for low field including the Wigner-Eckart theorem (analogous to fine structure)

$$\langle nlsJIFm_F|\, J_z\, |nlsJIFm_F\rangle = \langle JIF\, \|J\|\, JIF\rangle\, \langle Fm_F|\, F_z\, |Fm_F\rangle$$
$$\langle nlsJIFm_F|\, I_z |nlsJIFm_F\rangle = \langle JIF\, \|I\|\, JIF\rangle\, \langle Fm_F|\, F_z\, |Fm_F\rangle\, ,$$

$$\langle JIF||J||JIF\rangle = \frac{F(F+1) + J(J+1) - I(I+1)}{2F(F+1)}. \tag{P.3}$$

and the analogous expression for I. The expression for the g_F factor,

$$g_F = g_J \langle JIF||J||JIF\rangle - g_I (m_e/m_p) \langle JIF||I||JIF\rangle \underset{\text{for } J\neq 0}{\simeq} g_J \langle JIF||J||JIF\rangle$$

and the very good approximation for $J = 1/2$ atoms with $F \neq 0$

$$g_F \simeq \pm g_J \frac{1}{2I+1} \quad \text{for } J = 1/2,\ F \neq 0,$$

where $g_F < 0$ always corresponds to the state with the lowest multiplicity ($F = I - 1/2$) and $g_F > 0$ always with the state with of highest multiplicity ($F = I + 1/2$).

4. Make sure that you can sketch the hyperfine structure as a function of the magnetic field for atoms with $J = 1/2$ and given nuclear spin I and sign of γ_I.

6 Electric hyperfine structure (optional)

NB: This chapter *not part of the exam.*

7 Helium-like atoms

Right at the start of this chapter we find out that major changes occur when an atom contains more than a single electron. Actually, the complexity increases so strongly that the situation would be more or less hopeless of the *electrostatic interaction* would not be overwhelmingly *dominant*. In the theoretical description the electronic charge has to be distributed over the atom with great precision. This requires a new approach because analytical solutions (as used for hydrogen) do not exist. Aside from this, the electrostatic interaction is strongly affected by a phenomenon called *exchange*, completely absent in classical electrodynamics. With this knowledge in the back of our mind we can be positive to embark on larger atoms. We shall find that that the central symmetry is mostly preserved, so the classification with the quantum numbers n, l, m_l per electron remains useful. After refreshing the nomenclature we start with the helium atom. The electronic orbitals remain similar to those of hydrogen. The principal difference is found in the Coulomb repulsion between the electrons. The influence of this phenomenon we calculate with first-order perturbation theory.

After a discussion of helium in the ground state we turn to helium with two electrons in different orbital states. We find that in the latter case the two-electron state is degenerate under exchange of the electrons. This is called *exchange degeneracy.* The Coulomb repulsion between the electrons lifts this degeneracy. In this context we meet the two so-called *Coulomb integrals*: The *direct integral* $\mathcal{J}$ and the *exchange integral* $\mathcal{K}$. Using first-order perturbation theory for a two-fold degenerate level we find that the antisymmetric wavefunction has the lowest energy. Intuitively this is understandable because the Coulomb repulsion is smallest in this case. For two electrons in the same orbital (like in the helium ground state) only the *direct integral* contributes because in this case exchange degeneracy is absent. After this we learn how to evaluate the Coulomb integrals. At the end of the chapter we apply the newly acquired knowledge to calculate the ground state of helium.

To study at home:

Read the introduction.

§ 7.1: We formulate the Hamiltonian for an atom with exactly two electrons. First we solve the *unperturbed problem.* This is the Hamiltonian without Coulomb repulsion. We obtain the hydrogenic energy levels.

§ 7.1.1: The Coulomb repulsion between the electrons causes the charge distribution to inflate. Another way to look at the same phenomenon is to say that each of the electrons is somewhat shielded from the nuclear charge by the presence of the other electron. This is called screening. We calculate the energy of the atom using first-order perturbation theory. The *screening potential* added to *Coulomb potential* of the bare nucleus yields the *effective potential* for the electrons inside the atom.

§ 7.1.2: The ground-state energy can be reduced by optimization of the shape of the (normalized) wavefunction.

§ 7.1.3: Importantly, the screening is not complete. This makes it possible to bind an electron to a neutral hydrogen atom.. In this way we obtain the *negative* ion H^-. Binding of this ion cannot be obtained (explained) with perturbation theory. In contrast, this is possible by variation of the wavefunction. The actual variational calculus for H^- falls outside the exam but you should be able to explain why the H^- ion can exist.

§ 7.1.4: Our task is to determine the best effective potential. In this section we show that for the $1s^2$ product wavefunction of helium variational calculus leads us to the *Hartree equations.* This is a set of coupled Schrödinger equations (one for each electron) that can be solved with an iterative numerical procedure. As the wavefunctions determine the potential used in these Schrödinger equations, we have to iterate the procedure to obtain a *selfconsistent solution* (for wavefunctions and potential). The derivation of the Hartree equations is not part of the exam but you have to understand the principle of the self-consistent solution.

§ 7.2: In this section we meet a fundamental phenomenon. We learn that the ground state of helium (with two electrons in the *same* orbital) is nonmagnetic ($S = 0$) although magnetic states ($S = 1$) seems perfectly possible in view of the coupling rules for two spins $s = 1/2$ (see Section 3.2). Apparently, experiment forces us to exclude the symmetric spin state. This is known as the *Pauli exclusion principle.*

§ 7.3: For two electrons in *different* orbitals we note the occurrence of *exchange degeneracy* (when neglecting the Coulomb repulsion between the electrons). Lifting of this degeneracy by the Coulomb repulsion can be calculated with perturbation theory for a two-fold degenerate level. The perturbed states are given by the symmetric and anti-symmetric linear combinations of the unperturbed states. We introduce the *direct integral* $\mathcal{J}$ and the *exchange integral* $\mathcal{K}$. The direct integral corresponds to a *shift* of the degenerate levels. The exchange integral determines the *splitting.* The antisymmetric orbital has the lowest energy because the Coulomb repulsion is lowest in this case. We come to the conclusion that, experimentally, the antisymmetric orbital pair state is only observed in combination with a symmetric spin state and *vice versa.* Other combinations have to be excluded (Pauli exclusion principle).

§ 7.4: Study how the perturbation term from the Hamiltonian (the Coulomb repulsion between the electrons) can be rewritten as a sum over spherical harmonics. Verify how this enables closed expressions for $\mathcal{J}$ and $\mathcal{K}$ in terms of angular integrals and radial integrals.

§ 7.4.1: Convince yourself that it is straightforward to calculate the angular integrals with the aid of the integral over three spherical harmonics. Study Table 7.1.

§ 7.4.2: Convince yourself of the usefulness of introducing mean-field potentials (screening potentials) to calculate radial integrals. Problem 7.9 is of particular relevance.

§ 7.4.3: Calculate the ground-state energy of helium.

§ 7.4.4: Calculate the ground-state energy of metastable triplet helium.

§ 7.4.5: Read the discussion of helium-like atoms and make sure you understand why helium is spacial.

Minimum knowledge:

1. The name and definition of the notions: *orbital wavefunction* (short: orbital), *electron shells* en *subshells*, *equivalent electrons*, *Pauli principle*, *electron configuration, filled shell (closed shell), electron hole, valence electron* and *core electron.*

2. The Hamiltonian of the helium atom in Hartree atomic units,

$$\mathcal{H} = \sum_{i=1,2} \mathcal{H}_i + \mathcal{H}' = \sum_{i=1,2} \left(-\frac{1}{2}\boldsymbol{\nabla}_i^2 - \frac{Z}{\rho_i} \right) + \frac{1}{\rho_{12}}.$$

3. The name and definition of the *direct integral* $\mathcal{J}$ and the *exchange integral* $\mathcal{K}$

$$\mathcal{J} = (nlm_l; n'l'm_{l'}|\frac{1}{\rho_{12}}|nlm_l; n'l'm_{l'}) = \sum_{k=0}^{\infty} a^k(lm_l; l'm_{l'})F^k(nl; n'l')$$
$$\mathcal{K} = (nlm_l; n'l'm_{l'}|\frac{1}{\rho_{12}}|n'l'm_{l'}; nlm_l) = \sum_{k=0}^{\infty} b^k(lm_l; l'm_{l'})G^k(nl; n'l').$$

4. For equivalent electrons $G^k(nl;nl) = F^k(nl;nl) > 0$ and since $b^k(lm_l;l'm_{l'}) \geq 0$ for all values of k, the exchange integral is positive definite: $\mathcal{K}(nlm_l;nlm_l') > 0$.

8 Central field approximation for many-electron atoms

In this chapter we continue with the approach that turned out so successful for helium. Also for many-electron atoms the concept of *screening* is of central importance. We show how the Hamiltonian can be reduced to a Hamiltonian with central symmetry (§ 8.1) by neglecting the *correlations* between the electrons. In this way we obtain the *central field approximation.* In the remaining part of the section we analyze four approximations in which central fields are used to describe many-electron atoms. First we discuss the atomic model with *noninteracting electrons* (§ 8.2). The second example is the *Thomas-Fermi model for the atom* (§ 8.3). Next we discuss in § 8.4 the Hartree equations, already introduced in the discussion of the helium atom. The Hartree method can be regarded as the first step towards a modern *mean-field* theory. As a last example we discuss in § 8.5 the semi-empirical *quantum-defect approach* and show how this approach can serve to calculate electric-dipole transitions in alkali-like atoms. In hindsight the validity of the central field approximation provides the justification of the treatment of alkali atoms as hydrogen-like atoms as was done in previous chapters, in particular when discussing the atomic hyperfine structure in Chapter 5.

To study at home:

Read the introduction.

§ 8.1: Study how we introduce the screening potential and which terms are neglected in the *central field approximation.* Make sure that you understand that in this approximation *correlations* between electrons are neglected.

§ 8.2: Study the discussion about *non-interacting electron atoms.* Convince yourself that even under this rude approximation the atomic sequence in the *periodic system is correctly predicted for the light atoms.* Only the first paragraph is part of the exam.

§ 8.3: (*optional*) The *Thomas-Fermi central field*, the *atomic model of Thomas and Fermi* and *Thomas-Fermi screening.*

§ 8.4: Digest the principle of a *selfconsistent mean field solution.* Study what is meant by the Hartree equations.

§ 8.5: (*optional*) Alkali-like atoms are well-suited for a description with a central field approximation. A semi-empirical description emerges by using *quantum defects*, also known as *Rydberg corrections.*

> § 8.5.1: (*optional*) This section is about estimating radial integrals with the method of Bates en Damgaard.

Minimum knowledge:

1. All mentioned notions: *nuclear screening, central symmetry*, *central field approximation*, *non-interacting electrons, Hartree mean field*, *selfconsistent solution*, *quantum defect* (*Rydberg correction).*

2. The N-electron Hamiltonian for the principal structure of many-electron atoms:

$$\mathcal{H}=\sum_{i=1}^{N}\left(-\frac{\hbar^2}{2m_e}\nabla_i^2-\frac{Ze^2}{4\pi\varepsilon_0 r}\right)+\frac{1}{2}\sum_{i,j}^{N}{}'\frac{e^2}{4\pi\varepsilon_0 r_{ij}}.$$

3. The central field Hamiltonian

$$\mathcal{H}_{\mathrm{CF}} \equiv \sum_{i=1}^{N} \left(-\frac{\hbar^2}{2m_e} \nabla_i^2 + \mathcal{V}_{\mathrm{CF}}(r_i) \right),$$

with the central field given by

$$\mathcal{V}_{\mathrm{CF}}(r_i) = -\frac{Ze^2}{4\pi\varepsilon_0 r_i} + \mathcal{V}_{\mathrm{scr}}(r_i) = -\frac{e^2}{4\pi\varepsilon_0} \frac{Z_{\mathrm{eff}}(r_i)}{r_i}.$$

4. Notation: The sum over all *different* pairs with $i, j \in \{1, \cdots N\}$ can be written in two equivalent ways:

$$\tfrac{1}{2} \sum_{i,j=1}^{N}{}' \equiv \sum_{i>j}^{N},$$

where the prime indicates the exclusion of the terms $i = j$ and the factor $\frac{1}{2}$ has to be included to correct for double counting. Alternatively, on can sum over all pairs with $i > j$.

9 Many-electron wavefunctions

Chapter 9 is a formal intermezzo in between the other chapters. It is important because it serves to understand why a many-electron problem can remain manageable. We develop the toolbox for fermionic many-body systems. We have another good look at the notion *exchange* as well as the *lifting of exchange degeneracy* by *Coulomb repulsion* between the electrons. We start the chapter by introducing the *exchange operator* $\mathcal{P}$ and come to the conclusion that this is an *observable* with *eigenvalues* ±1 corresponding to symmetric (+1) or antisymmetric (−1) eigenstates. Identical particles turn out to show *only one* of these eigenvalues. Depending on this eigenvalue they are called *bosons* (+1) or *fermions* (−1). The consequence of the antisymmetry of the wavefunction is that two fermions cannot occupy the same states. The electrons are fermions and this becomes manifest in the form of the *Pauli principle.*

The many-electron states can be written as *Slater determinants.* This means that we should be able to evaluate the expectation values of operators sandwiched between two Slater determinants. For instance: what is the angular momentum of such a state? We show that matrix elements in which an operator is sandwiched between two Slater determinants always can be reduced to relative simple expressions. In principle such a N-body matrix element can be written as a sum of $N! \times N!$ terms but, fortunately, most of these are zero and the remaining terms equal to each other (or to a manageable number of characteristic values). For *one-body operators* these are expressions in which only one-body matrix elements appear which can take at most N different values. For *two-body operators* these are expressions of at most $N(N-1)$ terms in which only matrix elements of pair states appear, which are either equal to a “direct” value or to an “exchange” value.

To study at home:

§ 9.1: Study the definition of the exchange operator $\mathcal{P}$ and understand that this is an *observable* with eigenvalues ±1. Note that $\mathcal{P}$ commutes with the Hamiltonian and that the joint basis consists of symmetric (+1) and antisymmetric (−1) eigenstates of the Hamiltonian. We arrive at the (empirical) conclusion that two identical particles always occupy only one of the eigenstates of the exchange operator. Depending on the eigenvalue they are called bosons (+1) or fermions (−1).

§ 9.1.1: Experimentally the electrons turn out to be fermions. The consequence of the antisymmetry of the wavefunction is that two fermions cannot occupy the same state (Pauli exclusion principle). Study the consequence of the presence of spin: if the orbital wavefunction is symmetric the spin state has to be antisymmetric (or vice versa) to assure that the total pair state is antisymmetric under exchange of particles with spin..

§ 9.1.2: Note the definition of *spinorbital*s. Verify that a *two-electron* state can always be written as a linear combination of at most two 2×2 determinants, so-called *Slater determinants.* Convince yourself that the concept of the Slater determinant can be generalized to a $n \times n$ determinant for n fermions. Beware of the difference between the *exchange operator* $\mathcal{P}$ and the *permutation operator* P,

$$\psi_\alpha\left(\mathbf{r}_1,\sigma_1;\cdots;\mathbf{r}_N,\sigma_N\right)=\sqrt{\frac{1}{N!}}\begin{vmatrix}\varphi_{\alpha_1}\left(\mathbf{r}_1,\sigma_1\right) & \cdots & \varphi_{\alpha_N}\left(\mathbf{r}_1,\sigma_1\right)\\ \vdots & \dots & \vdots\\ \varphi_{\alpha_1}\left(\mathbf{r}_N,\sigma_N\right) & \cdots & \varphi_{\alpha_N}\left(\mathbf{r}_N,\sigma_N\right)\end{vmatrix}.$$

The *Slater determinant* is the simplest generalization of the product wavefunction . It has the proper permutation symmetry and is consistent with the Pauli principle. In the Dirac notation this state takes the form

$$|\psi_\alpha\rangle \equiv |\alpha_1,\cdots,\alpha_N\rangle \equiv \sqrt{\frac{1}{N!}}\sum_P(-1)^p P|\alpha_1,\cdots\alpha_N),$$

where

$$|\alpha_1, \cdots \alpha_N) \equiv |\alpha_1\rangle_1 |\alpha_2\rangle_2 \cdots |\alpha_N\rangle_N \equiv |\psi_\alpha) \tag{P.4}$$

is the N-body ordered product state of one-body states $|\alpha_\kappa\rangle_i$, in which $\kappa \in \{1, \cdots, N\}$ is called the *state index* and $i \in \{1, \cdots, N\}$ the *particle index*. Make sure that that you have a good understanding of the Slater determinant in both notations, in particular the difference between the notations $|\rangle$ and $|)$ used for *symmetrized* and *unsymmetrized* many-body states, respectively.

§ 9.1.3: A compact notation is essential to maintain the overview. Make sure that you understand the Dirac notation $|1, \bar{1}, 0, \bar{0}, -1, -\bar{1}\rangle_{2p^6}$, where we use the *standard ordering convention*: high M_L before low M_L and „spin up" before „spin down". For closed shells only a *single* state is consistent with the Pauli principle. Convince yourself that for a nl^x configuration every electron can be found in one of $\nu = 2(2l+1)$ states $|nlm_l s m_s\rangle$. For the same configuration we can identify ν^2 possible pair states, $\binom{\nu}{x}$ of which satisfy the Pauli principle. An interesting property of Slater determinants is that they are invariant under unitary transformation (see Problem 9.4).

§ 9.2: Once we have many-electron states we turn to evaluating matrix elements. It may seem a tough task to evaluate many-body operators sandwiched between determinantal wavefunctions but this will turn out manageable.

§ 9.2.1: We start with *one-body operators*.

1. These are zero if the matrix elements differ in *more* than *one* pair of spinorbitals.
2. Study the description of *off-diagonal* matrix elements differing in *one* pair of spinorbitals. Make sure that you understand why most of the terms are again zero. It turns out that $N(N-1)! = N!$ terms are nonzero and these are all equal to each other.
3. Study next the diagonal matrix elements. Again $N!$ terms are nonzero. This time we group them in N sets of $(N-1)!$ terms with the same value; i.e., N different terms are possible.

§ 9.2.2: Next we turn to *two-body operators*.

1. These are zero if the matrix elements differ in *more* than *two* pairs of spinorbitals.
2. Study the description of *off-diagonal* matrix elements differing in *two* pairs of spinorbitals. Make sure that you understand why most of the terms are again zero. It turns out that $\frac{1}{2}N(N-1)[2(N-2)!] = N!$ terms are nonzero; $\frac{1}{2}N(N-1)$ of these are called the "direct" terms (all equal to each other) and the other $\frac{1}{2}N(N-1)$ are the "exchange" terms (also all equal to each other).
3. Study the description of *off-diagonal* matrix element differing in *one* pair of spinorbitals. We group them in N sets of $(N-1)!$ terms, half of them carrying a "direct" value and half of them an "exchange" value; i.e., in this case N different values can occur.
4. Next come the diagonal matrix elements. We group them in $N(N-1)$ sets of $(N-2)!$ terms. Half of these carry a "direct" value and the other half an "exchange" value; i.e., in this case $N(N-1)$ different values can occur.

   Problem 9.5 is important. It shows that exchange *never* contributes to *spin-independent* two-body interactions between *paired* spins This knowledge will come out handy.

§ 9.3: (*optional*) In this section we introduce the *occupation number representation* (also called second quantization).

§ 9.3.1: (*optional*) It forms the (non-relativistic) onset to a quantum field theory for the atom. You have to get used to it but one this is done you will realize that the many-body formalism simplifies to an algebra with simple and intuitive rules. This is no luxury because the formalism of § 9.2 (with all cases to be distinguished) is labor intensive and error prawn. In the *occupation number representation* the emphasis is on the operators rather than on the states. The operators are be expressed in terms of so-called *construction operators*, either *creation operators* or *annihilation operators*. These represent a generalization of the shift operators introduced for angular momentum. The construction operators serve to create any desirable atomic state by creation or annihilation of spinorbitals in the atom. § 9.3 is *highly recommended* but falls *outside the exam*.

§ 9.3.2: (*optional*) We start with the definition of a new representation: the *occupation number representation* in the N-body Hilbert space. In this representation we specify the occupation of all possible states (most of them are empty). In our case (for many-electron states) we specify the occupation of the spinorbitals. These states are called *number states*. It is just another way to specify the Slater determinants. The N-electron Slater determinant $|\psi_\gamma\rangle$ is written as $|\psi_\gamma\rangle \equiv |n_1, n_2, \cdots\rangle$, where $n_s \in \{0, 1\}$ is the occupation number of the spinorbital $|\alpha_s\rangle$, with $n_r + n_s + \cdots + n_t = N$.

§ 9.3.3: (*optional*) We next extend the Hilbert space into a *Grand Hilbert space* (Fock space) in which the states may consist of any number of particles. The number states from the previous section turn out to be the eigenstates of the *number operators* $\hat{n}_1, \hat{n}_2, \cdots$, with *occupation numbers* $n_1, n_2, \cdots$ as the eigenvalues,

$$\hat{n}_s |n_1, n_2, \cdots, n_s, \cdots\rangle = n_s |n_1, n_2, \cdots, n_s, \cdots\rangle,$$

where $n_1, n_2, \cdots$ can take the values 0 or 1 (for fermions). The eigenstates $|n_1, n_2, \cdots, n_s, \cdots\rangle$ form a basis of the *occupation number representation*. In this representation every operator can be expressed in terms of the elementary operators $\hat{a}_s^\dagger$ (the *creation* operator for the spinorbital $|\alpha_s\rangle$) en $\hat{a}_s$ (the *annihilation* operator for the spinorbital $|\alpha_s\rangle$),

$$\begin{aligned} \hat{a}_s^\dagger |n_s, \cdots\rangle &\equiv \sqrt{n_s + 1}\, |n_s + 1, \cdots\rangle \\ \hat{a}_s |n_s, \cdots\rangle &\equiv \sqrt{n_s}\, |n_s - 1, \cdots\rangle, \end{aligned}$$

with $n_s \in \{0, 1\}$. By imposing the anti-commutation relations,

$$\hat{a}_r, \hat{a}_s^\dagger\} = \delta_{rs} \;; \qquad \{\hat{a}_r, \hat{a}_s\} = \{\hat{a}_r^\dagger, \hat{a}_s^\dagger\} = 0,$$

we assure that the Pauli principle remains satisfied. This is demonstrated with seven examples. The commutation relations derived in Problem 9.6 are very valuable.

§ 9.3.4: (*optional*) After the preparatory work we can rewrite the one- and two-body operators in the the *occupation number representation*,

$$Q_1 = \sum_i q_i \quad \rightarrow \quad \hat{Q}_1 = \sum_{s,s'} \langle s'|q|s\rangle \hat{a}_{s'}^\dagger \hat{a}_s,$$

where the sum in the expression for Q_1 runs over the *particle index* and the sum in the expression for $\hat{Q}_1$ runs over the *state index* of all spinorbitals (occupied or not) and $\hat{a}_s^\dagger$ en $\hat{a}_s$ are the construction operators by which the occupation of the state $|\alpha_s\rangle$ can be changed. Likewise, we find for the two-body operators

$$Q_2 = \tfrac{1}{2} \sum_{i,j}{}' q_{ij} \quad \rightarrow \quad \hat{Q}_2 = \tfrac{1}{2} \sum_{t,t'} \sum_{s,s'} (s', t'|q_{12}|s, t)\, \hat{a}_{s'}^\dagger \hat{a}_{t'}^\dagger \hat{a}_t \hat{a}_s,$$

where $(s', t'|q_{12}|s, t)$ contains *unsymmetrized* two-body states. In the remainder of § 9.3.4 we show that these two operators do exactly what we want, in particular all cases of § 9.2 are reproduced.

§ 9.4: We now return to the main body of the text. We apply the many-body formalism to angular momentum operators. In particular it will enable us to calculate the angular momentum properties of Slater determinants.

§ 9.4.1: In this section we investigate the action of the operators L_z, $L_\pm$ en $\mathbf{L}^2$ (of the total orbital angular momentum) on Slater determinants. The spin orbitals are denoted by $|\alpha_k\rangle = |n^k l^k m_l^k s^k m_s^k\rangle$. Here the total orbital angular momentum is defined as

$$\mathbf{L} = \sum_{i=1}^{N} \boldsymbol{l}_i, \tag{P.5}$$

where $\boldsymbol{l}_i$ is the orbital angular momentum of electron$i$.

Convince yourself that

$$L_z|\psi_\alpha\rangle = \sum_{k=1}^{N} m_l^k \hbar\,|\psi_\alpha\rangle = M_L^\alpha \hbar\,|\psi_\alpha\rangle,$$

just as we would write intuitively...

Convince yourself that

$$L_\pm|\psi_\alpha\rangle = \sum_{k=1}^{N} \sqrt{l^k(l^k+1) - m_l^k(m_l^k \pm 1)}\hbar\,|\psi_\alpha(m_l^k \pm 1)\rangle,$$

which is already less intuitive.

Next comes the case

$$\mathbf{L}^2|\psi_\alpha\rangle = \left\{ \sum_{k=1}^{N} l^k(l^k+1) + \sum_{k,k'=1}^{N}{}' m_l^k m_l^{k'} \right\} \hbar^2\,|\psi_\alpha\rangle +$$

$$+ \sum_{k,k'=1}^{N}{}' \sqrt{l^k(l^k+1) - m_l^k(m_l^k+1)}\sqrt{l^{k'}(l^{k'}+1) - m_l^{k'}(m_l^{k'}-1)}\hbar^2\,|\psi_\alpha(m_l^k{+}1)(m_l^{k'}{-}1)\rangle.$$

Here we come not far with intuition and the efforts for§ 9.2 are rewarded.

Study the Problems 9.7 and 9.8 and come to the conclusion that for *stretched* orbital angular momentum also the expression $\mathbf{L}^2$ becomes intuitive. Note the commutation relations (9.106). The derivation is given in Problems 9.9 and 9.10 but is *not* part of the exam.

§ 9.4.2: Study how the expressions simply a bit for the case of spin because $s = 1/2$ for all electrons (in contrast the value of l can vary).

§ 9.4.3: Note that l_i^2 of the individual electron commutes both with $\mathbf{J}^2$ and with $\mathbf{L}\cdot\mathbf{S}$, where $\mathbf{J} = \mathbf{L} + \mathbf{S}$.

Minimum knowledge:

1. The compact notations: *helium*:

$$|\psi_{\mathrm{He}}\rangle = |1s, 1\bar{s}\rangle \equiv |0, \bar{0}\rangle_{1s^2} \equiv |\upharpoonleft\!\downharpoonright\rangle_{1s^2},$$

beryllium:

$$|\psi_{\mathrm{Be}}\rangle = |1s, 1\bar{s}, 2s, 2\bar{s}\rangle \equiv |(0,\bar{0})_{1s^2}(0,\bar{0})_{2s^2}\rangle \equiv |(\upharpoonleft\!\downharpoonright)_{1s^2}(\upharpoonleft\!\downharpoonright)_{2s^2}\rangle,$$

neon:

$$\begin{aligned} |\psi_{\mathrm{Ne}}\rangle &= |1s, 1\bar{s}; 2s, 2\bar{s}; 2p_1, 2\bar{p}_1, 2p_0, 2\bar{p}_0, 2p_{-1}, 2\bar{p}_{-1}\rangle \\ &= |(0,\bar{0})_{1s^2}(0,\bar{0})_{2s^2}(1,\bar{1},0,\bar{0},-1,-\bar{1})_{2p^6}\rangle \equiv |(\upharpoonleft\!\downharpoonright)_{1s^2}(\upharpoonleft\!\downharpoonright)_{2s^2}(\upharpoonleft\!\downharpoonright\ \upharpoonleft\!\downharpoonright\ \upharpoonleft\!\downharpoonright)_{2p^6}\rangle. \end{aligned}$$

2. The expression
$$L_z|\psi_\alpha\rangle = \sum_{k=1}^{N} m_l^k \hbar \, |\psi_\alpha\rangle,$$
and its analogue for spin angular momentum.

3. The expression
$$L_\pm|\psi_\alpha\rangle = \sum_{k=1}^{N} \sqrt{l^k(l^k+1) - m_l^k(m_l^k \pm 1)}\hbar \, |\psi_\alpha(m_l^k \pm 1)\rangle,$$
and its analogue for spin angular momentum.

4. The expression
$$\mathbf{L}^2|\psi_\alpha^{ll}\rangle = Nl(Nl+1)\hbar^2|\psi_\alpha^{ll}\rangle$$
for $\mathbf{L}^2$ in the case of stretched orbital momentum (and its analogue for spin). Beware that this expression is *completely wrong* in case the angular momentum is not stretched.

10 Ground states of many-electron atoms - part 1

All ground work has been done to understand the periodic system of Mendeleev. This table provides the ground states of many-electron atoms. The theoretical underpinning of the periodic system is called the *Aufbau principle.* The electrons are grouped in *shells* en *subshells.* The electrons in a subshell (often simply called shells) share the same radial wavefunction and are called *equivalent.* The degeneracy of electron states (including spin) determines how many electrons fit in a given subshell. The maximum number is determined by the *Pauli principle.* The distribution over the shells is called the *electron configuration.* A shell with the maximum number of electrons is called a *full shell* or *closed shell.* A vacant electron in a shell is called a *hole.* The electrons outside closed shells are called *valence electrons.* The electrons in closed shells are called *core electrons.* Chapter 10 start by simply stating the *Hund rules* for the determination of the electronic ground state. The Hund rules have no exact validity but are ideally suited to understand the physics underpinning the Aufbau principle. For this reason the form the guiding thoughts through this important chapter.

To study at home:

Read the introduction. Understand that the ground state of the atom is determined by the Coulomb repulsion between the occupied spinorbitals.

§ 10.1: Read the Hund rules.

§ 10.2: Coulomb integrals and Hartree-Fock method.

§ 10.2.1: In this section we make a start with the calculation of the energy of the ground state. In calculating the Coulomb repulsion we recognize three contributions: (a) repulsion between two electrons from closed shells; (b) the repulsion between a valence electron and a core electron; (c) The repulsion between two valence electrons. It turns out that the repulsion of a nlm_lsm_s electron by the electrons from a filled $n'l'$ shell does not depend on the values of m_l en m_s. In other words, two *equivalent* electrons always experience the same Coulomb repulsion by a closed shell. Therefore, *only* the *valence* electrons determine which state has the lowest energy.

§ 10.2.2: Note that sometimes more than a single electron configuration is relevant. If two configurations have approximately the same energy the become mixed as follows from second-order perturbation theory.

§ 10.2.3: (*optional*) The approach of § 10.2.1 can be underpinned by a variational procedure, the Hartree-Fock method. This method strongly resembles the Hartree method but is based on Slater determinants. In this way it inherently satisfies the Pauli principle. Note the relation to *ferromagnetic exchange.* In view of the importance of the Hartree-Fock method in theoretical physics we derive the Hartree-Fock equations but *this procedure is not part of the exam.*

§ 10.2.4: (*optional*) If you have digested the Hartree-Fock method you will also enjoy Koopmans' theorem. This theorem enables us to determine the quality of the Hartree-Fock approximation by measuring the photo-emission of core electrons.

§ 10.2.5: (*optional*) If you have digested the Hartree-Fock method you will also enjoy the Slater approximation. This approximation provides some physical insight in the role of the Coulomb integrals.

§ 10.2.6: This section is part of the exam. It is the important follow up on section§ 10.2.1 and connects to our discussion of helium-like atoms. The Coulomb integrals can be separated into terms representing the Coulomb repulsion *within* the shells (*intra-shell*) and terms for the Coulomb repulsion *between* the shells (*inter-shell*). Make sure that you understand how these contributions can be calculated with the methods of Chapter 7. Problem10.1 is instructive because it demonstrates the interaction energy between a *valence* electron and a *closed shell* does *not* depend on the magnetic quantum number of that electron.

§ 10.3: First we discuss spherical atoms; i.e., atoms *without* orbital angular momentum.

§ 10.3.1: For *closed shells* both the *total orbital angular momentum* and the *total spin* are zero (convince yourself). Study *Unsöld's theorem*: Full or half-filled shells are spherical. Study Fig. 10.2: note that for closed shells the electron affinity vanishes. Furthermore, study the difference in ionization energy between small closed shells (ns^2), the alkaline-earth elements, and larger closed shells (np^2 en nd^2). Note that the ionization energy increases with the number of electrons in a closed shell. Make sure that you understand this phenomenon. In the inert gases Ne en Ar both the s shell and the p shell are closed; in Kr and Xe this holds for the s shell, the p shell and the d shell; in Rn the s shell, the p shell, the d shell and the f shell are closed. In the latter case it has become most unfavorable to pull an electron from the shells.

§ 10.3.2: For a *half-filled* shells the spin state is stretched. Convince yourself that the orbital angular momentum has to be zero in this case.

§ 10.4: Next the atoms with *one* valence electron.

§ 10.4.1: The screening of the nuclear charge is smaller for s electrons than for electrons with $l > 0$. Understand why this is the case and why this gives rise to preferential filling of the $4s$ shell before the $3d$ shell, the $5s$ shell before the $4d$ and $4f$ shells, etc., and why the binding advantage of the s shells becomes marginal for almost half-filled or almost filled shells (read the text on the collapse of the d shell). Understand the reference to *configuration interaction* in this context. In this section we return to the discussion of screening in alkali-like atoms for increasing nuclear charge and how this gives rise to pulling a hole in the $4s$ shell. This is an interesting anomaly in filling of the $3d$ shell in the fourth period of the periodic system.

§ 10.4.2: We discuss how exchange affects the charge distribution of the core electrons. The keyword is *core polarization* as a result of quantum correlations. If you like you can understand here why core polarization can give rise to a Fermi contact interaction in cases where you would not expect it. And how this can give rise to a *negative* hyperfine coefficient for *positive* gyromagnetic ratio ($\gamma_I > 0$). This feature explains the level inversion in lithium (see Fig. 5.3) which is called anomalous because it cannot be explained by the elementary theory for hydrogen like atoms.

§ 10.5: The labor starts for atoms with *more than one* valence electron (and *without* spin-orbit coupling). This case calls for understanding of Hund's rules 1 and 2.

§ 10.5.1: Read the intro.

§ 10.5.2: First of all we study a partially filled shell with two equivalent p electrons. Verify that without Pauli exclusion $(2l+1)(2s+1) \times (2l+1)(2s+1) = 6 \times 6 = 36$ basis states are possible for such a pair, $\binom{6}{2} = 15$ of which are consistent with the Pauli principle. These are the 15 Slater determinants from the upper part of Table 10.2. The 36 states can also be represented by 36 LS terms of the coupled representation (lower part of Table 10.2; coupling into states of total L and total S). Three questions emerge: a.) which of these LS terms are consistent with the Pauli principle? b.) what is the relation between the LS terms and the Slater determinants? c.) which term has the lowest energy?

a.) Study the decision table 10.3. It is used to determine which LS terms are consistent with the Pauli principle. Only *one* triplet and two singlets this turns out to be the case. According to the Hund rules the only triplet has to be the ground state.

- **b.)** For stretched states the LS term can be expressed as a single Slater determinant. If the LS term is not stretched it can be expressed as a linear combination of Slater determinants. The actual linear combination can be determined by operating $L_\pm$ or $S_\pm$ onto a stretched state. Sometimes these operators have to be applied more than once. Study how, starting from the LS terms $|^3P;1,1\rangle$ and $|^1D;2,0\rangle$, we derive two *orthonormal* linear combinations of Slater determinants. Since we are dealing with a 3D subspace the third linear combination (for $|^1S;0,0\rangle$) has to be orthogonal to both of the other states. With this canonical procedure we can express every LS term as a linear combination of Slater determinants.
- **c.)** Once we have expressed our LS terms as a linear combination of Slater determinants be can also calculate their energy. For this we use the expressions for matrix elements of one- or two-body operators and the Coulomb integrals from Chapter 7.. Because the canonical procedure can be labor intensive the Slater sum rule comes out handy. This rule is based on the preservation of the trace of a matrix under unitary transformation. This can eliminate the use of the orthonormalization procedure. Once we have the energies it turns out that the *first Hund rule is satisfied.* This demonstrates that the electrostatic repulsion between the valence electrons determines the ground state.

§ 10.5.3: Next we turn to a partially filled shell with two equivalent d electrons. Verify that without Pauli exclusion $(2l+1)(2s+1)\times(2l+1)(2s+1)=10\times 10=100$ basis states are possible for such a pair, $\binom{10}{2}=45$of which are consistent with the Pauli principle. These are the 45 Slater determinants from Table 10.6. The 100 states can also be represented by 100 LS terms of the coupled representation (lower part of Table 10.6). The three questions return: a.) which of these LS terms are consistent with the Pauli principle? b.) what is the relation between the LS terms and the Slater determinants? c.) which term has the lowest energy?

- **a.)** Study the decision table 10.7). It is used to determine which LS terms are consistent with the Pauli principle. For *two* triplets and *three* singlet this turns out to be the case turns out to be Pauli consistent. According to the Hund rules, one of the two triplets (^3F and ^3P) has to be the ground state, but which?
- **b.)** For stretched states the LS term can be expressed as a single Slater determinant. Holds for the ^3F term and we can write down an expression for the Coulomb repulsion in this term. Study how the Coulomb repulsion in the ^3P term is calculated by using the Slater sum rule.
- **c.)** We calculate the Coulomb repulsion for the ^3F and ^3P terms, using the Coulomb integrals from Chapter 7. The repulsion turns out to be smallest for the ^3F term. This is the term with the largest value of L. This result *confirms the second Hund rule.* It demonstrates that, also for the second Hund rule, the electrostatic repulsion between the valence electrons determines the ground state.

Minimum knowledge:

1. You should be able to determine the electron configurations of the ground states of all elements up to *krypton* (Kr).
2. You should be able to explain the preferential occupation of the s shells as well as the anomalies occurring for *chromium* (Cr) and *Copper* (Cu).
3. The three Hund rules.
4. You should be able to determine all LS terms for a given electron configuration.

5. You should be able to determine for a given electron configuration all Slater determinants consistent with the Pauli principle (decision tables).
6. You should be able to use the operators $L_{\pm}$ of $S_{\pm}$ on LS terms and on Slater determinants.
7. You should be able to express the electrostatic energy of an LS term in terms of the Coulomb integrals for pair states
8. You should be able to use the Slater sum rule.

10 Ground states of many-electron atoms - part 2

The third Hund's rule discriminates between states with the same values of L en S but differing in J. The rule depends on the filling of the shell (less-than-half-filled versus more-than-half-filled). To understand the foundation of this rule we evaluate the spin-orbit interaction in many-electron atoms. We discover that a more-than-half-filled shell can be analyzed as a full shell with some holes. Such a hole has a positive charge which switches the sign of the spin-orbit coupling strength; i.e., $\xi(r)$ becomes negative (see Section 4.6.1). This manifests itself in so-called inverted level ordering when changing from less-than-half-filled shells to more-than-half-filled shells. Once we understand also the third Hund's rule we can determine the J value of state of lowest energy for a given electron configuration (for LS coupling).

§ 10.6: Fine structure in many-electron atoms - Hund's rule 3.

§ 10.6.1: Study how the Zeeman Hamiltonian for N electrons with orbital angular momentum $\boldsymbol{l}_i$ and spin $\boldsymbol{s}_i$ can be rewritten in the form of an effective Zeeman Hamiltonian of *one* particle with orbital angular momentum $\mathbf{L} = \sum_i \boldsymbol{l}_i$ and spin $\mathbf{S} = \sum_i \boldsymbol{s}_i$.

§ 10.6.2: The spin-orbit coupling of one electron, $\xi(r)\boldsymbol{l} \cdot \boldsymbol{s}$, can be calculated as in the case of hydrogen but with the Coulomb potential of the nucleus replaced by a screened Coulomb potential. Convince yourself that the coupling constant will increase with the nuclear charge.

§ 10.6.3: As long as the exchange dominates over the spin-orbit coupling (this is the case for small to moderate nuclear charge) the orbital angular momenta first couple into a total orbital angular momentum $\mathbf{L} = \sum_i \boldsymbol{l}_i$ and the spin angular momenta into a total spin $\mathbf{S} = \sum_i \boldsymbol{s}_i$. Subsequently, $\mathbf{L}$ and $\mathbf{S}$ couple into the total angular momentum $\mathbf{J} = \mathbf{L} + \mathbf{S}$. The $\mathbf{J}$ is conserved in zero field (neglecting hyperfine structure). This coupling scheme is called LS coupling or *Russell-Saunders coupling.* In atoms with large nuclear charge the spin-orbit coupling dominates over the exchange first couple $\boldsymbol{l}_i$ and $\boldsymbol{s}_i$ into $\boldsymbol{j}_i = \boldsymbol{l}_i + \boldsymbol{s}_i$. Subsequently, the $\boldsymbol{j}_i$ couple into the total angular momentum $\mathbf{J} = \boldsymbol{j}_1 + \cdots \boldsymbol{j}_N$, again the conserved quantity. This type of coupling is called jj coupling.

§ 10.6.4: In the lectures we restrict ourselves to LS coupling because this applies to most not too heavy atoms. It turns out that the LS coupled Hamiltonian can be rewritten in the form of an effective one-body Hamiltonian for a particle with orbital angular momentum $\mathbf{L} = \sum_i \boldsymbol{l}_i$ and spin $\mathbf{S} = \sum_i \boldsymbol{s}_i$. What remains to be done is calculate the matrix element of the spin-orbit coupling. Study how this spin-orbit shift is obtained sing the Wigner-Eckart theorem,

$$\Delta E_{n,J}^{LS} = \left(\zeta_{nLS}/\hbar^2\right) \langle LSJM_J|\mathbf{L} \cdot \mathbf{S}|LSJM_J\rangle,$$

where

$$\zeta_{nLS} = \zeta_{nl} \sum_i \langle L||l_i||L\rangle\langle S||s_i||S\rangle,$$

is called the the Russell-Saunders coupling constant
With all this the Hamiltonian is reduced to an effective one-body Hamiltonian. As a consequence the phenomenology of the many-electron atoms is very similar to that of hydrogen-like atoms, be it that the spin S is not necessarily $1/2$ but can take an arbitrary value.

§ 10.6.5: Study why an electron shell with a vacancy behaves like a closed shell with a hole. Such a hole has a positive charge, a negative mass and an intrinsic magnetic moment opposite to that of the electron which fits the hole. Electron and hole always coincide and have the same velocity but opposite orbital momentum. Study the add/subtract procedure by which we can show that the spin-orbit coupling constant ζ_{nl} of a single hole (*i.e.*, a closed shell with one vacancy) is negative.

§ 10.6.6: What remains to be done is calculate the spin-orbit shift using the **L** and **S** values following from following from Hund's rule 1 en 2 for an arbitrary nl^x configuration. Because this state can be can be represented by a single Slater determinant we can do this calculation in two ways. First we sum the one-electron contributions using Eq. (9.44) and obtain an expression which is proportional to the one-electron coupling constant ζ_{nl},

$$\Delta E^{LS}_{n,J_{\max}} = \zeta_{nl} \sum_{\kappa=1}^{x} m_l^{\kappa} m_s^{\kappa},$$

with $M_S = \sum_{\kappa=1}^{x} m_s^{\kappa} = S$ and $M_L = \sum_{\kappa=1}^{x} m_l^{\kappa} = L$ for the stretched state.
Next we compare this result with the expression obtained with the effective Hamiltonian; i.e., proportional to ζ_{nLS}. The result turns out to depend on the filling of the shell. For a *less-than-half-filled* shell $(0 < x < 2l + 1)$ we obtain for the many-electron coupling constant $\zeta_{nLS} = \zeta_{nl}/2S$; For *more-than-half-filled* shells $(2l + 1 < x < 2(2l + 1))$ we obtain $\zeta_{nLS} = -\zeta_{nl}/2S$. Note that the denominator $2S$ can be interpreted as the number of *electrons* in a *less-than-half-filled* shell and as the number of *holes* in a *more-than-half-filled* shell. Make sure that you understand how to derive from the fine structure diagram whether the shell is less or more than half (see also Fig. 10.9). Note that Hund's rule 3 plays no role for half filled shells because in this case only a single value is possible for J $(J = S)$.
This concludes the underpinning of the *third Hund rule* as the result of a *spin-orbit shift*.

§ 10.8: The section on jj coupling is *not part of the exam*.

Minimum knowledge:

1. The Hund rules
2. The equivalence of electrons and holes, in particular the properties of holes: positive charge, negative mass, velocity equal (momentum opposite) to the electron that fits the hole and an intrinsic magnetic moment opposite to that of the electron that fits the hole.
3. The Slater determinant of the fully stretched state obtained by applying Hund's rule 1 en 2.
4. The expression for the spin-orbit shift:

$$\Delta E^{LS}_{n,J} = \left(\zeta_{nLS}/\hbar^2\right) \langle nLSJM_J|\mathbf{L}\cdot\mathbf{S}|nLSJM_J\rangle.$$

5. The Hund's rule 3 relations

$$\zeta_{nLS} = +\frac{\zeta_{nl}}{2S} \text{ for } 0 < x < 2l + 1$$
$$\zeta_{nLS} = -\frac{\zeta_{nl}}{2S} \text{ for } 2l + 1 < x < 2(2l + 1)$$

   for the spin-orbit coupling constants of a *less*-than-half-filled shell, $0 < x < 2l + 1$, for a *more*-than-half-filled shell, $2l + 1 < x < 2(2l + 1)$.

6. Last but not least: make sure that you can determine the ground state of an arbitrary atom starting from its electron configuration.

H Time-independent perturbation theory (optional)

Perturbation theory is unfortunately a rather dry subject. However, it is essential for the proper understanding of the rest of the lectures. Hence, a full lecture is dedicated to this subject which offers you the opportunity to deal with time-independent perturbation theory - once and for all. We meet the concept of *the perturbation* as a perturbing term added to a *well-known* Hamiltonian; i.e., a Hamiltonian for which the energy levels and eigenstates are known. We have to distinguish between perturbation theory of *non-degenerate* and that of *degenerate* levels. The theory holds in the limit of *weak* perturbations; i.e., perturbations which hardly modify the wavefunctions and for which the energy shifts remain small. The case of a *non-degenerate level* is simple: the energy *levels shift* a little bit. However, in atomic physics we are almost always dealing with *degenerate levels*, which is more difficult because the sublevels may shift differently. This results in *level splitting* (lifting of degeneracy). Fortunately, in many cases we can deal with degeneracy by treating the sublevels as non-degenerate levels. This is called reduction of the theory for degenerate levels to “ordinary” perturbation theory, *i.e.*, to perturbation theory of nondegenerate levels. This reduction is always possible *if the perturbation commutes with the Hamiltonian.* Fortunately this is often the case in atomic physics (if not rigorously, at least to sufficiently good approximation). Then, by *using the joint basis* of unperturbed Hamiltonian and perturbation the calculation is greatly simplified.

To study at home

§ H.1: In this introductory section we meet the concepts of *unperturbed Hamiltonian* $\mathcal{H}_0$ and *perturbation* $\mathcal{H}_1$. We define representations $\{|\psi_n\rangle\}$ of the full Hamiltonian $\mathcal{H} = \mathcal{H}_0 + \mathcal{H}_1$ and $\{|\phi_n\rangle\}$ of the unperturbed Hamiltonian $\mathcal{H}_0$ and derive an expression for the level shift as a result of the perturbation $\mathcal{H}_1$.

§ H.2: *Perturbation theory of a non-degenerate level.* We parameterize the Hamiltonian by introducing the perturbation parameter λ. We introduce the perturbed states $|\psi_n(\lambda)\rangle$ with corresponding perturbation coefficients $a_\nu(\lambda) \equiv \langle\phi_\nu|\psi_n(\lambda)\rangle$. In the *Ansatz* we express the perturbed state $|\psi_n(\lambda)\rangle$ as a series in powers λ^p, where the states $|\psi_n^p\rangle$ (with corresponding coefficients $a_\nu^{(p)} = \langle\phi_\nu|\psi_n^p\rangle$) represent a correction (to be determined) onto the unperturbed state $|\psi_n^0\rangle \equiv |\phi_n\rangle$. We obtain an expression for the normalization of the perturbed states. It turns out that the normalization is only conserved in the perturbation expansion if the coefficients a_ν^p satisfy certain requirements. We derive an expression for the level shift in the form of a series in powers λ^p. In this way we find the contributions to the level shift order by order.

1. *Zeroth order.* This is the energy of the unperturbed state.
2. *First order.* The first-order correction *of the energy* is obtained by “sandwiching” the perturbation between unperturbed states,

$$\Delta E_n^{(1)} = \langle\phi_n|\,\mathcal{H}_1\,|\phi_n\rangle\,.$$

   With this result the first-order correction of the *state* can be calculated,

$$|\psi_n^1\rangle = \sum_{\substack{m\\ m\neq n}} \frac{\mathcal{H}_1\,|\phi_n\rangle}{E_n^0 - E_m^0}.$$

3. *Second order.* The second-order correction *of the energy* is obtained with the aid of the first-order correction *of the state*,

$$\Delta E_n^{(2)} = \langle\phi_n|\,\mathcal{H}_1\,|\psi_n^1\rangle = \sum_{\substack{m\\ m\neq n}} \frac{|\,\langle\phi_n|\,\mathcal{H}_1\,|\phi_m\rangle\,|^2}{E_n^0 - E_m^0}.$$

After this we can calculate the second-order correction *of the state.* For non-degenerate levels (*ordinary perturbation theory*) only the calculation of the first- and second-order shifts are part of the exam. The discussion of the third order correction and the concept of *renormalization* of the wavefunction are optional. Beware that these entail non-trivial extensions of the first and second order theory and are interesting to deepen you understanding of perturbation theory.

§ H.3: *Perturbation theory of a degenerate level.* We start in the same way as for non-degenerate levels but already at the level of the *Ansatz* we find that this cannot be done in a unique way. We need *insider knowledge* about the perturbation to formulate the Ansatz in such a way that the perturbation coefficients behave as regular functions of λ. We have to formulate Ansatz in a form consistent with any symmetry breaking by the perturbation. Once this is done we obtain expressions which are very similar to those of "ordinary" perturbation theory; i.e., the perturbation theory of a non-degenerate level.

1. In general it may not immediately obvious how the perturbation breaks the symmetry. This happens for instance in the presence of two competing perturbations. Therefore, it is important to know that starting from an arbitrary unperturbed basis the energy shifts ε with respect to the unperturbed levels can always be obtained by solving a set of coupled equations. This is equivalent to setting the *secular determinant* equal to zero. For a set of k coupled equations this yields a polynomial of power k in the variable ε (called the *characteristic polynomial* of the set of equations - called the *secular equation*). The roots of this polynomial are the eigenvalues corresponding to the energy shifts. The corresponding eigenstates reflect the symmetry of the perturbation. The set of coupled equations can be written as a matrix equation. Solving this set of equations is equivalent to the diagonalization of a matrix (the so called perturbation matrix).

§ H.3.1: This section is of great practical importance. In the special case of a perturbation commuting with the unperturbed Hamiltonian, the perturbation matrix is diagonal when choosing the proper basis. In that basis it is simple to evaluate the perturbation exactly because the exact solution coincides with the first-order expression of "ordinary" perturbation theory. Often the commutation holds only approximately. In such cases the perturbation matrix is only approximately diagonal bur the the first-order expression of ordinary perturbation theory is sufficient to calculate the level shifts. Then, explicit diagonalization is not necessary and this is referred to as a case where the perturbation theory of a degenerate level reduces to ordinary first-order perturbation theory.

§ H.4: *Example: two-dimensional perturbation matrix.* Make sure that you understand the definition of the *coupling angle.* Note that the coupling between the two levels gives rise to *repulsion* of these levels.

§ G.3.4: In this section we discuss the difference between *weak* coupling and *strong* coupling between the levels. Further you should understand that for weak coupling the contribution of off-diagonal matrix elements may be neglected in comparison to that of the diagonal ones (these contribute in higher order).

Minimum knowledge:

1. For time-independent theory the separation of the Hamiltonian in two hermitian parts

$$\mathcal{H} = \mathcal{H}_0 + \mathcal{H}_1.$$

2. For “ordinary” perturbation theory: the formula for the first-order energy shift

   $$\varepsilon_1 = \langle\phi_n|\, \mathcal{H}_1 \,|\phi_n\rangle \,,$$

   where $\{|\phi_n\rangle\}$ is the orthonormal basis corresponding to $\mathcal{H}_0 \,|\phi_n\rangle = E^0 \,|\phi_n\rangle$.

3. For “ordinary” perturbation theory: the formula for the second-order energy shift

   $$\Delta E_n^{(2)} = \langle\phi_n|\, \mathcal{H}_1 \,|\psi_n^1\rangle = \sum_{\substack{m \\ m\neq n}} \frac{|\,\langle\phi_n|\, \mathcal{H}_1 \,|\phi_m\rangle\,|^2}{E_n^0 - E_m^0}$$

4. For perturbation theory of a degenerate level how to solve the secular equation for simple perturbation matrices (*e.g.*, the 2 × 2 case),

   $$\det\left|\mathcal{H}'_{i,j} - \varepsilon_1\delta_{i,j}\right| = 0,$$

   where $\mathcal{H}'_{i,j} = \langle\phi_{n,i}|\, \mathcal{H}_1 \,|\phi_{n,j}\rangle$, with $\{|\phi_{n,i}\rangle\}$, is the basis corresponding to $\mathcal{H}_0 \,|\phi_{n,i}\rangle = E^0 \,|\phi_{n,i}\rangle$

5. In the *weak coupling limit*, the diagonal elements of the perturbation matrix $\mathcal{H}'_{i,j}$ contribute in first order whereas the off-diagonal elements contribute in second order (hence, can be neglected in a first-order calculation). This holds for instance for the Paschen-Back limits of the fine structure and hyperfine structure.

6. Realize that if $\mathcal{H}_0$ and $\mathcal{H}_1$ commute with $\mathcal{H}$ a basis can be found in which the secular determinant is diagonal, which means that the perturbation theory for the degenerate levels has been reduced to “ordinary” first-order perturbation theory.

7. Realize that if $\mathcal{H}_0$ gives rise to degenerate levels that the quantum numbers of those levels are always conserved as long as we restrict ourselves to first-order perturbation theory.

Q

Problem sets 2020

Q.1 Problem set 1

PROBLEMS CHAPTER 1

1. (0.5) Calculate the commutator $\left[r_i, \mathbf{p}^2\right]$ using $[r_i, p_j] = i\hbar\delta_{ij}$ with $i, j \in \{x, y, z\}$. Use in your answer the Einstein notation of implicit summation over repeating indices.

2. (0.5) Prove $\left[L_x, \mathbf{L}^2\right] = 0$ by commutator algebra; *i.e.*, without any specific choice of quantization axis. *Hint:* recall that $[L_x, L_y] = i\hbar L_z$, $[L_y, L_z] = i\hbar L_x$ en $[L_z, L_x] = i\hbar L_y$; *Hint*: $[L_j, L_k] = \varepsilon_{ijk} i\hbar L_i$ (for those who want to practice the Einstein notation)

3. (1.5) Prove the expressions
$$\left(\frac{\partial}{\partial r} + \frac{1}{r}\right)^2 \psi = \left(\frac{\partial^2}{\partial r^2} + \frac{2}{r}\frac{\partial}{\partial r}\right)\psi = \frac{1}{r}\frac{\partial^2}{\partial r^2}(r\psi).$$

4. (1.0) Prove the expression
$$p_r\psi \equiv -\frac{i\hbar}{2}\left[\frac{\mathbf{r}}{r}\cdot\boldsymbol{\nabla} + \boldsymbol{\nabla}\cdot\left(\frac{\mathbf{r}}{r}\right)\right]\psi = -i\hbar\left(\frac{\partial}{\partial r} + \frac{1}{r}\right)\psi.$$
Hint: This expression is valid irrespective of the choice of coordinate system. Most students find it most easy to use spherical coordinates to evaluate the first term within the square brackets and cartesian coordinates to evaluate the second term. Can *you* also derive the second term in spherical coordinates?

5. (4.5) Consider (right-handed) spherical coordinates
$$\begin{aligned}\hat{\mathbf{r}} &= \hat{\mathbf{x}}\sin\theta\cos\phi + \hat{\mathbf{y}}\sin\theta\sin\phi + \hat{\mathbf{z}}\cos\theta \\ \hat{\boldsymbol{\theta}} &= \hat{\mathbf{x}}\cos\theta\cos\phi + \hat{\mathbf{y}}\cos\theta\sin\phi - \hat{\mathbf{z}}\sin\theta \\ \hat{\boldsymbol{\phi}} &= -\hat{\mathbf{x}}\sin\phi + \hat{\mathbf{y}}\cos\phi.\end{aligned}$$
   - (a) (0.25) Show the following relations: $\partial_r\hat{\mathbf{r}} = 0$, $\partial_\theta\hat{\mathbf{r}} = \hat{\boldsymbol{\theta}}$ and $\partial_\phi\hat{\mathbf{r}} = \hat{\boldsymbol{\phi}}\sin\theta$.
   - (b) (0.25) Show the following relations: $\partial_r\hat{\boldsymbol{\theta}} = 0$, $\partial_\theta\hat{\boldsymbol{\theta}} = -\hat{\mathbf{r}}$ and $\partial_\phi\hat{\boldsymbol{\theta}} = \hat{\boldsymbol{\phi}}\cos\theta$.
   - (c) (0.5) Derive similar expressions for $\partial_r\hat{\boldsymbol{\phi}}$, $\partial_\theta\hat{\boldsymbol{\phi}}$ and $\partial_\phi\hat{\boldsymbol{\phi}}$.
   - (d) (1.5) Use the relation for the gradient operator
   $$\boldsymbol{\nabla} \to \left(\hat{\mathbf{r}}\partial_r + \hat{\boldsymbol{\theta}}\frac{1}{r}\partial_\theta + \hat{\boldsymbol{\phi}}\frac{1}{r\sin\theta}\partial_\phi\right)$$
   to derive the following relations
   $$\begin{array}{lll}\hat{\mathbf{r}}\cdot\boldsymbol{\nabla} = \partial_r\,; & \hat{\boldsymbol{\theta}}\cdot\boldsymbol{\nabla} = \frac{1}{r}\partial_\theta\;; & \hat{\boldsymbol{\phi}}\cdot\boldsymbol{\nabla} = \frac{1}{r\sin\theta}\partial_\phi \\ \boldsymbol{\nabla}\cdot\hat{\mathbf{r}} = \frac{2}{r}\;; & \boldsymbol{\nabla}\cdot\hat{\boldsymbol{\theta}} = \frac{\cot\theta}{r}\;; & \boldsymbol{\nabla}\cdot\hat{\boldsymbol{\phi}} = 0\end{array}$$
   - (e) (2.0) Prove the following expression for the divergence of a vector field in spherical coordinates.
   $$\boldsymbol{\nabla}\cdot\mathbf{F} = \left(\partial_r + \frac{2}{r}\right)F_r + \frac{1}{r}\left(\partial_\theta + \cot\theta\right)F_\theta + \frac{1}{r\sin\theta}\partial_\phi F_\phi,$$
   where $\mathbf{F} = \hat{\mathbf{r}}F_r + \hat{\boldsymbol{\theta}}F_\theta + \hat{\boldsymbol{\phi}}F_\phi$.
   - (f) (3.0) Prove for arbitrary orthogonal curvilinear coordinates $\{u, v, w\}$ the relation
   $$\boldsymbol{\nabla}\cdot\hat{\mathbf{r}} = \frac{3}{r} + (\hat{\mathbf{u}}\cdot\mathbf{r})\,h_u^{-1}\partial_u\left(\frac{1}{r}\right) + (\hat{\mathbf{v}}\cdot\mathbf{r})\,h_v^{-1}\partial_v\left(\frac{1}{r}\right) + (\hat{\mathbf{w}}\cdot\mathbf{r})\,h_w^{-1}\partial_w\left(\frac{1}{r}\right). \qquad \text{(a)}$$
   - (g) (0.5) Use the general formula (a) to obtain the relation $\boldsymbol{\nabla}\cdot\hat{\mathbf{r}} = 2/r$.

Q.2 Problem set 1 - solutions

SOLUTIONS PROBLEMS CHAPTER 1

1. (0.5) We first expand the commutator using the Einstein summation convention

$$\begin{aligned}\left[r_i, \mathbf{p}^2\right] &= [r_i, p_j p_j] \\ &= [r_i, p_j]\, p_j + p_j\, [r_i, p_j]\,.\end{aligned}$$

Then using $[r_i, p_j] = i\hbar\delta_{ij}$ with $i, j \in \{x, y, z\}$ we obtain after summation over the repeating index j

$$\begin{aligned}\left[r_i, \mathbf{p}^2\right] &= [r_i, p_j]\, p_j + p_j\, [r_i, p_j] \\ &= i\hbar\delta_{ij} p_j + p_j i\hbar\delta_{ij} \\ &= 2i\hbar p_i. \qquad \square\end{aligned}$$

2. (0.5) We have to prove $\left[L_x, \mathbf{L}^2\right] = 0$. Recall that $\left[L_z, \mathbf{L}^2\right] = 0$ is one of the basic commutation relations of angular momentum operators. Further we know the answer should be independent of the choice of quantization axis. Thus, by choosing the quantization axis along the positive x direction we have $L_x \to L_z$, which implies $\left[L_x, \mathbf{L}^2\right] = 0$. ☐

However, the explicit question was to *use commutator algebra.* Thus we decompose $\mathbf{L}^2$,

$$\left[L_x, \mathbf{L}^2\right] = \left[L_x, L_x^2\right] + \left[L_x, L_y^2\right] + \left[L_x, L_z^2\right].$$

We next evaluate the three terms separately using $[L_x, L_y] = i\hbar L_z$, $[L_y, L_z] = i\hbar L_x$ and $[L_z, L_x] = i\hbar L_y$

$$\begin{aligned}\left[L_x, L_x^2\right] &= [L_x, L_x]\, L_x + L_x\, [L_x, L_x] = 0 \\ \left[L_x, L_y^2\right] &= [L_x, L_y]\, L_y + L_y\, [L_x, L_y] = i\hbar L_z L_y + i\hbar L_y L_z \\ \left[L_x, L_z^2\right] &= [L_x, L_z]\, L_z + L_z\, [L_x, L_z] = -i\hbar L_z L_y - i\hbar L_y L_z.\end{aligned}$$

Adding these terms we find

$$\left[L_x, \mathbf{L}^2\right] = \left[L_x, L_x^2\right] + \left[L_x, L_y^2\right] + \left[L_x, L_z^2\right] = 0. \qquad \square$$

Alternative proof: In Einstein notation we have $[L_i, L_j] = \varepsilon_{ijk} i\hbar L_k$

$$\begin{aligned}\left[L_i, \mathbf{L}^2\right] &= [L_i, L_j^2] \\ &= L_j[L_i, L_j] + [L_i, L_j]L_j \\ &= \varepsilon_{ijk} L_j L_k + \varepsilon_{ijk} L_k L_j \\ &= \varepsilon_{ijk} L_j L_k + \varepsilon_{ikj} L_j L_k \\ &= \varepsilon_{ijk} L_j L_k - \varepsilon_{ijk} L_j L_k = 0.\end{aligned}$$

3. (1.5) We have to proof two equalities

   (a) First we proof the equality at the left

$$\begin{aligned}\left(\frac{\partial}{\partial r} + \frac{1}{r}\right)^2 \psi &= \left(\frac{\partial}{\partial r} + \frac{1}{r}\right)\left(\frac{\partial \psi}{\partial r} + \frac{\psi}{r}\right) \\ &= \left(\frac{\partial^2 \psi}{\partial r^2} + \frac{\partial}{\partial r}\frac{\psi}{r} + \frac{1}{r}\frac{\partial \psi}{\partial r} + \frac{\psi}{r^2}\right) \\ &= \left(\frac{\partial^2 \psi}{\partial r^2} + \frac{1}{r}\frac{\partial \psi}{\partial r} - \frac{\psi}{r^2} + \frac{1}{r}\frac{\partial \psi}{\partial r} + \frac{\psi}{r^2}\right) \\ &= \left(\frac{\partial^2}{\partial r^2} + \frac{2}{r}\frac{\partial}{\partial r}\right)\psi. \qquad \square\end{aligned}$$

(b) The equality at the right is most simply proven starting from the right

$$\begin{aligned}\frac{1}{r}\frac{\partial^2}{\partial r^2}(r\psi) &= \frac{1}{r}\frac{\partial}{\partial r}\left(\psi + r\frac{\partial\psi}{\partial r}\right)\\ &= \frac{1}{r}\left(\frac{\partial\psi}{\partial r} + r\frac{\partial^2\psi}{\partial r^2} + \frac{\partial\psi}{\partial r}\right)\\ &= \left(\frac{\partial^2}{\partial r^2} + \frac{2}{r}\frac{\partial}{\partial r}\right)\psi. \qquad \Box\end{aligned}$$

4. (1.0) The radial momentum operator $p_r = \frac{1}{2}(\hat{\mathbf{r}}\cdot\mathbf{p} + \mathbf{p}\cdot\hat{\mathbf{r}})$ is first turned into quantum mechanical form by applying the correspondence rules $\mathbf{p} \to -i\hbar\boldsymbol{\nabla}$ and $\mathbf{r} \to \mathbf{r}$,

$$p_r\psi = -\frac{i\hbar}{2}\left[\hat{\mathbf{r}}\cdot\boldsymbol{\nabla} + \boldsymbol{\nabla}\cdot\hat{\mathbf{r}}\right]\psi = -\frac{i\hbar}{2}\left[2\hat{\mathbf{r}}\cdot\boldsymbol{\nabla}\psi + \psi\boldsymbol{\nabla}\cdot\hat{\mathbf{r}}\right]. \tag{a}$$

The first term in the brackets is swiftly evaluated in spherical coordinates using Eq. (1.14)

$$\hat{\mathbf{r}}\cdot\boldsymbol{\nabla}\psi = \hat{\mathbf{r}}\cdot\left(\hat{\mathbf{r}}\frac{\partial\psi}{\partial r} + \hat{\boldsymbol{\theta}}\frac{1}{r}\frac{\partial\psi}{\partial\theta} + \hat{\boldsymbol{\phi}}\frac{1}{r\sin\theta}\frac{\partial\psi}{\partial\phi}\right) = \frac{\partial\psi}{\partial r}. \tag{b}$$

The second term yields is simplest done in cartesian coordinates

$$\begin{aligned}\boldsymbol{\nabla}\cdot\left(\frac{\mathbf{r}}{r}\right) &= \frac{\partial}{\partial x}\left(\frac{x}{\sqrt{x^2+y^2+z^2}}\right) + \frac{\partial}{\partial y}\left(\frac{y}{\sqrt{x^2+y^2+z^2}}\right) + \frac{\partial}{\partial z}\left(\frac{z}{\sqrt{x^2+y^2+z^2}}\right)\\ &= \frac{3}{r} - \frac{x^2+y^2+z^2}{r^3} = \frac{2}{r}.\end{aligned} \tag{c}$$

Substituting Eqs. (b) en (c) into (a) we obtain

$$p_r\psi = -i\hbar\left(\frac{\partial}{\partial r} + \frac{1}{r}\right)\psi. \qquad \Box$$

Alternative: $\boldsymbol{\nabla}\cdot\hat{\mathbf{r}}$ can also be derived in *spherical coordinates* - see Problem 5d. For the hardliners the derivation is also given for *arbitrary orthogonal curvilinear coordinates* in Problem 5f,5g

5. (4.5) Consider (right-handed) spherical coordinates

$$\begin{aligned}\hat{\mathbf{r}} &= \hat{\mathbf{x}}\sin\theta\cos\phi + \hat{\mathbf{y}}\sin\theta\sin\phi + \hat{\mathbf{z}}\cos\theta\\ \hat{\boldsymbol{\theta}} &= \hat{\mathbf{x}}\cos\theta\cos\phi + \hat{\mathbf{y}}\cos\theta\sin\phi - \hat{\mathbf{z}}\sin\theta\\ \hat{\boldsymbol{\phi}} &= -\hat{\mathbf{x}}\sin\phi + \hat{\mathbf{y}}\cos\phi.\end{aligned}$$

(a) (0.25) $\partial_r\hat{\mathbf{r}} = 0$ because $\hat{\mathbf{r}}$ does not depend on r,

$$\begin{aligned}\partial_\theta\hat{\mathbf{r}} &= \hat{\mathbf{x}}\cos\theta\cos\phi + \hat{\mathbf{y}}\cos\theta\sin\phi - \hat{\mathbf{z}}\sin\theta = \hat{\boldsymbol{\theta}}\\ \partial_\phi\hat{\mathbf{r}} &= -\hat{\mathbf{x}}\sin\theta\sin\phi + \hat{\mathbf{y}}\sin\theta\cos\phi = \hat{\boldsymbol{\phi}}\,\sin\theta.\end{aligned}$$

(b) (0.25) $\partial_r\hat{\boldsymbol{\theta}} = 0$ because $\hat{\boldsymbol{\theta}}$ does not depend on r,

$$\begin{aligned}\partial_\theta\hat{\boldsymbol{\theta}} &= -\hat{\mathbf{x}}\sin\theta\cos\phi - \hat{\mathbf{y}}\sin\theta\sin\phi - \hat{\mathbf{z}}\cos\theta = -\hat{\mathbf{r}}\\ \partial_\phi\hat{\boldsymbol{\theta}} &= -\hat{\mathbf{x}}\cos\theta\sin\phi + \hat{\mathbf{y}}\cos\theta\cos\phi = \hat{\boldsymbol{\phi}}\,\cos\theta.\end{aligned}$$

(c) (0.5) $\partial_r \hat{\boldsymbol{\phi}} = 0$ because $\hat{\boldsymbol{\phi}}$ does not depend on r,

$$\begin{aligned}
&\partial_\theta \hat{\boldsymbol{\phi}} = 0 \\
&\partial_\phi \hat{\boldsymbol{\phi}} = -\hat{\mathbf{x}} \cos\phi - \hat{\mathbf{y}} \sin\phi = -\hat{\mathbf{r}} \sin\theta - \hat{\boldsymbol{\theta}} \cos\theta.
\end{aligned}$$

(d) (1.5) With the gradient operator

$$\boldsymbol{\nabla} \to \left(\hat{\mathbf{r}} \partial_r + \hat{\boldsymbol{\theta}} \frac{1}{r} \partial_\theta + \hat{\boldsymbol{\phi}} \frac{1}{r \sin\theta} \partial_\phi \right)$$

we derive the following relations

$$\begin{aligned}
\hat{\mathbf{r}} \cdot \boldsymbol{\nabla} &= \hat{\mathbf{r}} \cdot \hat{\mathbf{r}}\, \partial_r + \hat{\mathbf{r}} \cdot \hat{\boldsymbol{\theta}} \frac{1}{r} \partial_\theta + \hat{\mathbf{r}} \cdot \hat{\boldsymbol{\phi}} \frac{1}{r \sin\theta} \partial_\phi = \partial_r \\
\hat{\boldsymbol{\theta}} \cdot \boldsymbol{\nabla} &= \hat{\boldsymbol{\theta}} \cdot \hat{\mathbf{r}}\, \partial_r + \hat{\boldsymbol{\theta}} \cdot \hat{\boldsymbol{\theta}} \frac{1}{r} \partial_\theta + \hat{\boldsymbol{\theta}} \cdot \hat{\boldsymbol{\phi}} \frac{1}{r \sin\theta} \partial_\phi = \frac{1}{r} \partial_\theta \\
\hat{\boldsymbol{\phi}} \cdot \boldsymbol{\nabla} &= \hat{\boldsymbol{\phi}} \cdot \hat{\mathbf{r}}\, \partial_r + \hat{\boldsymbol{\phi}} \cdot \hat{\boldsymbol{\theta}} \frac{1}{r} \partial_\theta + \hat{\boldsymbol{\phi}} \cdot \hat{\boldsymbol{\phi}} \frac{1}{r \sin\theta} \partial_\phi = \frac{1}{r \sin\theta} \partial_\phi
\end{aligned}$$

and for the divergences

$$\begin{aligned}
\boldsymbol{\nabla} \cdot \hat{\mathbf{r}} &= \hat{\mathbf{r}} \cdot \partial_r \hat{\mathbf{r}} + \hat{\boldsymbol{\theta}} \cdot \frac{1}{r} \partial_\theta \hat{\mathbf{r}} + \hat{\boldsymbol{\phi}} \cdot \frac{1}{r \sin\theta} \partial_\phi \hat{\mathbf{r}} = 0 + \hat{\boldsymbol{\theta}} \cdot \hat{\boldsymbol{\theta}} \frac{1}{r} + \hat{\boldsymbol{\phi}} \cdot \hat{\boldsymbol{\phi}} \frac{1}{r} = \frac{2}{r} \\
\boldsymbol{\nabla} \cdot \hat{\boldsymbol{\theta}} &= \hat{\mathbf{r}} \cdot \partial_r \hat{\boldsymbol{\theta}} + \hat{\boldsymbol{\theta}} \cdot \frac{1}{r} \partial_\theta \hat{\boldsymbol{\theta}} + \hat{\boldsymbol{\phi}} \cdot \frac{1}{r \sin\theta} \partial_\phi \hat{\boldsymbol{\theta}} = 0 - \hat{\boldsymbol{\theta}} \cdot \hat{\mathbf{r}} \frac{1}{r} + \hat{\boldsymbol{\phi}} \cdot \hat{\boldsymbol{\phi}} \frac{\cot\theta}{r} = \frac{\cot\theta}{r} \\
\boldsymbol{\nabla} \cdot \hat{\boldsymbol{\phi}} &= \hat{\mathbf{r}} \cdot \partial_r \hat{\boldsymbol{\phi}} + \hat{\boldsymbol{\theta}} \cdot \frac{1}{r} \partial_\theta \hat{\boldsymbol{\phi}} + \hat{\boldsymbol{\phi}} \cdot \frac{1}{r \sin\theta} \partial_\phi \hat{\boldsymbol{\phi}} = 0 + 0 - \hat{\boldsymbol{\phi}} \cdot \hat{\mathbf{r}} \frac{1}{r} - \hat{\boldsymbol{\phi}} \cdot \hat{\boldsymbol{\theta}} \frac{\cot\theta}{r} = 0.
\end{aligned}$$

(e) (2.0) The expression for div$\mathbf{F}$ can be written as

$$\begin{aligned}
\boldsymbol{\nabla} \cdot \mathbf{F} &= \boldsymbol{\nabla} \cdot \hat{\mathbf{r}} F_r + \boldsymbol{\nabla} \cdot \hat{\boldsymbol{\theta}} F_\theta + \boldsymbol{\nabla} \cdot \hat{\boldsymbol{\phi}} F_\phi \\
&= \left(\hat{\mathbf{r}} \cdot \boldsymbol{\nabla} F_r + \hat{\boldsymbol{\theta}} \cdot \boldsymbol{\nabla} F_\theta + \hat{\boldsymbol{\phi}} \cdot \boldsymbol{\nabla} F_\phi \right) + \left(F_r \boldsymbol{\nabla} \cdot \hat{\mathbf{r}} + F_\theta \boldsymbol{\nabla} \cdot \hat{\boldsymbol{\theta}} + F_\phi \boldsymbol{\nabla} \cdot \hat{\boldsymbol{\phi}} \right).
\end{aligned}$$

Substituting the expressions for $\hat{\mathbf{r}} \cdot \boldsymbol{\nabla}$, $\hat{\boldsymbol{\theta}} \cdot \boldsymbol{\nabla} F_\theta$ and $\hat{\boldsymbol{\phi}} \cdot \boldsymbol{\nabla}$ for the first term on the r.h.s. we obtain

$$\left(\hat{\mathbf{r}} \cdot \boldsymbol{\nabla} F_r + \hat{\boldsymbol{\theta}} \cdot \boldsymbol{\nabla} F_\theta + \hat{\boldsymbol{\phi}} \cdot \boldsymbol{\nabla} F_\phi \right) = \partial_r F_r + \frac{1}{r} \partial_\theta F_\theta + \frac{1}{r \sin\theta} \partial_\phi F_\phi$$

Using the relations for div$\hat{\mathbf{r}}$, div$\hat{\boldsymbol{\theta}}$ and div$\hat{\boldsymbol{\phi}}$ the second term yields

$$\left(F_r \boldsymbol{\nabla} \cdot \hat{\mathbf{r}} + F_\theta \boldsymbol{\nabla} \cdot \hat{\boldsymbol{\theta}} + F_\phi \boldsymbol{\nabla} \cdot \hat{\boldsymbol{\phi}} \right) = \frac{2}{r} F_r + \frac{\cot\theta}{r} F_\theta.$$

and combining the two we find

$$\boldsymbol{\nabla} \cdot \mathbf{F} = \partial_r F_r + \frac{1}{r} \partial_\theta F_\theta + \frac{1}{r \sin\theta} \partial_\phi F_\phi + \frac{2}{r} F_r + \frac{\cot\theta}{r} F_\theta. \qquad \square$$

(f) (3.0) For arbitrary orthogonal curvilinear coordinates $\{u, v, w\}$ we have

$$\begin{aligned}
\boldsymbol{\nabla} \cdot \hat{\mathbf{r}} &= \left(\hat{\mathbf{u}} h_u^{-1} \partial_u + \hat{\mathbf{v}} h_v^{-1} \partial_v + \hat{\mathbf{w}} h_w^{-1} \partial_w \right) \cdot \left(\frac{\mathbf{r}}{r} \right) \\
&= \frac{1}{r} \left(\hat{\mathbf{u}} \cdot h_u^{-1} \partial_u \mathbf{r} + \hat{\mathbf{v}} \cdot h_v^{-1} \partial_v \mathbf{r} + \hat{\mathbf{w}} \cdot h_w^{-1} \partial_w \mathbf{r} \right) + \\
&\quad + \left(\hat{\mathbf{u}} \cdot \mathbf{r} \right) h_u^{-1} \partial_u \left(\frac{1}{r} \right) + \left(\hat{\mathbf{v}} \cdot \mathbf{r} \right) h_v^{-1} \partial_v \left(\frac{1}{r} \right) + \left(\hat{\mathbf{w}} \cdot \mathbf{r} \right) h_w^{-1} \partial_w \left(\frac{1}{r} \right).
\end{aligned}$$

This expression may be simplified by using the definition $\hat{\mathbf{a}} = h_a^{-1}\partial_a \mathbf{r}$ with $a \in \{u, v, w\}$,

$$\boldsymbol{\nabla} \cdot \hat{\mathbf{r}} = \frac{3}{r} + (\hat{\mathbf{u}} \cdot \mathbf{r})\, h_u^{-1}\partial_u \left(\frac{1}{r}\right) + (\hat{\mathbf{v}} \cdot \mathbf{r})\, h_v^{-1}\partial_v \left(\frac{1}{r}\right) + (\hat{\mathbf{w}} \cdot \mathbf{r})\, h_w^{-1}\partial_w \left(\frac{1}{r}\right). \tag{d}$$

(g) (0.5) Specializing to spherical coordinates ($\hat{\mathbf{u}} = \hat{\mathbf{r}}$, $\hat{\mathbf{v}} = \hat{\boldsymbol{\theta}}$ and $\hat{\mathbf{w}} = \hat{\boldsymbol{\phi}}$) only the first inner product on the r.h.s. of (d) is nonzero and we have using $h_r = |\partial_r \mathbf{r}| = 1$ we regain the result of Eq. (c)

$$\boldsymbol{\nabla} \cdot \hat{\mathbf{r}} = \frac{3}{r} - \frac{1}{r} = \frac{2}{r}. \qquad \square$$

Q.3 Problem set 2

PROBLEMS CHAPTER 2

1. **Positronium** (a) Consider the Hartree atomic unit of length for H and positronium, which one is larger and by what factor (approximately)? (b) Consider the Hartree atomic unit of energy for H and positronium, which one is larger and by what factor (approximately)?

2. **The size of atoms** (a) What is the largest (ground state) atom in the periodic table? (b) What is the smallest atom in the periodic table, (c) which appendix to the syllabus did you use to find this out?

3. (1.5) **Energy contributions in hydrogenic atoms**: Consider the wavefunction $\psi_{nlm}(\mathbf{r}) = \langle \mathbf{r}|nlm\rangle$ for a hydrogenic atom with nuclear charge $Z\,e$. The total energy of the state ψ_{nlm} can be written as the sum of the contributions of a number of operators, all defined in the Syllabus. In this problem we verify that these contributions add up to the well-known expression for the energy of hydrogen-like levels.

   (a) Give an expression for the expectation value of the radial kinetic energy of this atom in *Hartree* atomic units. Note that the radial kinetic energy is *not* a constant of the motion.

   (b) Idem for the rotational energy (centrifugal contribution).

   (c) Idem for the electrostatic energy.

   (d) Idem for the total kinetic energy.

   (e) Idem for the total potential energy.

   (f) Idem for the total energy. Note that this is a constant of the motion.

   Important: Do not rederive the expressions, certainly not Problem 2.3! Simply use the expressions for the radial averages given in the lecture notes. The idea behind this problem is to realize which terms from the Hamiltonian give an l-dependent contribution and which are l independent.

4. (1.5) **Radial wavefunctions as (anharmonic) oscillator states:** The principal quantum number of the electronic state $|n, l, m_l\rangle$ is related to the number of nodes (n') of the corresponding wavefunction. Such a correspondence exists for any oscillator.

   (a) How many *nodes* do you count for the radial wavefunctions $R_{1s}(r), R_{2s}(r), \cdots R_{ns}(r)$ outside the origin?

   (b) Idem for $R_{2p}(r), R_{3p}(r), \cdots R_{np}(r)$ outside the origin;

   (c) Idem for $R_{3d}(r), R_{4d}(r), \cdots R_{nd}(r)$ outside the origin;

   (d) Propose an expression for the relation between n and n';

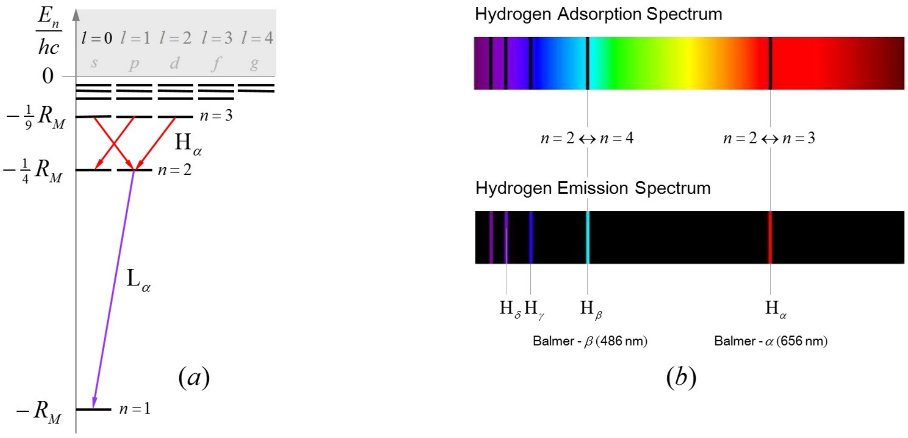
   (e) Can n' be identified with the "radial quantum number" of the radial wave equation?

5. (2.0) **Plotting rotational wavefunctions:** In a polar diagram we plot the *modulus* of a function $f(\theta)$ as the distance to the origin for each value of θ in the interval $0 \leq \theta \leq 2\pi$. Plot $Y_l^m(\theta, \phi)$ (as defined in Appendix L.9.1) for $l = 1$; $m_l = -1, 0, 1$ as a polar plot versus θ in the xz plane ($\phi = 0$). Indicate the regions of positive or negative sign of the spherical harmonic. The use of Mathematica or similar programs is not permitted.

   (a) Idem for $l = 2$; $m_l = -2, -1, 0, 1, 2$.

   (b) Idem for $l = 0$; $m_l = 0$)

6. (3.0) **And then there was light - optical dipole transitions:** Have a look at the Balmer spectrum of atomic hydrogen.



(a) (b)

The sketch of the level structure shows that three different transitions contribute to the Balmer spectrum. Without explanation we point out that for "ordinary" optical transitions, like those of the Balmer spectrum, are induced by the electric-dipole coupling to the electromagnetic field (cf. § 2.5).

(a) (0.25) Give the expression for the *dipole operator*

(b) (0.25) Give the expression for the *transition dipole moment* of the transition $|nlm\rangle \leftrightarrow |n'l'm'\rangle$

(c) (0.5) Give the expression for the $nlm \leftrightarrow n'l'm'$ *transition strength* $D^2_{nlm,n'l'}$. This quantity is tabulated for many atomic transitions; by now we can calculate these for hydrogen.

(d) (1.0) The transition $2p \to 1s$ is known as the Lyman-α line ($\lambda = 121.6$ nm) and the transition $3p \to 1s$ as the Lyman-β line ($\lambda = 102.6$ nm). The spontaneous lifetime τ for the transition $|n'l'm'\rangle \to |nlm\rangle$ from the excited state $|n'l'm'\rangle$ is given by the relation (not derived within this course)

$$\frac{1}{\tau} = \frac{8\pi^2}{3\hbar\varepsilon_0}\frac{D^2_{n'l'm',nlm}}{\lambda^3}, \tag{a}$$

where λ is the wavelength of the emitted light. Calculate the lifetimes of the $3p$ and the $2p$ levels in hydrogen (NB. *the contribution of the* $3p \to 2s$ *transition to the lifetime of the* $3p$ *level may be neglected*).

(e) (1.0) The lifetime of the $3d$ level in atomic hydrogen is 15.6 ns, that of the $3s$ level 160 ns. Explain the origin of this difference. Verify that the lifetimes of the $3d$ levels with $|lm\rangle = |22\rangle$ and $|lm\rangle = |21\rangle$ are equal. *Hint:* use Eq.(a) and sum the partial contributions of the various transitions from the initial state,

$$\frac{1}{\tau} = \frac{1}{\tau_a} + \frac{1}{\tau_b} + \cdots .$$

The feature that we can simply add the decay rates of the magnetic sublevels (without worrying about the occupation of these sublevels in a gas sample) is a famous result known as the f *sum rule*, (a summation over so-called oscillator strengths).

Q.4 Problem set 2 - solutions

SOLUTIONS PROBLEMS CHAPTER 2

1. **Positronium:** The reduced mass of a hydrogenic atom is given by

$$m_r = \frac{m_e M}{m_e + M},$$

where m_e is the electron mass and M the nuclear mass. The Bohr radius a.u. and Hartree a.u. are given by

$$a = (1 + m_e/M)a_0 \quad \text{and} \quad R_M = R_\infty/(1 + m_e/M),$$

where R_∞ and a_0 are tabulated to high precision - see Table

$$R_\infty = \alpha^2 m_e c/2h = 1.097\,373\,156\,8160(21) \times 10^7 \mathrm{m}^{-1}$$
$$a_0 = \alpha/4\pi R_\infty \simeq 5.2 \times 10^{-11} \text{ m}$$

We compare *hydrogen* (H) to *positronium* (Ps):

   (a) For H we have $M \gg m_e$ and calculate $m_r \simeq m_e$; hence, $a \simeq a_0$ and $R_M \simeq R_\infty$

   (b) For Ps we have $M = m_e$ and calculate $m_r = m_e/2$; hence, $a \simeq 2a_0$ and $R_M \simeq R_\infty/2$

   (c) Therefore, $a(\mathrm{H})/a(\mathrm{Ps}) \approx 1/2$ and $E_H(\mathrm{H})/E_H(\mathrm{Ps}) \approx 2$.

2. **The size of atoms.** Cs is the largest and He the smallest since they have the smallest/largest binding energy (Appendix C).

3. (1.5) **Energy contributions in hydrogenic atoms**: Consider the wavefunction $\psi_{nlm}(\mathbf{r}) = \langle \mathbf{r}|nlm\rangle$ for a hydrogenic atom with nuclear charge $Z\,e$.

   (a) The expectation value for the radial kinetic energy of this atom in *Hartree* atomic units is

$$\langle -\frac{1}{2\rho}\frac{\partial^2}{\partial\rho^2}\rho\rangle = \frac{Z^2}{2n^2}\left[1 - \frac{2l\,(l+1)}{n\,(2l+1)}\right] \qquad \text{(Hartree)}$$

   (b) The rotational energy (centrifugal contribution) is

$$\langle \frac{l\,(l+1)}{2\rho^2}\rangle = \frac{Z^2}{2n^2}\frac{2l\,(l+1)}{n\,(2l+1)} \qquad \text{(Hartree)}$$

   (c) The electrostatic energy is

$$\langle -\frac{Z}{\rho}\rangle = -2\frac{Z^2}{2n^2} \qquad \text{(Hartree)}$$

   (d) The total kinetic energy is

$$\langle -\frac{1}{2\rho}\frac{\partial^2}{\partial\rho^2}\rho + \frac{l\,(l+1)}{2\rho^2}\rangle = \frac{Z^2}{2n^2} \qquad \text{(Hartree)}$$

   (e) The total potential energy is

$$\langle -\frac{Z}{\rho}\rangle = -2\frac{Z^2}{2n^2} \qquad \text{(Hartree)}$$

(f) The total energy is

$$\langle -\frac{1}{2\rho}\frac{\partial^2}{\partial\rho^2}\rho + \frac{l\,(l+1)}{2\rho^2} - \frac{Z}{\rho}\rangle = -\frac{1}{2}\frac{Z^2}{n^2} \qquad \text{(Hartree)}$$

Note that the contributions, indeed, add up to the well-known expression for the total energy, which is independent of l.

4. (1.5) **Radial wavefunctions as (anharmonic) oscillator states:** The principal quantum number of the electronic state $|n, l, m_l\rangle$ is related to the number of nodes, n',of the corresponding wavefunction (outside the origin).

(a) The radial wavefunctions $R_{1s}(r), R_{2s}(r), \cdots R_{ns}(r)$ have $0, 1, \cdots, n-1$ nodes, respectively;

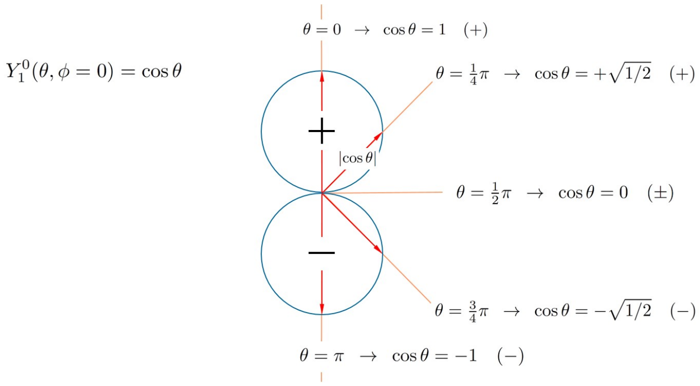
(b) The radial wavefunctions $R_{2p}(r), R_{3p}(r), \cdots R_{np}(r)$ have $0, 1 \cdots, n-2$ nodes (outside the origin), respectively;

(c) The radial wavefunctions $R_{3d}(r), R_{4d}(r), \cdots R_{nd}(r)$ have $0, 1 \cdots, n-3$ nodes (outside the origin), respectively;

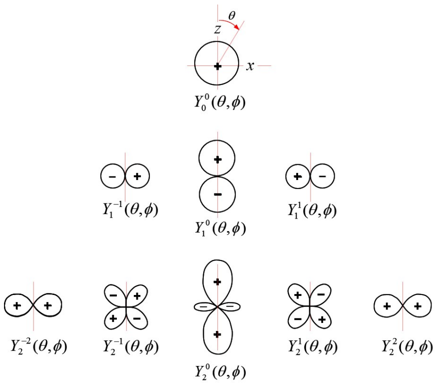
(d) The requested expression is $n = n' + l + 1$;

(e) Yes, n' is the "radial quantum number" of the radial wave equation.

5. (2.0) **Plotting rotational wavefunctions:** In a *polar plot* we plot the modulus of a *function of direction* versus *direction (in real space).* In the polar plot of $Y_l^m(\theta,\phi)$ (for the azimuthal angle $\phi = 0$), we plot $|Y_l^m(\theta,\phi)|$ versus θ. The angle $\phi = 0$ is chosen because in this plane the $Y_l^m(\theta,\phi)$ are *real* functions of direction. For $Y_1^0(\theta,\phi)$ this is illustrated below



The polar diagrams of the requested spherical harmonics are sketched below for $l = 0, 1, 2$:



6. (3.0) **And then there was light - optical dipole transitions:** Answer to the questions:

   (a) (0.25) the *electric-dipole operator* is

$$\mathbf{d} = -\,e\mathbf{r} = -\,ea\rho\hat{\mathbf{r}}.$$

   (b) (0.25) the transition dipole for the transition $|nlm\rangle \leftrightarrow |n'l'm'\rangle$ is given by

$$\mathbf{D}_{eg} = -ea\,\langle n'l'm'|\,\rho\hat{\mathbf{r}}\,|nlm\rangle = -ea\,\langle n'l'||\rho||nl\rangle\,\langle l'm'|\,\hat{\mathbf{r}}\,|lm\rangle\,.$$

   (c) (0.5) The $n'l'm' \leftrightarrow nlm$ atomic *electric-dipole transition strength* is given by

$$D^2_{n'l'm',nlm} = e^2a^2\mathcal{R}^2_{n'l',nl}\mathcal{A}^2_{l'm',lm}.$$

   (d) (1.0) The *electric-dipole transition rate* is given by (without derivation)

$$\frac{1}{\tau} = \frac{8\pi^2}{3\hbar\varepsilon_0}\frac{D^2_{n'l'm',nlm}}{\lambda^3}.$$

   First we calculate the Lyman-α ($n = 2$) decay rate in hydrogen ($Z = 1$). Using Eqs. (2.85) and (2.85) we find for the radial integrals

$$\mathcal{R}^2_{2p,1s} = \left(\frac{1}{Z}2^4n^{7/2}\frac{(n-1)^{n-5/2}}{(n+1)^{n+5/2}}\right)^2 \Rightarrow \mathcal{R}^2_{2p,1s} = \frac{2^{15}}{3^9} = 1.66479$$

$$\mathcal{R}^2_{3p,1s} = \left(\frac{1}{Z}2^4n^{7/2}\frac{(n-1)^{n-5/2}}{(n+1)^{n+5/2}}\right)^2 \Rightarrow \mathcal{R}^2_{3p,1s} = \frac{3^7}{2^{13}} = 0.266968$$

$$\left(\frac{\mathcal{R}_{3p,1s}}{\mathcal{R}_{2p,1s}}\right)^2 = \frac{3^{16}}{2^{28}} = 0.160362$$

   The Lyman-α/Lyman-β wavelength ratio is

$$\left(\frac{\lambda_{2p,1s}}{\lambda_{3p,1s}}\right)^3 = \left(\frac{121.6}{102.6}\right)^3 = 1.66479.$$

For the angular integral we find for both Lyman-α and Lyman-β with the aid of Eqs. (2.86) and (J.16)

$$\mathcal{A}^2_{1m',00} = \begin{pmatrix} 1 & 1 & 0 \\ -m' & m' & 0 \end{pmatrix}^2 = \frac{1}{3}.$$

Thus we obtain for Lyman-α the oscillator strength in atomic units:

$$D^2_{2p,1s} = \mathcal{R}^2_{2p,1s}\mathcal{A}^2_{1m',00} = 0.55492.$$

With these numbers we calculate for the Lyman-α wavelength $\lambda_{2p,1s} = 121.6\,\text{nm}$ the lifetime $\tau_{2p,1s} = 1.6\,\text{ns}$.
Next we calculate the ratio of the Lyman-β and Lyman-α transition rates

$$\begin{aligned}\frac{\tau_{2p,1s}}{\tau_{3p,1s}} &= \frac{D^2_{3p,1s}}{D^2_{2p,1s}}\left(\frac{\lambda_{2p,1s}}{\lambda_{3p,1s}}\right)^3 \\ &= \left(\frac{\mathcal{R}_{3p,1s}}{\mathcal{R}_{2p,1s}}\right)^2\left(\frac{\mathcal{A}_{1m,00}}{\mathcal{A}_{1m',00}}\right)^2\left(\frac{\lambda_{2p,1s}}{\lambda_{3p,1s}}\right)^3 \\ &= \left(\frac{\mathcal{R}_{3p,1s}}{\mathcal{R}_{2p,1s}}\right)^2\left(\frac{\lambda_{2p,1s}}{\lambda_{3p,1s}}\right)^3 = 0.160362 * 1.66479 = \frac{1}{3.7457}.\end{aligned}$$

Hence, the Lyman-β decay is 3.7457 times slower than the Lyman-α decay, $\tau_{3p,1s} = 6\,\text{ns}$.

(e) (1.0) The lifetime of the $3d$ level of hydrogen is 15.6 ns and that of the $3s$ level 160 ns. To understand the difference we compare the expressions for the decay rates

$$\frac{1}{\tau_{3d}} = \sum_{m=-1}^{1}\frac{8\pi^2}{3\hbar\varepsilon_0}\frac{D^2_{3dm',2pm}}{\lambda^3} \tag{Q.1}$$

$$\frac{1}{\tau_{3s}} = \sum_{m=-1}^{1}\frac{8\pi^2}{3\hbar\varepsilon_0}\frac{D^2_{3s0,2pm}}{\lambda^3}, \tag{Q.2}$$

Because $\lambda_{3d\to 2p} = \lambda_{3s\to 2p}$ the ratio for the lifetimes can be written as

$$\frac{\tau_{3d}}{\tau_{3s}} = \frac{\sum_{m=-1}^{1} D^2_{3s0,2pm}}{\sum_{m=-1}^{1} D^2_{3dm',2pm}} = \frac{\mathcal{R}^2_{3s,2p}}{\mathcal{R}^2_{3d,2p}}\frac{\sum_{m=-1}^{1}\mathcal{A}^2_{3s0,2pm}}{\sum_{m=-1}^{1}\mathcal{A}^2_{3dm',2pm}}$$

The radial integrals yield

$$\begin{aligned}\mathcal{R}^2_{ns,2p} &= \left(2^7\sqrt{2/3}\,n^{9/2}\frac{(n-2)^{n-3}}{(n+2)^{n+3}}\right)^2 \Rightarrow \mathcal{R}^2_{3s,2p} = 0.880\,6 \\ \mathcal{R}^2_{nd,2p} &= \left(2^9\sqrt{2/3}\,n^5(n^2-1)\frac{(n-2)^{n-3}}{(n+2)^{n+3}}\sqrt{\frac{(n-3)!}{(n+2)!}}\right)^2 \Rightarrow \mathcal{R}^2_{3d,2p} = 22.543\end{aligned}$$

Hence,

$$\frac{\tau_{3d}}{\tau_{3s}} = \frac{0.880\,6}{22.543}\frac{\sum_{m=-1}^{1}\mathcal{A}^2_{3s0,2pm}}{\sum_{m=-1}^{1}\mathcal{A}^2_{3dm',2pm}}.$$

The angular integrals yield:

$$|2,m\rangle \to |1,m'\rangle = \begin{cases} |2,2\rangle \to |1,1\rangle & \mathcal{A}^2_{2,2;1,1} = \frac{2}{5} \\ |2,1\rangle \to |1,0\rangle, |1,1\rangle & \mathcal{A}^2_{2,1;1,0} = \frac{1}{5}, \frac{1}{5} \\ |2,0\rangle \to |1,1\rangle, |1,0\rangle, |1,-1\rangle & \mathcal{A}^2_{2,0;1,1} = \frac{1}{15}, \frac{4}{15}, \frac{1}{15} \\ |2,-1\rangle \to |1,0\rangle, |1,-1\rangle & \mathcal{A}^2_{2,-1;1,0} = \frac{1}{5}, \frac{1}{5} \\ |2,-2\rangle \to |1,-1\rangle & \mathcal{A}^2_{2,-2;1,-1} = \frac{2}{5} \end{cases}$$

$$|0,0\rangle \to |1,m'\rangle = \Big\{ |0,0\rangle \to |1,1\rangle, |1,0\rangle, |1,-1\rangle \; \mathcal{A}^2_{2,0;1,1} = \tfrac{1}{3}, \tfrac{1}{3}, \tfrac{1}{3}$$

Hence, we find for the ration of lifetimes

$$\frac{\tau_{3d}}{\tau_{3s}} = \frac{0.880\,6}{22.543}\frac{1}{2/5} = 0.09765\,8 \simeq \frac{15.6}{160}.$$

The decay of the $3d$ level is faster because the transition dipole is much larger, not surprising because the size of the $3d$ orbital is larger than that of the $3s$ orbital. Note that there is no competition with the Lyman transitions $3s \to 1s$ and $3d \to 1s$ because these are forbidden for electric-dipole transitions. On the contrary, the $3s \to 1s$ decay is much faster (0.427 ns) because it is allowed.

Q.5 Problem set 3

PROBLEMS CHAPTER 3

Angular momentum

1. **Spin and Pauli matrices**: In the matrix representation the operators associated with spin angular momentum $\mathbf{S}$ can be expressed in terms of the Pauli matrices, $\mathbf{S} = \frac{1}{2}\hbar\boldsymbol{\sigma}$. These operators act in a *two-dimensional Hilbert space* with basis vectors

$$|\uparrow\rangle \equiv |1/2, 1/2\rangle = \begin{pmatrix} 1 \\ 0 \end{pmatrix}, \quad |\downarrow\rangle \equiv |1/2, -1/2\rangle = \begin{pmatrix} 0 \\ 1 \end{pmatrix}.$$

The Pauli matrices are 2 × 2 matrices

$$\sigma_x = \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}, \quad \sigma_y = \begin{pmatrix} 0 & -i \\ i & 0 \end{pmatrix}, \quad \sigma_z = \begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix}.$$

   (a) Derive matrix expressions for the operators S_z, S_+ and S_-.
   (b) Calculate the eigenvalues of S_z for the eigenstates $|\uparrow\rangle$ and $|\downarrow\rangle$.
   (c) Show that S_+ satisfies the properties of a raising operator.
   (d) Verify the commutation relation $[S_x, S_y] = i\hbar S_z$ by matrix multiplication.
   (e) Demonstrate the Closure relation for the eigenstates.

2. **Inner products of angular momentum operators**: There are three inner-product rules for the inner product $\mathbf{L} \cdot \mathbf{S}$:

   (a) Express $\mathbf{L} \cdot \mathbf{S}$ in the cartesian components of $\mathbf{L}$ and $\mathbf{S}$.
   (b) Express $\mathbf{L} \cdot \mathbf{S}$ in a form containing the shift operators of $\mathbf{L}$ and $\mathbf{S}$.
   (c) Express $\mathbf{L} \cdot \mathbf{S}$ in a form containing the total angular momentum $\mathbf{J} = \mathbf{L} + \mathbf{S}$.
   (d) Show that $\mathbf{L} \cdot \mathbf{S}$ conserves $m_l + m_s$.
   (e) Show that $\mathbf{L} \cdot \mathbf{S}$ conserves the quantum numbers l, s and j.

   Note: that j, m_j are the quantum numbers corresponding to the angular momentum $\mathbf{J}$ like l, m_l and s, m_s are those of the angular momenta $\mathbf{L}$ and $\mathbf{S}$, respectively.

3. **Clebsch-Gordan decompositions for identical particles**: Derive the following symmetry relations for the coupling of two angular momenta, j_1 and j_2, of identical particles ($j_1 = j_2 = j$, where j is integral for bosons and half-integral for fermions) :

$$\tfrac{1}{2}\left[|jm_1; jm_2\rangle \pm |jm_2; jm_1\rangle\right] = \begin{cases} \displaystyle\sum_{J=\text{even/odd}}^{2j} \sum_{M=-J}^{J} |JM\rangle\langle JM|jm_1; jm_2\rangle & \text{(bosons)} \\ \displaystyle\sum_{J=\text{odd/even}}^{2j} \sum_{M=-J}^{J} |JM\rangle\langle JM|jm_1; jm_2\rangle. & \text{(fermions)} \end{cases}$$

   Hint: Use the exchange rule for Clebsch-Gordan coefficients which follows directly from the column-interchange rule of $3j$ symbols (see Problem J.1)

$$\langle jm_2 jm_1|JM\rangle = (-1)^{J-2j}\langle jm_1 jm_2|JM\rangle.$$

4. **Cross product of angular momentum operators**: The commutator of two *vectors* is a second order tensor. This becomes evident in the Einstein notation $[\mathbf{A},\mathbf{B}] \Leftrightarrow [\mathbf{A},\mathbf{B}]_{ij} = [A_i, B_j] = A_iB_j - B_jA_i \Leftrightarrow \mathbf{A}\mathbf{B}^T - (\mathbf{B}\mathbf{A}^T)^T$, where $()^T$ represents matrix transposition.
   (a) Write the cross product $\mathbf{L}\times\mathbf{L}$ as a determinant and show that $\mathbf{L}\times\mathbf{L} = i\hbar\mathbf{L}$.
   (b) Express $(\mathbf{L}\times\mathbf{L})_i$ in the Einstein notation and show that $(\mathbf{L}\times\mathbf{L})_i = i\hbar L_i$.
   (c) Write the tensor $\mathbf{A}\mathbf{B}^T$ as a matrix and show that $[\mathbf{A},\mathbf{B}] = 0$ if and only if all components of $\mathbf{A}$ commute with all components of $\mathbf{B}$.
   (d) Give an expression for $[\mathbf{L},\mathbf{L}]$ in matrix form and show that $[\mathbf{L},\mathbf{L}] \neq 0$.
   (e) Give an expression for $[\mathbf{L},\mathbf{L}]_{ij}$ in the Einstein notation.
   (f) Calculate $\left[\mathbf{L}^2,\mathbf{L}^2\right]$.

5. **Tensor products of state vectors**: Consider two angular momenta, $\boldsymbol{j}_1$ and $\boldsymbol{j}_2$, acting in vector spaces of dimension $d_1 = 2$ and $d_2 = 3$, respectively (i.e., $j_1 = \frac{1}{2}$ and $j_2 = 1$). The corresponding eigenstates are given by

$$|\tfrac{1}{2},+\tfrac{1}{2}\rangle = \begin{pmatrix}1\\0\end{pmatrix}, \qquad |\tfrac{1}{2},-\tfrac{1}{2}\rangle = \begin{pmatrix}0\\1\end{pmatrix} \tag{Q.3}$$

and

$$|1,+1\rangle = \begin{pmatrix}1\\0\\0\end{pmatrix}, \qquad |1,0\rangle = \begin{pmatrix}0\\1\\0\end{pmatrix}, \qquad |1,-1\rangle = \begin{pmatrix}0\\0\\-1\end{pmatrix}. \tag{Q.4}$$

In the *uncoupled* representation the eigenstate $|\frac{1}{2},+\frac{1}{2};1,0\rangle$ is given by the tensor product

$$|\tfrac{1}{2},+\tfrac{1}{2};1,0\rangle = |\tfrac{1}{2},+\tfrac{1}{2}\rangle \otimes |1,0\rangle = \begin{pmatrix}1\\0\end{pmatrix} \otimes \begin{pmatrix}0\\1\\0\end{pmatrix} = \begin{pmatrix}0\\1\\0\\0\\0\\0\end{pmatrix}.$$

Note that for the doublet state $|\frac{1}{2},+\frac{1}{2}\rangle$ the tensor product $|\frac{1}{2},+\frac{1}{2}\rangle \otimes |1,0\rangle$ provides a three-dimensional subspace for the triplet state $|1,0\rangle$. Analogously, for the triplet state $|1,0\rangle$, the tensor product $|1,0\rangle \otimes |\frac{1}{2},+\frac{1}{2}\rangle$ provides a two-dimensional subspace for the doublet state $|\frac{1}{2},+\frac{1}{2}\rangle$. In both ways we obtain a 6-dimensional Hilbert space (for the tensors $\boldsymbol{j}_1 \otimes \boldsymbol{j}_2$ and $\boldsymbol{j}_2 \otimes \boldsymbol{j}_1$, respectively). In the *uncoupled* representation the *stretched state* is given by $|j_1, j_1; j_2, j_2\rangle = |j_1, j_1\rangle \otimes |j_2, j_2\rangle$; i.e., for $j_1 = \frac{1}{2}$ and $j_2 = 1$ this corresponds to $|\frac{1}{2},+\frac{1}{2};1,1\rangle = |\frac{1}{2},+\frac{1}{2}\rangle \otimes |1,1\rangle$. The tensor product is a so-called ordered product.

   (a) Do the states $|\frac{1}{2},+\frac{1}{2}\rangle$ and $|1,0\rangle$ commute under the tensor product?
   (b) Do the states $|\frac{1}{2},+\frac{1}{2}\rangle$ and $|1,1\rangle$ commute under the tensor product?
   (c) Why is the tensor product called an ordered product?

Q.6 Problem set 3 - solutions

SOLUTIONS PROBLEMS CHAPTER 3

Angular momentum

1. In the matrix representation the operators associated with spin angular momentum $\mathbf{S}$ can be expressed in terms of the Pauli matrices, $\mathbf{S} = \frac{1}{2}\hbar\sigma$. These operators act in a *two-dimensional Hilbert space* with basis vectors

$$|\uparrow\rangle \equiv |1/2, 1/2\rangle = \begin{pmatrix} 1 \\ 0 \end{pmatrix}, \quad |\downarrow\rangle \equiv |1/2, -1/2\rangle = \begin{pmatrix} 0 \\ 1 \end{pmatrix}.$$

The Pauli matrices are 2 × 2 matrices

$$\sigma_x = \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}, \quad \sigma_y = \begin{pmatrix} 0 & -i \\ i & 0 \end{pmatrix}, \quad \sigma_z = \begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix}.$$

The answers are:

(a) Matrix expressions for the operators S_z, S_+ and S_- are

$$S_z = \hbar \begin{pmatrix} 1/2 & 0 \\ 0 & -1/2 \end{pmatrix};$$
$$S_+ = (S_x + iS_y) = \hbar \begin{pmatrix} 0 & 1 \\ 0 & 0 \end{pmatrix}; \quad S_- = (S_x - iS_y) = \hbar \begin{pmatrix} 0 & 0 \\ 1 & 0 \end{pmatrix}$$

(b) The eigenvalues of S_z for the eigenstates $|\uparrow\rangle$ and $|\downarrow\rangle$ are

$$\hbar \begin{pmatrix} 1/2 & 0 \\ 0 & -1/2 \end{pmatrix} \begin{pmatrix} 1 \\ 0 \end{pmatrix} = +\frac{1}{2}\hbar \begin{pmatrix} 1 \\ 0 \end{pmatrix}; \quad \hbar \begin{pmatrix} 1/2 & 0 \\ 0 & -1/2 \end{pmatrix} \begin{pmatrix} 0 \\ 1 \end{pmatrix} = -\frac{1}{2}\hbar \begin{pmatrix} 0 \\ 1 \end{pmatrix}$$

(c) Show that S_+ satisfies the properties of a raising operator

$$\hbar \begin{pmatrix} 0 & 1 \\ 0 & 0 \end{pmatrix} \begin{pmatrix} 0 \\ 1 \end{pmatrix} = \hbar \begin{pmatrix} 1 \\ 0 \end{pmatrix}; \quad \hbar \begin{pmatrix} 0 & 1 \\ 0 & 0 \end{pmatrix} \begin{pmatrix} 1 \\ 0 \end{pmatrix} = 0$$

(d) The commutation relation $[S_x, S_y] = i\hbar S_z$ is given by

$$\begin{aligned} [S_x, S_y] &= \frac{\hbar^2}{4} \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix} \begin{pmatrix} 0 & -i \\ i & 0 \end{pmatrix} - \frac{\hbar^2}{4} \begin{pmatrix} 0 & -i \\ i & 0 \end{pmatrix} \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix} \\ &= \frac{\hbar^2}{4} \begin{pmatrix} i & 0 \\ 0 & -i \end{pmatrix} - \frac{\hbar^2}{4} \begin{pmatrix} -i & 0 \\ 0 & i \end{pmatrix} \\ &= \frac{\hbar^2}{2} \begin{pmatrix} i & 0 \\ 0 & -i \end{pmatrix} = i\hbar \frac{\hbar}{2} \begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix} = i\hbar S_z \end{aligned}$$

(e) The Closure relation for the eigenstates is

$$|\uparrow\rangle\langle\uparrow| + |\downarrow\rangle\langle\downarrow| = \begin{pmatrix} 1 \\ 0 \end{pmatrix} (1\,0) + \begin{pmatrix} 0 \\ 1 \end{pmatrix} (0\,1) = \begin{pmatrix} 1 & 0 \\ 0 & 0 \end{pmatrix} + \begin{pmatrix} 0 & 0 \\ 0 & 1 \end{pmatrix} = \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix} = \mathbb{1}.$$

2. **Inner product of angular momentum operators**: The three inner-product rules are:

(a) Rule (a) is simply the definition of the inner product in cartesian coordinates

$$\mathbf{L}\cdot\mathbf{S} = L_xS_x + L_yS_y + L_zS_z.$$

(b) Using the definitions for the shift operators we have

$$\begin{aligned} L_+S_- &= (L_x + iL_y)(S_x - iS_y) = L_xS_x + L_yS_y + i(L_yS_x - L_xS_y) \\ L_-S_+ &= (L_x - iL_y)(S_x + iS_y) = L_xS_x + L_yS_y - i(L_yS_x - L_xS_y)\,. \end{aligned}$$

Adding these expressions and using rule (a) we obtain after rearrangement of terms

$$\mathbf{L}\cdot\mathbf{S} = L_zS_z + \frac{1}{2}\left[L_+S_- + L_-S_+\right]$$

(c) $\mathbf{L}\cdot\mathbf{S} = \frac{1}{2}\left[\mathbf{J}^2 - \mathbf{L}^2 - \mathbf{S}^2\right]$: This rule follows straightforwardly from the inner product

$$\mathbf{J}^2 = (\mathbf{L}+\mathbf{S})^2 = \mathbf{L}^2 + \mathbf{S}^2 + 2\mathbf{L}\cdot\mathbf{S}$$

because **L** and **S** commute (they act in independent sectors of Hilbert space).

(d) To demonstrate this we consider the state $|\psi\rangle$ which is in some state with known values for the quantum numbers $m_l + m_s = M$. Hence, the state $|\psi\rangle$ needs to be an eigenstate of $J_z = L_z + S_z$. An arbitrary state of the angular momentum **J** can be written as a linear combination of all states $|lm_l; sm_s\rangle$ with $m_l + m_s = M$. With rule (b) we find that whenever L_+ raises m_l by 1 the S_- will lower m_s by 1 (and vice versa); hence, $m_l + m_s$ will be conserved.

(e) To demonstrate this we consider the state $|\psi\rangle$ which is in some state with *known values* for the quantum numbers l, s and j; i.e., the state can be written as a linear combination of the following types

$$\begin{aligned} |\psi\rangle &= \sum_{j=|l-s|-j}^{j=l+s}\;\sum_{m_j=-j}^{m_j=j} |ls; jm_j\rangle\langle ls; jm_j|\psi\rangle = \sum_{m_j=-j}^{m_j=j} |ls; jm_j\rangle\langle ls; jm_j|\psi\rangle \quad (j \text{ is known}) \\ |\psi\rangle &= \sum_{m_l=-l}^{m_l=l}\;\sum_{m_s=-s}^{m_s=s} |lm_l; sm_s\rangle\langle lm_l; sm_s|\psi\rangle \end{aligned}$$

With rule c we find that the quantum numbers l, s and j are conserved because j is conserved by $\mathbf{J}^2$ (see upper line) l is conserved by $\mathbf{L}^2$ and s is conserved by $\mathbf{S}^2$(see lower line). Hence the three vectors of the vector addition triangle are conserved.

3. **Clebsch-Gordan decompositions for identical particles**: Derive the following symmetry relations for the coupling of two angular momenta, j_1 and j_2, of identical particles ($j_1 = j_2 = j$, where j is *integral for bosons* and *half-integral for fermions*) :

$$\tfrac{1}{2}\left[|jm_1;jm_2\rangle \pm |jm_2;jm_1\rangle\right] = \begin{cases} \displaystyle\sum_{J=\mathrm{even/odd}}^{2j}\ \sum_{M=-J}^{J} |JM\rangle\langle JM|jm_1;jm_2\rangle & \text{(bosons)} \\ \displaystyle\sum_{J=\mathrm{odd/even}}^{2j}\ \sum_{M=-J}^{J} |JM\rangle\langle JM|jm_1;jm_2\rangle. & \text{(fermions)} \end{cases}$$

Answer:
We start with the Clebsch-Gordan decomposition

$$|jm_1;jm_2\rangle = \sum_{J=0}^{2j}\sum_{M=-J}^{J} |JM\rangle\langle JM|jm_1;jm_2\rangle.$$

From Problem J.1 we use the exchange rule

$$\langle jm_2jm_1|JM\rangle = (-1)^{J-2j}\langle jm_1jm_2|JM\rangle.$$

Note that the exchange symmetry is independent of the value of M. Substituting the exchange rule into the Clebsch-Gordan expansion we find

$$|jm_1;jm_2\rangle + |jm_2;jm_1\rangle = \sum_{J=0}^{2j}\sum_{M=-J}^{J} [1+(-1)^{J-2j}]|JM\rangle\langle JM|jm_1;jm_2\rangle.$$

For bosons $2j$ is even and the Clebsch-Gordan expansion becomes

$$\begin{aligned} |jm_1;jm_2\rangle + |jm_2;jm_1\rangle &= \sum_{J=0}^{2j}\sum_{M=-J}^{J} [1+(-1)^{J}]|JM\rangle\langle JM|jm_1;jm_2\rangle \\ &= 2\sum_{J=\mathrm{even}}^{2j}\sum_{M=-J}^{J} |JM\rangle\langle JM|jm_1;jm_2\rangle. \end{aligned}$$

For fermions $2j$ is odd and the Clebsch-Gordan expansion becomes

$$\begin{aligned} |jm_1;jm_2\rangle + |jm_2;jm_1\rangle &= \sum_{J=0}^{2j}\sum_{M=-J}^{J} [1-(-1)^{J}]|JM\rangle\langle JM|jm_1;jm_2\rangle \\ &= 2\sum_{J=\mathrm{odd}}^{2j}\sum_{M=-J}^{J} |JM\rangle\langle JM|jm_1;jm_2\rangle. \end{aligned}$$

4. **Cross product of angular momentum operators**: The commutator of two *vectors* is a second order tensor. This becomes evident in the Einstein notation $[\mathbf{A},\mathbf{B}] \Leftrightarrow [\mathbf{A},\mathbf{B}]_{ij} = [A_i,B_j] = A_iB_j - B_jA_i \Leftrightarrow \mathbf{AB}^T - (\mathbf{BA}^T)^T$, where $()^T$ represents matrix transposition.

   (a) Write the cross product $\mathbf{L}\times\mathbf{L}$ as a determinant and show that $\mathbf{L}\times\mathbf{L} = i\hbar\mathbf{L}$.
   Answer:

$$\begin{aligned} \mathbf{L}\times\mathbf{L} &= \begin{vmatrix} \mathbf{x} & \mathbf{y} & \mathbf{z} \\ L_x & L_y & L_z \\ L_x & L_y & L_z \end{vmatrix} \\ &= \mathbf{x}(L_yL_z - L_zL_y) - \mathbf{y}(L_xL_z - L_zL_x) + \mathbf{z}(L_xL_y - L_yL_x) \\ &= i\hbar(\mathbf{x}\,L_x + \mathbf{y}\,L_y + \mathbf{z}\,L_z) = i\hbar\mathbf{L} \end{aligned}$$

(b) Express $(\mathbf{L}\times\mathbf{L})_i$ in the Einstein notation and show that $(\mathbf{L}\times\mathbf{L})_i = i\hbar L_i$ for $i\in\{x,y,z\}$:
Answer A: By definition of the cross product we have

$$(\mathbf{L}\times\mathbf{L})_i = \varepsilon_{ijk}L_jL_k.$$

For $i=x$ the Levi-Civita tensor implies that the summations over j and k only give a nonzero contribution for $j,k\in\{y,z\}$

$$(\mathbf{L}\times\mathbf{L})_x = L_yL_z - L_zL_y = [L_y,L_z] = i\hbar L_x.$$

By cyclic permutation of the indices we find $(\mathbf{L}\times\mathbf{L})_y = i\hbar L_y$ and $(\mathbf{L}\times\mathbf{L})_z = i\hbar L_z$.
Answer B: In Einstein notation, the cross product is given by $(\mathbf{L}\times\mathbf{L})_i = \varepsilon_{ijk}L_jL_k$. Using the commutation relation $[L_j,L_k] = i\hbar\varepsilon_{mjk}L_m$ the cross product can be expressed in the form

$$(\mathbf{L}\times\mathbf{L})_i = \varepsilon_{ijk}L_jL_k = \varepsilon_{ijk}L_kL_j + i\hbar\varepsilon_{ijk}\varepsilon_{mjk}L_i = -(\mathbf{L}\times\mathbf{L})_i + 2i\hbar L_i,$$

which can be rewritten as

$$(\mathbf{L}\times\mathbf{L})_i = i\hbar L_i.$$

To obtained this result we used the relations $\varepsilon_{ijk}L_kL_j = -(\mathbf{L}\times\mathbf{L})_i$ and $\varepsilon_{ijk}\varepsilon_{mjk} = \varepsilon_{jki}\varepsilon_{jkm} = \delta_{kk}\delta_{im} - \delta_{km}\delta_{ik} = 3\delta_{im} - \delta_{im} = 2\delta_{im}$ (see Problem 1.1).

(c) Write the tensor $\mathbf{A}\mathbf{B}^T$ as a matrix and show that $[\mathbf{A},\mathbf{B}]=0$ if and only if all components of $\mathbf{A}$ commute with all components of $\mathbf{B}$.
Answer:

$$\mathbf{A}\mathbf{B}^{\mathbf{T}} = \begin{pmatrix} A_xB_x & A_xB_y & A_xB_z \\ A_yB_x & A_yB_y & A_yB_z \\ A_zB_x & A_zB_y & A_zB_z \end{pmatrix}$$

$$[\mathbf{A},\mathbf{B}] \equiv \mathbf{A}\mathbf{B}^T - (\mathbf{B}\mathbf{A}^T)^T = \begin{pmatrix} A_xB_x - B_xA_x & A_xB_y - B_yA_x & A_xB_z - B_zA_x \\ A_yB_x - B_xA_y & A_yB_y - B_yA_y & A_yB_z - B_yA_z \\ A_zB_x - B_xA_z & A_zB_y - B_zA_y & A_zB_z - B_zA_z \end{pmatrix}.$$

(d) Show that $[\mathbf{L},\mathbf{L}]\neq 0$. Recall that $[L_x,L_y] = i\hbar L_z$. Hence, not all components of $\mathbf{L}$ commute with each other. As a consequence $[\mathbf{L},\mathbf{L}]\neq 0$,

$$[\mathbf{L},\mathbf{L}] \equiv \begin{pmatrix} 0 & L_xL_y - L_yL_x & L_xL_z - L_zL_x \\ L_yL_x - L_xL_y & 0 & L_yL_z - L_yL_z \\ L_zL_x - L_xL_z & L_zL_y - L_zL_y & 0 \end{pmatrix} = \begin{pmatrix} 0 & i\hbar L_z & -i\hbar L_y \\ -i\hbar L_z & 0 & i\hbar L_x \\ i\hbar L_y & -i\hbar L_x & 0 \end{pmatrix} \neq 0.$$

(e) Give an expression for $[\mathbf{L},\mathbf{L}]_{ij}$ in the Einstein notation:

$$[\mathbf{L},\mathbf{L}]_{ij} = L_iL_j - L_jL_i = [L_i,L_j] = \varepsilon_{ijk}i\hbar L_k.$$

(f) (0.4) Calculate $\left[\mathbf{L}^2,\mathbf{L}^2\right]$:

$$\left[\mathbf{L}^2,\mathbf{L}^2\right] = (L_x^2+L_y^2+L_z^2)(L_x^2+L_y^2+L_z^2) - (L_x^2+L_y^2+L_z^2)(L_x^2+L_y^2+L_z^2) = 0.$$

5. **Tensor products of state vectors:** Consider two angular momenta, $\boldsymbol{j}_1$ and $\boldsymbol{j}_2$, acting in vector spaces of dimension $d_1 = 2$ and $d_2 = 3$, respectively (i.e., $j_1 = \frac{1}{2}$ and $j_2 = 1$). The corresponding eigenstates are given by

$$|\tfrac{1}{2}, +\tfrac{1}{2}\rangle = \begin{pmatrix} 1 \\ 0 \end{pmatrix}, \qquad |\tfrac{1}{2}, -\tfrac{1}{2}\rangle = \begin{pmatrix} 0 \\ 1 \end{pmatrix} \tag{Q.5}$$

and

$$|1, +1\rangle = \begin{pmatrix} 1 \\ 0 \\ 0 \end{pmatrix}, \qquad |1, 0\rangle = \begin{pmatrix} 0 \\ 1 \\ 0 \end{pmatrix}, \qquad |1, -1\rangle = \begin{pmatrix} 0 \\ 0 \\ -1 \end{pmatrix}. \tag{Q.6}$$

In the *uncoupled* representation the eigenstate $|\frac{1}{2}, +\frac{1}{2}; 1, 0\rangle$ is given by the tensor product

$$|\tfrac{1}{2}, +\tfrac{1}{2}; 1, 0\rangle = |\tfrac{1}{2}, +\tfrac{1}{2}\rangle \otimes |1, 0\rangle = \begin{pmatrix} 1 \\ 0 \end{pmatrix} \otimes \begin{pmatrix} 0 \\ 1 \\ 0 \end{pmatrix} = \begin{pmatrix} 0 \\ 1 \\ 0 \\ 0 \\ 0 \\ 0 \end{pmatrix}.$$

Note that for the doublet state $|\frac{1}{2}, +\frac{1}{2}\rangle$ the tensor product $|\frac{1}{2}, +\frac{1}{2}\rangle \otimes |1, 0\rangle$ provides a three-dimensional subspace for the triplet state $|1, 0\rangle$. Analogously, for the triplet state $|1, 0\rangle$, the tensor product $|1, 0\rangle \otimes |\frac{1}{2}, +\frac{1}{2}\rangle$ provides a two-dimensional subspace for the doublet state $|\frac{1}{2}, +\frac{1}{2}\rangle$. In both ways we obtain a 6-dimensional Hilbert space (for the tensors $\boldsymbol{j}_1 \otimes \boldsymbol{j}_2$ and $\boldsymbol{j}_2 \otimes \boldsymbol{j}_1$, respectively). In the *uncouple*d representation the *stretched state* is given by $|j_1, j_1; j_2, j_2\rangle = |j_1, j_1\rangle \otimes |j_2, j_2\rangle$; i.e., for $j_1 = \frac{1}{2}$ and $j_2 = 1$ this corresponds to $|\frac{1}{2}, +\frac{1}{2}; 1, 1\rangle = |\frac{1}{2}, +\frac{1}{2}\rangle \otimes |1, 1\rangle$. The tensor product is a so-called ordered product.

(a) Do the states $|\frac{1}{2}, +\frac{1}{2}\rangle$ and $|1, 0\rangle$ commute under the tensor product?
Answer: No

$$|\tfrac{1}{2}, +\tfrac{1}{2}\rangle \otimes |1, 0\rangle = \begin{pmatrix} 1 \\ 0 \end{pmatrix} \otimes \begin{pmatrix} 0 \\ 1 \\ 0 \end{pmatrix} = \begin{pmatrix} 0 \\ 1 \\ 0 \\ 0 \\ 0 \\ 0 \end{pmatrix} \neq \begin{pmatrix} 0 \\ 0 \\ 1 \\ 0 \\ 0 \\ 0 \end{pmatrix} = \begin{pmatrix} 0 \\ 1 \\ 0 \end{pmatrix} \otimes \begin{pmatrix} 1 \\ 0 \end{pmatrix} = |1, 0\rangle \otimes |\tfrac{1}{2}, +\tfrac{1}{2}\rangle.$$

(b) Do the states $|\frac{1}{2}, +\frac{1}{2}\rangle$ and $|1, 1\rangle$ commute under the tensor product?
Answer: Yes, $|j_1, j_1\rangle$ and $|j_2, j_2\rangle$ always commute

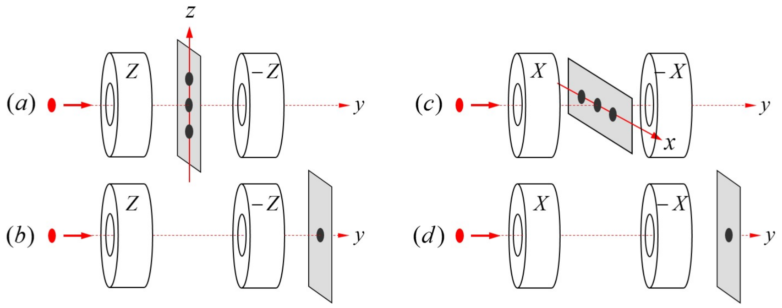
$$|\tfrac{1}{2}, +\tfrac{1}{2}\rangle \otimes |1, 1\rangle = \begin{pmatrix} 1 \\ 0 \end{pmatrix} \otimes \begin{pmatrix} 1 \\ 0 \\ 0 \end{pmatrix} = \begin{pmatrix} 1 \\ 0 \\ 0 \\ 0 \\ 0 \\ 0 \end{pmatrix} = \begin{pmatrix} 1 \\ 0 \\ 0 \end{pmatrix} \otimes \begin{pmatrix} 1 \\ 0 \end{pmatrix} = |1, 1\rangle \otimes |\tfrac{1}{2}, +\tfrac{1}{2}\rangle.$$

(c) The tensor product is an ordered product because the factors do not commute.

Q.7 Problem set 4

PROBLEMS CHAPTER 3 AND 4

Problem set 4: Ramsey machines!



Figuur Q.1: Sketch of Ramsey machines: (a) measuring vertical polarization; (b) refocused beam with vertical polarizers; (c) measuring horizontal polarization; (d) refocused beam with horizontal polarizers

In Fig. Q.1 you find a sketch of so-called Ramsey machines, which are sophisticated Stern-Gerlach analyzers consisting of magnetic lenses. When a beam of $j = 1$ atoms enters a Z analyzer we can observe 3 spots along the z direction by putting a detection screen (see Fig. Q.1-a). Putting a second analyzer, a $-Z$ analyzer, the beam is refocused as we can observe by putting a detection screen behind both analyzers (see Fig. Q.1-b). In Fig. Q.1-c/d we show similar machines but now with X analyzers (which are the same as Z analyzers rotated over 90 degrees about the beam axis). Let us suppose that the beam is *unpolarized*; i.e., the beam consists of ensemble of atoms in randomly chosen states of the $j = 1$ system. *Hint:* An arbitrary *pure* state is given by (up to a global phase factor)

$$|\chi\rangle = \sum_{m=-j}^{j} |j,m\rangle\langle jm|\chi\rangle.$$

Hence for $j = 1$ an *arbitrary* state can be written in the form

$$|\chi\rangle = \sum_{m=-1}^{1} a_m|j,m\rangle,$$

where the Parseval relation has to be satisfied

$$\sum_{m=-1}^{1} |a_m|^2 = 1.$$

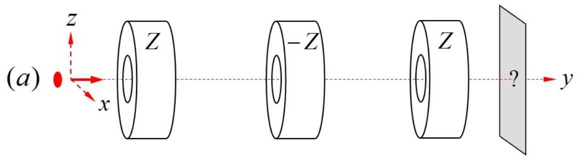
Let us consider an atom which happens to be in the state $|\chi\rangle$. The probability to observe this atom in the state $|j,m\rangle$ is $|a_m|^2$. In the unpolarized ensemble $|a_1|^2$, $|a_0|^2$ and $|a_{-1}|^2$ will take random values between 0 and 1, subject to the constraint of the Parseval relation; i.e, the basis $\{|j,m\rangle\}$ represents an ensemble of states with equal weight $w_m = \frac{1}{3}$ (called a statistical mixture or *mixed* state) that can be represented by the following density matrix - see Eq. (F.110)

$$\varrho = \tfrac{1}{3} \sum_{m=-j}^{j} |j,m\rangle\,\langle j,m| = \tfrac{1}{3}\begin{pmatrix} 1\,0\,0 \\ 0\,1\,0 \\ 0\,0\,1 \end{pmatrix}.$$

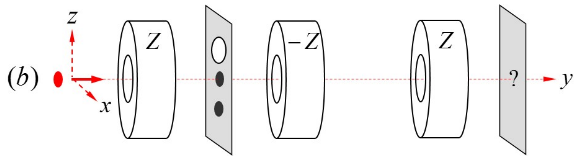
.

Questions:

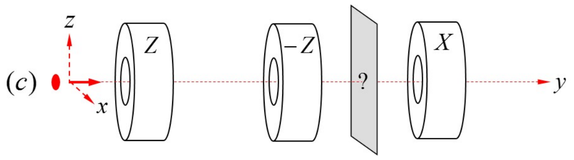
1. Below we show Ramsey machine (a) with 3 analyzers $(Z, -Z, Z)$. Calculate the polarization (of the ensemble) in the z direction and sketch what you expect to observe by putting a screen at the end of the beam line.



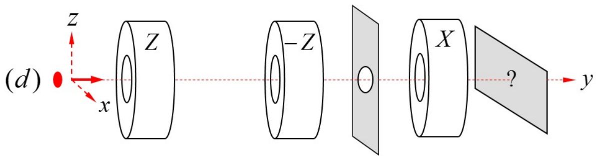
2. In Ramsey machine (b) we block 2 of the 3 spots between the Z and $-Z$ analyzers (see below). Calculate the polarization in the z direction and sketch what you expect to observe by putting a screen at the end of the beam line.



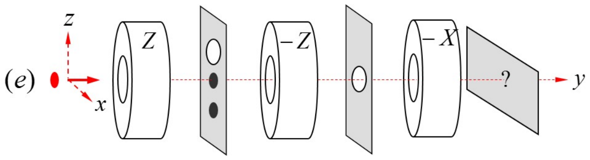
3. In Ramsey machine (c) we have a screen between the $-Z$ and X analyzers (see below). Sketch what you expect to observe on the screen between the $-Z$ and X analyzers.



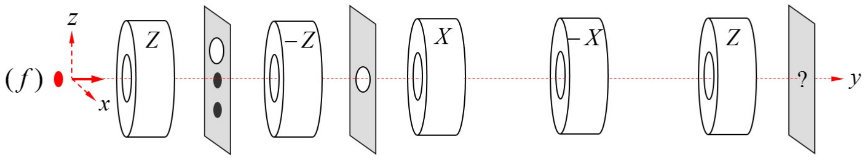
4. In Ramsey machine (d) we have an on-axis diaphragm between the $-Z$ and X analyzers (see below). Calculate the polarization in the x direction and sketch what you expect to observe by putting a screen at the end of the beam line.



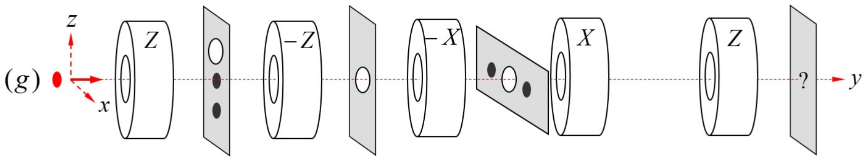
5. In Ramsey machine (e) we block 2 of the 3 spots between the Z and $-Z$ analyzers and keep the on-axis diaphragm between the $-Z$ and X analyzers (see below). Calculate the polarization in the x direction and sketch what you expect to observe by putting a screen at the end of the beam line.



6. In Ramsey machine (f) we block 2 of the 3 spots between the Z and $-Z$ analyzers and keep the on-axis diaphragm between the $-Z$ and X analyzers (see below). Calculate the polarization in the z direction and sketch what you expect to observe by putting a screen at the end of the beam line.



7. In Ramsey machine (g) we again block 2 of the 3 spots between the Z and $-Z$ analyzers, keep the on-axis diaphragm, and block 2 of the 3 spots between the X and $-X$ analyzers (see below). Calculate the polarization in the z direction and sketch what you expect to observe by \setcounter{figure}{0} putting a screen at the end of the beam line.



In 2019 not part of the problem set

1. (2.0) *Quantum Information Processing* deals with gate operations on *quantum bits* (*qubits*) in a *two-dimensional Hilbert space.* The qubits are state vectors in a 2D Hilbert space with the eigenstates denoted by

$$|0\rangle = \begin{pmatrix} 1 \\ 0 \end{pmatrix}, \quad |1\rangle = \begin{pmatrix} 0 \\ 1 \end{pmatrix}.$$

Note that the qubit map one-to-one on the states $|0\rangle \equiv |\uparrow\rangle \equiv |1/2, 1/2\rangle$ and $|1\rangle \equiv |\downarrow\rangle \equiv |1/2, -1/2\rangle$ of a spin $-1/2$ system. The gate operations are unitary operations. The basic examples of quantum gate operations that act on a single qubit are the gates X, Y and Z, which map one-to-one on the Pauli matrices,

$$\sigma_x = X = \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}, \quad \sigma_y = Y = \begin{pmatrix} 0 & -i \\ i & 0 \end{pmatrix}, \quad \sigma_z = Z = \begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix}.$$

Other gate operations are the *identity* $\mathbb{1}$,

$$\mathbb{1} \equiv \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix},$$

the *Hademard gate*

$$H \equiv \sqrt{\tfrac{1}{2}} \begin{pmatrix} 1 & 1 \\ 1 & -1 \end{pmatrix},$$

the *phase gate*

$$S \equiv \begin{pmatrix} 1 & 0 \\ 0 & i \end{pmatrix},$$

and the "$\pi/8$ *phase gate*"

$$T \equiv \begin{pmatrix} 1 & 0 \\ 0 & e^{i\pi/4} \end{pmatrix}.$$

Answer the following questions:

(a) (0.4) Show that $X^2 + Y^2 + Z^2 \neq \mathbb{1}$; calculate $X^2 + Y^2 + Z^2$.

(b) (0.4) Show that $H = (X + Z)/\sqrt{2}$.

(c) (0.4) Show that $\mathbb{1} = H^2$.

(d) (0.4) Show that $S = T^2$

(e) Calculate $X|0\rangle$ and describe the corresponding operation on the Bloch sphere.

(f) Calculate $Y|0\rangle$ and describe the corresponding operation on the Bloch sphere.

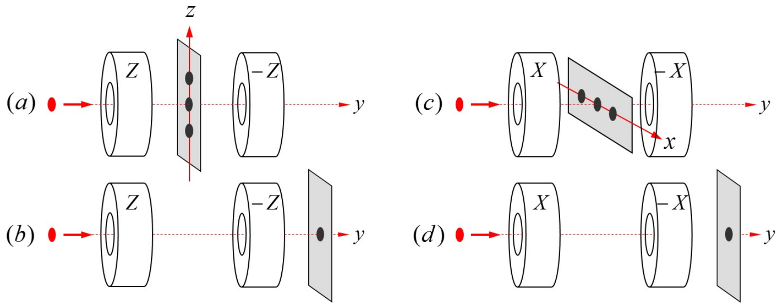
(g) Calculate $Z|0\rangle$ and describe the corresponding operation on the Bloch sphere.

(h) Calculate $H|0\rangle$ and describe the corresponding operation on the Bloch sphere.

Q.8 Problem set 4 - solutions

SOLUTIONS PROBLEMS CHAPTER 3 AND 4

Problem set 4: Ramsey machines!



Figuur Q.1: Sketch of Ramsey machines: (a) measuring vertical polarization; (b) refocused beam with vertical polarizers; (c) measuring horizontal polarization; (d) refocused beam with horizontal polarizers

In Fig. Q.1 you find a sketch of so-called Ramsey machines, which are sophisticated Stern-Gerlach analyzers consisting of magnetic lenses. When a beam of $j = 1$ atoms enters a Z analyzer we can observe 3 spots along the z direction by putting a detection screen (see Fig. Q.1-a). Putting a second analyzer, a $-Z$ analyzer, the beam is refocused as we can observe by putting a detection screen behind both analyzers (see Fig. Q.1-b). In Fig. Q.1-c/d we show similar machines but now with X analyzers (which are the same as Z analyzers rotated over 90 degrees about the beam axis). Let us suppose that the beam is *unpolarized*; i.e., the beam consists of ensemble of atoms in randomly chosen states of the $j = 1$ system. *Hint:* An arbitrary *pure* state is given by (up to a global phase factor) \setcounter{figure}{0}

$$|\chi\rangle = \sum_{m=-j}^{j} |j, m\rangle\langle jm|\chi\rangle.$$

Hence for $j = 1$ an *arbitrary* state can be written in the form

$$|\chi\rangle = \sum_{m=-1}^{1} a_m |j, m\rangle,$$

where the Parseval relation has to be satisfied

$$\sum_{m=-1}^{1} |a_m|^2 = 1.$$

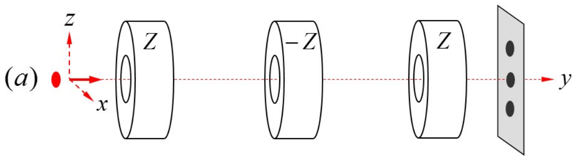
Let us consider an atom which happens to be in the state $|\chi\rangle$. The probability to observe this atom in the state $|j, m\rangle$ is $|a_m|^2$. In the unpolarized beam $|a_1|^2$, $|a_0|^2$ and $|a_{-1}|^2$ will take random values between 0 and 1, subject to the constraint of the Parseval relation; i.e, the basis $\{|j, m\rangle\}$ represents an ensemble of states with equal weight $w_m = \frac{1}{3}$ (called a statistical mixture or *mixed* state) that can be represented by the following density matrix - see Eq. (F.110)

$$\varrho = \tfrac{1}{3} \sum_{m=-j}^{j} |j, m\rangle \langle j, m| = \tfrac{1}{3} \begin{pmatrix} 1\,0\,0 \\ 0\,1\,0 \\ 0\,0\,1 \end{pmatrix}.$$

Questions:

1. Below we show Ramsey machine (a) with 3 analyzers $(Z, -Z, Z)$. Calculate the polarization (of the ensemble) in the z direction and sketch what you expect to observe by putting a screen

at the end of the beam line. Let us consider an atom which happens to be in the state $|\chi\rangle$.
Answer 1:



Only at the screen we do a measurement. As the initial beam is unpolarized we observe three spots. The $-Z$ analyzer undoes the action of the first Z analyzer, so we observe the effect of the last analyzer, which shows equal population of $m_j = -1$, $m_j = 0$, and $m_j = +1$. The polarization in the z direction (of a $j = 1$ atoms) is given by

$$P_z = \langle\chi|J_z/\hbar|\chi\rangle = \sum_{m=-1}^{1} |a_m|^2 m = |a_1|^2 - |a_{-1}|^2.$$

This value can vary between 1 and -1. Now suppose $|a_1|^2 = a$ and $|a_{-1}|^2 = b$. In an unpolarized beam, for every atom with $|a_1|^2 = a$ and $|a_{-1}|^2 = b$ there will be another atom with $|a_1|^2 = b$ and $|a_{-1}|^2 = a$. Hence, the ensemble average $\bar{P}_z = 0$. What can be said about the relative brightness of the three spots? Since all combinations of $|a_1|^2$, $|a_0|^2$ and $|a_{-1}|^2$ (satisfying the constraint of the Parseval relation) are equally probable we know that the statistical averages must be equal, $\langle|a_1|^2\rangle = \langle|a_0|^2\rangle = \langle|a_{-1}|^2\rangle$; i.e., the three spots are equally bright.
Answer 2:
The density matrix describing the unpolarized beam in the basis of the $|j, m\rangle$ eigenstates of J_z and $\mathbf{J}^2$ is:

$$\varrho = \tfrac{1}{3}\sum_{m=-j}^{j} |j,m\rangle\langle j,m| = \tfrac{1}{3}\begin{pmatrix}1&0&0\\0&1&0\\0&0&1\end{pmatrix}.$$

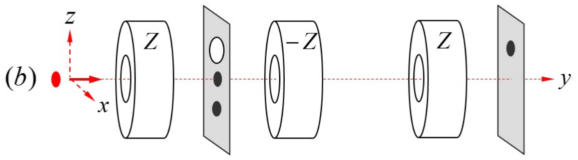
Note that tr $\varrho^2 = \frac{1}{3} < 1$, which is an indicator that the state is mixed. The polarization in the z direction is given by:

$$\langle\!\langle J_z/j\hbar\rangle\!\rangle = \mathrm{tr}(\varrho J_z)/j\hbar = 0.$$

The beam is unpolarized in the z direction, as expected. Note that the same holds for the x and y directions, which is readily verified :

$$\langle\!\langle J_x/j\hbar\rangle\!\rangle = \langle\!\langle J_y/j\hbar\rangle\!\rangle = \mathrm{tr}(\varrho J_x)/j\hbar = \mathrm{tr}(\varrho J_y)/j\hbar = 0.$$

2. In Ramsey machine (b) we block 2 of the 3 spots between the Z and $-Z$ analyzers (see below). Calculate the polarization in the z direction and sketch what you expect to observe by putting a screen at the end of the beam line.
Answer 1:



By blocking two of the three spots we do a measurement that polarizes the beam into the state with $m_j = +1$ with respect to the z quantization axis. The $-Z$ analyzer focuses the beam and the second Z analyzer measures the polarization in the z direction. We calculate

$$\langle J_z/j\hbar\rangle_{jj} = \langle j,j|J_z/j\hbar|j,j\rangle = 1.$$

So, the beam is fully polarized in the z direction; i.e., we observe 1 spot.
Answer 2:
By blocking two of the three spots we do a measurement that polarizes the beam into the *pure* state with $m_j = +j$ with respect to the z quantization axis. The density matrix describing the beam after the blocker is

$$\rho = |j,j\rangle\langle j,j| = \begin{pmatrix} 1 & 0 & 0 \\ 0 & 0 & 0 \\ 0 & 0 & 0 \end{pmatrix}.$$

Note that $\rho^2 = \rho$, as required for a pure state. The polarization in the z direction is now given by:

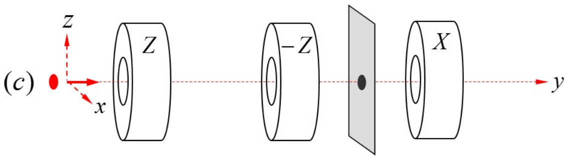
$$\langle J_z/j\hbar\rangle = \mathrm{tr}(\rho J_z)/j\hbar = 1.$$

The beam is fully polarized in the z direction. Note that:

$$\langle J_x/j\hbar\rangle = \langle J_y/j\hbar\rangle = \mathrm{tr}(\rho J_x)/j\hbar = \mathrm{tr}(\rho J_y)/j\hbar = 0.$$

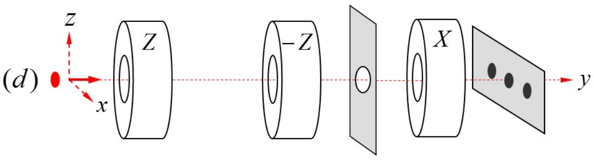
So the beam is still unpolarized in the x and y directions.

3. In Ramsey machine (c) we have a screen between the $-Z$ and X analyzers (see below). Sketch what you expect to observe on the screen between the $-Z$ and X analyzers.
Answer:



The $-Z$ analyzer undoes the action of the Z analyzer, so we observe the unpolarized incident beam focused onto one spot (see Fig. Q.1-b/d).

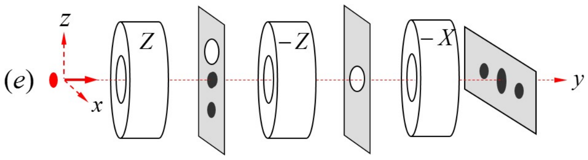
4. In Ramsey machine (d) we have an on-axis diaphragm between the $-Z$ and X analyzers (see below). Calculate the polarization in the x direction and sketch what you expect to observe by putting a screen at the end of the beam line.
Answer:



The $-Z$ analyzer undoes the action of the Z analyzer, so the unpolarized beam passes through the diaphragm. This problem is the same as question 1. We simply analyze the unpolarized initial beam with the detector rotated over 90° about the beam axis. The diaphragm is of no consequence because the probability to detect the focused beam on the screen around the orifice is zero.

5. In Ramsey machine (e) we block 2 of the 3 spots between the Z and $-Z$ analyzers and keep the on-axis diaphragm between the $-Z$ and X analyzers (see below). Calculate the polarization in the x direction and sketch what you expect to observe by putting a screen at the end of the beam line.

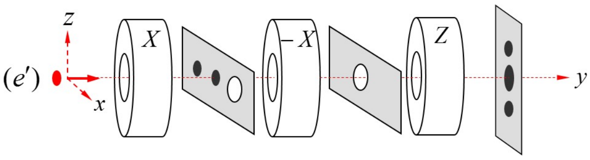
Answer 1:



By blocking two of the three spots we do a measurement that polarizes the beam into the state with $m_j = +1$ with respect to the z quantization axis. Having defined the z axis we know that the x and y axes can be defined as perpendicular axes of a right-handed coordinate system. In the Figure an $-X$ analyzer analyzes the effect of the Z analyzer. Apparently, the $+y$ direction was chosen along beam axis (we could equally well choose the x axis along the beam direction and call the analyzer a Y analyzer). We calculate for the polarization

$$\langle J_x/j\hbar\rangle_{jj} = \langle j,j|J_x/j\hbar|j,j\rangle = 0.$$

Hence, under the given convention the beam is unpolarized in the X direction. To determine the intensity of the spots we need more information about the state $|j,j\rangle$ with respect to the quantization axis in the x direction. To obtain this we rotate the apparatus clockwise over 90° about the beam axis as shown in the figure below.



We know that the beam passing the first blocker should satisfy the relation

$$J_x|\chi\rangle = +\hbar|\chi\rangle.$$

Expressing J_x with respect to the z quantization axis, see Eq. (3.307), this becomes

$$\sqrt{1/2}\hbar \begin{pmatrix} 0\,1\,0 \\ 1\,0\,1 \\ 0\,1\,0 \end{pmatrix} \begin{pmatrix} a \\ b \\ c \end{pmatrix} = \hbar \begin{pmatrix} a \\ b \\ c \end{pmatrix},$$

where a, b and c are the coefficients for the decomposition of the state $|\chi\rangle$ with respect to the z axis. So, we have to solve the set of equations

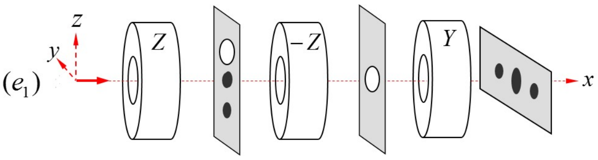
$$\begin{aligned} \sqrt{1/2}b &= a \\ \sqrt{1/2}(a+c) &= b \\ \sqrt{1/2}b &= c. \end{aligned}$$

Under the constraint $|a|^2 + |b|^2 + |c|^2 = 1$ we obtain (up to a global phase factor) $a = c = 1/2$ and $b = \sqrt{1/2}$. Hence, we observe 3 spots and the middle one is twice as bright as the others.

Now we rotate the machine back to the original position and conclude that we should observe 3 spots along the z direction and the middle one is twice as bright as the others (this result confirms zero polarization in the detection direction).
Note that the state $|\chi\rangle$ can also be obtained by unitary transformation of the state $|j,j\rangle = |1,1\rangle$. In Eq. (3.303a) we show the matrix for the unitary transformation $D^1(0,\pi/2,0)$, which corresponds to a clockwise over 90° about the y-axis. Applying this transformation we find

$$|\chi\rangle = D^1(0,\pi/2,0)\,|1,1\rangle_z = \begin{pmatrix} \frac{1}{2} & -\sqrt{\frac{1}{2}} & \frac{1}{2} \\ \sqrt{\frac{1}{2}} & 0 & -\sqrt{\frac{1}{2}} \\ \frac{1}{2} & \sqrt{\frac{1}{2}} & \frac{1}{2} \end{pmatrix} \begin{pmatrix} 1 \\ 0 \\ 0 \end{pmatrix} = \begin{pmatrix} \frac{1}{2} \\ \sqrt{\frac{1}{2}} \\ \frac{1}{2} \end{pmatrix}.$$

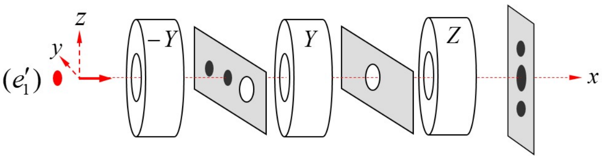
Answer 2:



We repeat the calculation for another choice of the cartesian coordinate system. Note that what used to be a $-X$ machine is now called a Y machine. We calculate for the polarization

$$\langle J_y/j\hbar\rangle_{jj} = \langle j,j|J_y/j\hbar|j,j\rangle = 0.$$

Hence, under the new convention the beam is unpolarized in the Y direction. To determine the intensity of the spots we need more information about the state $|j,-j\rangle$ with respect to the quantization axis in the y direction. To obtain this we rotate again the apparatus clockwise over 90° about the beam axis as shown in the figure below.



We know that the beam passing the first blocker should satisfy the relation

$$J_y|\chi\rangle = -\hbar|\chi\rangle.$$

Expressing J_y with respect to the z quantization axis, see Eq. (3.307), this becomes

$$\sqrt{1/2}i\hbar \begin{pmatrix} 0 & -1 & 0 \\ 1 & 0 & -1 \\ 0 & 1 & 0 \end{pmatrix} \begin{pmatrix} a \\ b \\ c \end{pmatrix} = -\hbar \begin{pmatrix} a \\ b \\ c \end{pmatrix},$$

where a, b and c are the coefficients for the decomposition of the state $|\chi\rangle$ with respect to the z axis. Thus we have to solve the set of equations-

$$\begin{aligned} -\sqrt{1/2}ib &= -a \\ -\sqrt{1/2}i(a-c) &= -b \\ \sqrt{1/2}ib &= -c. \end{aligned}$$

Under the constraint $|a|^2+|b|^2+|c|^2=1$ we obtain (up to a global phase factor) $-c=a=i/2$ and $b=\sqrt{1/2}$. Hence, we predict 3 spots and the middle one is twice as bright as the others, just as we found for the other choice of coordinates. Note that the choice of coordinate system affects the relative phases of the components but this does not affect the result of the measurement.

Answer 3:

By blocking two of the three spots we do a measurement that polarizes the beam into the state with $m_j=+j=1$ with respect to the z quantization axis. The density matrix describing the beam after the blocker is thus:

$$\rho_{m_j}=|j,j\rangle\langle j,j|=\begin{pmatrix}1&0&0\\0&0&0\\0&0&0\end{pmatrix}.$$

The polarization in the x direction is given by:

$$\langle J_x/j\hbar\rangle=\mathrm{tr}(\rho J_x)/j\hbar=0.$$

So the beam is unpolarized in the x direction. To calculate the intensity of the spots we first rotate the system over 90° about the beam axis. The corresponding unitary transformation is $|\chi\rangle=D^1(0,\pi/2,0)\,|1,1\rangle_z$ and was calculated under *Answer 1.* The corresponding density matrix is

$$\rho=|\chi\rangle\langle\chi|=\begin{pmatrix}\frac{1}{2}\\\sqrt{\frac{1}{2}}\\\frac{1}{2}\end{pmatrix}\left(\tfrac{1}{2},\sqrt{\tfrac{1}{2}},\tfrac{1}{2}\right)=\frac{1}{4}\begin{pmatrix}1&\sqrt{2}&1\\\sqrt{2}&2&\sqrt{2}\\1&\sqrt{2}&1\end{pmatrix}.$$

Note that $\rho^2=\rho$ as required for a pure state. To calculate the intensity of the spots we ask for $\langle\rho_m\rangle=\mathrm{tr}\,(\rho\,\rho_m)$, where $m\in\{1,0,-1\}$. The ρ_{m_j} are given by

$$\rho_1=\begin{pmatrix}1&0&0\\0&0&0\\0&0&0\end{pmatrix};\quad\rho_0=\begin{pmatrix}0&0&0\\0&1&0\\0&0&0\end{pmatrix};\quad\rho_{-1}=\begin{pmatrix}0&0&0\\0&0&0\\0&0&1\end{pmatrix}.$$

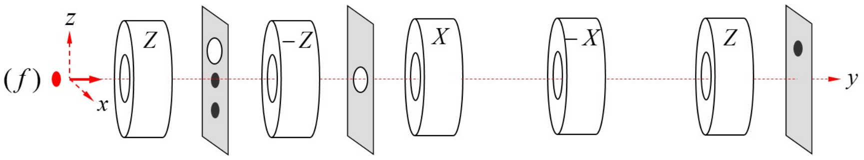
Thus we find

$$\rho\,\rho_1=\frac{1}{4}\begin{pmatrix}1&0&0\\\sqrt{2}&0&0\\1&0&0\end{pmatrix};\quad\rho\,\rho_0=\frac{1}{4}\begin{pmatrix}0&\sqrt{2}&0\\0&2&0\\0&\sqrt{2}&0\end{pmatrix};\quad\rho\,\rho_{-1}=\frac{1}{4}\begin{pmatrix}0&0&1\\0&0&\sqrt{2}\\0&0&1\end{pmatrix}.$$

Tracing these matrices we arrive at $\mathrm{tr}\,(\rho\,\rho_1)=\frac{1}{4}$, $\mathrm{tr}\,(\rho\,\rho_0)=\frac{1}{2}$ and $\mathrm{tr}\,(\rho\,\rho_{-1})=\frac{1}{4}$.

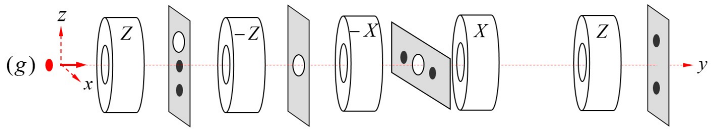
6. In Ramsey machine (f) we block 2 of the 3 spots between the Z and $-Z$ analyzers and keep the on-axis diaphragm between the $-Z$ and X analyzers (see below). Calculate the polarization in the z direction and sketch what you expect to observe by putting a screen at the end of the beam line.

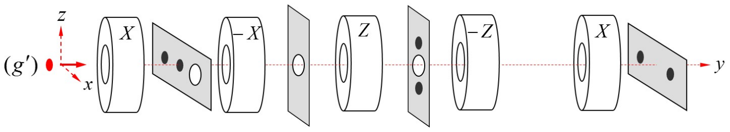
Answer:



The X and $-X$ analyzers do not effect the beam (no measurement). Therefore, this question reduces to question 2.

7. In Ramsey machine (g) we again block 2 of the 3 spots between the Z and $-Z$ analyzers, keep the on-axis diaphragm, and block 2 of the 3 spots between the X and $-X$ analyzers (see below). Calculate the polarization in the z direction and sketch what you expect to observe by putting a screen at the end of the beam line.
Answer:





Up to the third screen we have the same situation as in question 5. To calculate the polarization in the x direction we rotate the machine clockwise over 90° about the beam axis. In this way we obtain machine (g'). In this case we have to calculate:

$$\langle J_x/j\hbar\rangle_{j0} = \langle j,0|J_x/j\hbar|j,0\rangle = 0.$$

Hence, the beam is unpolarized in the x direction. Now we rotate the machine back to the original position and conclude that the beam is unpolarized in the z direction.
What about the spots? For this we stick to (g). We know that the beam passing the first diaphragm should satisfy the relation

$$J_x|\chi\rangle = 0\hbar|\chi\rangle.$$

Expressing J_x with respect to the z quantization axis, see Eq. (3.307), this becomes

$$\sqrt{1/2}\hbar\begin{pmatrix}0\,1\,0\\1\,0\,1\\0\,1\,0\end{pmatrix}\begin{pmatrix}a\\b\\c\end{pmatrix} = \begin{pmatrix}0\\0\\0\end{pmatrix}.$$

Thus we have to solve the set of equations

$$\begin{aligned}\sqrt{1/2}b &= 0\\ \sqrt{1/2}(a+c) &= 0\\ \sqrt{1/2}b &= 0.\end{aligned}$$

Under the constraint $|a|^2 + |b|^2 + |c|^2 = 1$ we obtain (up to phase factors) $a = -c = \sqrt{1/2}$ and $b = 0$. Hence, we observe 2 spots with the middle one lacking (this result confirms zero polarization in the detection direction).

In 2019 not part of the problem set

1. (2.0) *Quantum Information Processing* deals with gate operations on *quantum bits* (qubit*s*) in a *two-dimensional Hilbert space.* The qubits are state vectors in a 2D Hilbert space with the eigenstates denoted by
$$|0\rangle = \begin{pmatrix} 1 \\ 0 \end{pmatrix}, \quad |1\rangle = \begin{pmatrix} 0 \\ 1 \end{pmatrix}.$$
Note that the qubits map one-to-one on the states $|0\rangle \equiv |\uparrow\rangle \equiv |1/2, 1/2\rangle$ and $|1\rangle \equiv |\downarrow\rangle \equiv |1/2, -1/2\rangle$ of a spin $-1/2$ system. The gate operations are unitary operations. The basic examples of quantum gate operations that act on a single qubit are the gates X, Y *and* Z, which map one-to-one on the Pauli matrices,
$$\sigma_x = X = \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}, \quad \sigma_y = Y = \begin{pmatrix} 0 & -i \\ i & 0 \end{pmatrix}, \quad \sigma_z = Z = \begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix}.$$
Other gate operations are the *identity* $\mathbb{1}$,
$$\mathbb{1} \equiv \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix},$$
the *Hademard gate*
$$H \equiv \sqrt{\tfrac{1}{2}} \begin{pmatrix} 1 & 1 \\ 1 & -1 \end{pmatrix},$$
the *phase gate*
$$S \equiv \begin{pmatrix} 1 & 0 \\ 0 & i \end{pmatrix},$$
and the "$\pi/8$ *phase gate*"
$$T \equiv \begin{pmatrix} 1 & 0 \\ 0 & e^{i\pi/4} \end{pmatrix}.$$
Answer the following questions:

   (a) (0.4) Show that $X^2 + Y^2 + Z^2 \neq \mathbb{1}$; calculate $X^2 + Y^2 + Z^2$.
   Answer: Using the definitions of X, Y and Z we find
$$\begin{aligned} X^2 + Y^2 + Z^2 &= \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}\begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix} + \begin{pmatrix} 0 & -i \\ i & 0 \end{pmatrix}\begin{pmatrix} 0 & -i \\ i & 0 \end{pmatrix} + \begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix}\begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix} \\ &= \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix} + \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix} + \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix} = 3\begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix}. \end{aligned}$$

   (b) (0.4) Show that $H = (X + Z)/\sqrt{2}$.
   Answer: Using the definitions of X and Z we find
$$\sqrt{\frac{1}{2}}(X + Z) = \sqrt{\frac{1}{2}}\begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix} + \sqrt{\frac{1}{2}}\begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix} = \sqrt{\frac{1}{2}}\begin{pmatrix} 1 & 1 \\ 1 & -1 \end{pmatrix} = H.$$

   (c) (0.4) Show that $\mathbb{1} = H^2$.
   Answer: Using the definition of H we calculate
$$H^2 = \frac{1}{2}\begin{pmatrix} 1 & 1 \\ 1 & -1 \end{pmatrix}\begin{pmatrix} 1 & 1 \\ 1 & -1 \end{pmatrix} = \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix} = \mathbb{1}.$$

(d) (0.4) Show that $S = T^2$.
Answer: Using the definition of T and S we find

$$T^2 = \begin{pmatrix} 1 & 0 \\ 0 & e^{i\pi/4} \end{pmatrix} \begin{pmatrix} 1 & 0 \\ 0 & e^{i\pi/4} \end{pmatrix} = \begin{pmatrix} 1 & 0 \\ 0 & i \end{pmatrix} = S.$$

(e) Calculate $X|0\rangle$ and describe the corresponding operation on the Bloch sphere.
Answer:

$$X|0\rangle = \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix} \begin{pmatrix} 1 \\ 0 \end{pmatrix} = \begin{pmatrix} 0 \\ 1 \end{pmatrix} = |1\rangle.$$

This corresponds to a rotation over π on the Bloch sphere about the $\hat{y}$ direction $(\theta, \phi) = (\pi, 0)$.

(f) Calculate $Y|0\rangle$ and describe the corresponding operation on the Bloch sphere.
Answer:

$$Y|0\rangle = \begin{pmatrix} 0 & -i \\ i & 0 \end{pmatrix} \begin{pmatrix} 1 \\ 0 \end{pmatrix} = \begin{pmatrix} 0 \\ i \end{pmatrix} = i|1\rangle.$$

This corresponds to a rotation π on the Bloch sphere about the $\hat{x}$ direction $(\theta, \phi) = (\pi, \pi/2)$.

(g) Calculate $Z|0\rangle$ and describe the corresponding operation on the Bloch sphere.
Answer:

$$Z|0\rangle = \begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix} \begin{pmatrix} 1 \\ 0 \end{pmatrix} = \begin{pmatrix} 1 \\ 0 \end{pmatrix} = |0\rangle.$$

It is clear from the definition of Z that this operator is *not* the identity; Z corresponds to a rotation over π on the Bloch sphere about the $\hat{z}$ direction.

(h) Calculate $H|0\rangle$ and describe the corresponding operation on the Bloch sphere.
Answer:

$$H|0\rangle = \sqrt{\frac{1}{2}} \begin{pmatrix} 1 & 1 \\ 1 & -1 \end{pmatrix} \begin{pmatrix} 1 \\ 0 \end{pmatrix} = \sqrt{\frac{1}{2}} \begin{pmatrix} 1 \\ 1 \end{pmatrix} = \sqrt{\tfrac{1}{2}}(|0\rangle + |1\rangle).$$

This corresponds to a rotation over π about the $(\hat{x} + \hat{z})/\sqrt{2}$ direction on the Bloch sphere. Note that it cannot be a rotation about the $\mathbf{\hat{y}}$ axis because $H^2 = \mathbb{1}$. Note that $H|\uparrow\rangle_y = |\uparrow\rangle_{-y}$.

Q.9 Problem set 5

PROBLEMS CHAPTER 4

1. **The LSJ commute:** The Schrödinger Hamiltonian can be written as

$$H_0 = \frac{1}{2\mu}\left(p_r^2 + \frac{\mathbf{L}^2}{r^2}\right) - \frac{Ze^2}{4\pi\varepsilon_0 r},$$

where $p_r = -i\hbar\,(\partial/\partial r + 1/r)$ is the operator for the radial momentum and $\mathbf{L} = -i\hbar(\mathbf{r}\times\boldsymbol{\nabla})$ the operator for the orbital angular momentum. The commutation relations between the components of L are $[L_x, L_y] = i\hbar L_z$, $[L_y, L_z] = i\hbar L_x$, $[L_z, L_x] = i\hbar L_y$ and further we have $[L_x, \mathbf{L}^2] = 0$, $[L_y, \mathbf{L}^2] = 0$, $[L_z, \mathbf{L}^2] = 0$. Analogous commutation relations hold for the components of $\mathbf{S}$, the vector operator for the electron spin. $\mathbf{L}$ and $\mathbf{S}$ act in orthogonal sectors of the Hilbert space ($\mathbf{L}$ acts on the position coordinates and $\mathbf{S}$ on the spin coordinates). Give a short explanation in your answers on the following questions. *Note*: vector operators commute if the *components* of the vector operators commute.
Answer the following questions:

   (a) Does H_0 commute with $\mathbf{L}^2$?
   (b) Does H_0 commute with $\mathbf{L}$?
   (c) Does H_0 commute with $\mathbf{S}$?
   (d) Does H_0 commute with $\mathbf{L}\cdot\mathbf{S}$?
   (e) Does H_0 commute with $\mathbf{J} = \mathbf{L} + \mathbf{S}$?
   (f) Does $\mathbf{L}$ commute with $\mathbf{S}$?
   (g) Does $\mathbf{L}$ commute with $\mathbf{L}$?
   (h) Does $\mathbf{L}$ commute with $\mathbf{J}$?
   (i) Does $\mathbf{L}\cdot\mathbf{S}$ commute with $\mathbf{J}$?
   (j) Does $\mathbf{L}\cdot\mathbf{S}$ commute with $\mathbf{L}$?

   Note: Perturbation theory for degenerate levels reduces to ordinary perturbation theory when the perturbation commutes with the unperturbed Hamiltonian. Therefore, we exercise here the commutation relations. Once a commutation rule is proven it can be used for proving or (disproving) subsequent relations.

2. **The Darwin term**: Check the validity of the approximation leading to Eq. 4.19 where the wavefunction $R_{nl}(r)$ gets replaced by its value at the origin $R_{nl}(0)$ using Mathematica. Calculate the ratio of the more exact integral in the equation preceding 4.19 with 4.19 for Hydrogen and $n = 2, l = 0$. Show that in the limit $R \to 0$, the ratio goes to unity. What is the (numerical) ratio when $R = \lambda_c$? (Hint: in atomic units, this corresponds to $\tilde{R} = \alpha$).

The qubits of ^{40}Ca$^+$

1. The spontaneous lifetime τ for the transition $|n'l'm'\rangle \to |nlm\rangle$ from the excited state $|n'l'm'\rangle$ is given (to first order in perturbation theory) by the relation

$$\frac{1}{\tau} = \frac{8\pi^2}{3\hbar\varepsilon_0}\frac{D^2_{n'l'm',nlm}}{\lambda^3},$$

The lifetime of the $3d$ level in atomic hydrogen is 15.6 ns. This decay is limited by electric-dipole transitions and is observed as fluorescence after laser excitation. What is this lifetime for the $3d$ level in Ca$^+$ (to first order in perturbation theory? Why is the $3d$ level in Ca$^+$ called "metastable"?

2. The ^{40}Ca nucleus has nuclear spin $I = 0$. Therefore, the level structure of ^{40}Ca$^+$ is fully defined by its fine structure (*i.e.*, hyperfine structure is absent). Make a sketch of the atomic level diagram of the $4s$, $4p$ and $3d$ levels of ^{40}Ca$^+$, including fine structure and indicate the Zeeman splitting of the $^2S_{1/2}$ and $^2D_{5/2}$ manifolds.

3. Two types of qubits can be encoded in the ^{40}Ca$^+$ ion. Using microwave radiation a qubit can be encoded in the magnetic sublevels of the $^2S_{1/2}$ ground state manifold - this is called the microwave qubit. Using an electric quadrupole transition a qubit can be encoded in two magnetic sublevels, one in the $^2S_{1/2}$ electronic ground state and one in the $^2D_{5/2}$ metastable state - this is called the optical qubit. How would you use a pulsed laser to demonstrate that a single ^{40}Ca$^+$ ion is in the metastable state without affecting the occupation of this state or its entanglement with another qubit?

Q.10 Problem set 5 - solutions

SOLUTIONS PROBLEMS CHAPTER 4

1. **The LSJ commute**: The Schrödinger Hamiltonian can be written as

$$H_0 = \frac{1}{2\mu}\left(p_r^2 + \frac{\mathbf{L}^2}{r^2}\right) - \frac{Ze^2}{4\pi\varepsilon_0 r},$$

where $p_r = -i\hbar\,(\partial/\partial r + 1/r)$ is the operator for the radial momentum and $\mathbf{L} = -i\hbar(\mathbf{r}\times\boldsymbol{\nabla})$ the operator for the orbital angular momentum. The commutation relations between the components of L are $[L_x, L_y] = i\hbar L_z$, $[L_y, L_z] = i\hbar L_x$, $[L_z, L_x] = i\hbar L_y$ and further we have $[L_x, \mathbf{L}^2] = 0$, $[L_y, \mathbf{L}^2] = 0$, $[L_z, \mathbf{L}^2] = 0$. Analogous commutation relations hold for the components of $\mathbf{S}$, the vector operator for the electron spin. $\mathbf{L}$ and $\mathbf{S}$ act in orthogonal sectors of the Hilbert space ($\mathbf{L}$ acts on the position coordinates and $\mathbf{S}$ on the spin coordinates). Give a short explanation in your answers on the following questions. *Note*: vector operators commute if the *components* of the vector operators commute.
Answers to the questions:

   (a) Yes, H_0 commutes with $\mathbf{L}^2$, because $\mathbf{L}^2$ is a scalar operator and all scalar operators commutes with itself. Further $\mathbf{L}^2$ commutes with r and also with p_r because $\mathbf{L}^2$ acts only on the angular variables.

   (b) Yes, H_0 commutes with $\mathbf{L}$, because $\mathbf{L}^2$ commutes with the components of $\mathbf{L}$ (see intro). Further, $\mathbf{L}$ commutes with r because of the reason given under (1a).

   (c) Yes, H_0 commutes with $\mathbf{S}$, because H_0 does not depend on spin.

   (d) Yes, H_0 commutes with $\mathbf{L}\cdot\mathbf{S} = L_xS_x + L_yS_y + L_zS_z$ because H_0 commutes with (the components of) $\mathbf{L}$ and with $\mathbf{S}$.

   (e) Yes, H_0 commutes with $\mathbf{J} = \mathbf{L} + \mathbf{S}$ because H_0 commutes with $\mathbf{L}$ and $\mathbf{S}$.

   (f) Yes, $\mathbf{L}$ commutes with $\mathbf{S}$ because these operators act on different coordinates.

   (g) (0.4) No, $\mathbf{L}$ commutes *not* with $\mathbf{L}$. Scalar operators commutes always with itself. In the case of vector operators the components should satisfy but this is not the case. Counter example: $[L_x, L_y] = i\hbar L_z$.

   (h) No, $\mathbf{L}$ commutes *not* with $\mathbf{J}$ because $\mathbf{J} = \mathbf{L} + \mathbf{S}$ and $\mathbf{L}$ do commute with $\mathbf{S}$ but not with $\mathbf{L}$ - see question (1g).

   (i) Yes, $\mathbf{L}\cdot\mathbf{S}$ commutes with $\mathbf{J}$ because $\mathbf{L}\cdot\mathbf{S} = \frac{1}{2}[\mathbf{J}^2 - \mathbf{L}^2 - \mathbf{S}^2]$ and J_i commutes with $\mathbf{J}^2$, L_i commutes with $\mathbf{L}^2$ and S_i commutes with $\mathbf{S}^2$ (by definition of angular momentum).

   (j) No, $\mathbf{L}\cdot\mathbf{S}$ commutes not with $\mathbf{L}$. Counter example: $[L_x, \mathbf{L}\cdot\mathbf{S}] = [L_x, L_xS_x + L_y derived S_y + L_zS_z] = [L_x, L_x]S_x + [L_x, L_y]S_y + [L_x, L_z]S_z = 0 + i\hbar L_zS_y - i\hbar L_yS_z \neq 0$ - see also question (1g).

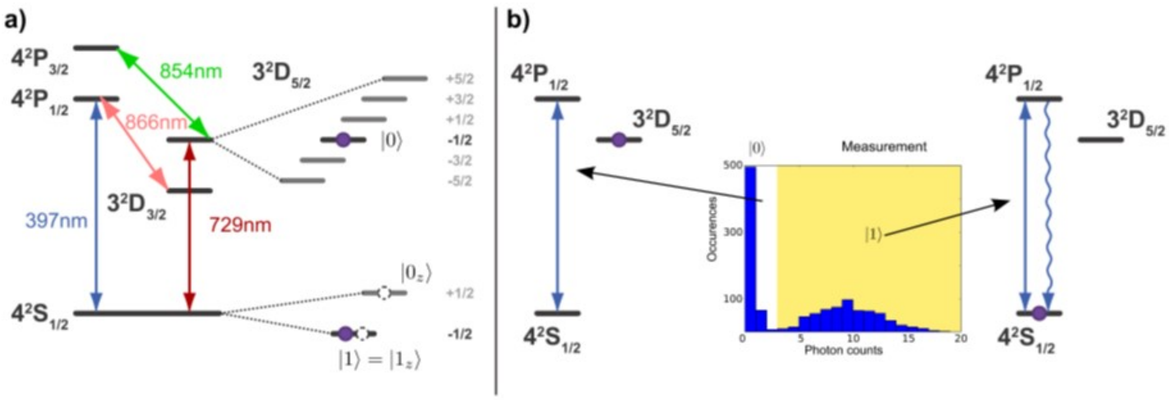
2. *See notebook.* What is the (numerical) ratio when $R = \lambda_c$? - *Answer: the ratio is 0.9945*

The qubits of ^{40}Ca$^+$

1. The spontaneous lifetime τ for the transition $|n'l'm'\rangle \to |nlm\rangle$ from the excited state $|n'l'm'\rangle$ is given by the relation

$$\frac{1}{\tau} = \frac{8\pi^2}{3\hbar\varepsilon_0}\frac{D^2_{n'l'm',nlm}}{\lambda^3},$$

The lifetime of the $3d$ level in atomic hydrogen is 15.6 ns. This decay is limited by electric-dipole transitions and is observed as fluorescence after laser excitation. What is this lifetime for the $3d$ level in Ca$^+$ (to first order in perturbation theory? Why is the $3d$ level in Ca$^+$



Figuur Q.1: (a) Atomic level diagram of ${}^{40}\mathrm{Ca}^+$; (b) demonstration of metastable state.

called "metastable"?
Answer: the electric-dipole lifetime of the $3d$ level is infinite because the p level lies above the d level and $d \to s$ transitions are not dipole allowed because $\Delta l = 2$.

2. The ${}^{40}\mathrm{Ca}$ nucleus has nuclear spin $I = 0$. Therefore, the level structure of ${}^{40}\mathrm{Ca}^+$ is fully defined by its fine structure (*i.e.*, hyperfine structure is absent). Make a sketch of the atomic level diagram of the $4s$, $4p$ and $3d$ levels of ${}^{40}\mathrm{Ca}^+$, including fine structure and indicate the Zeeman splitting of the ${}^2S_{1/2}$ and ${}^2D_{5/2}$ manifolds.
Answer: see Fig. Q.1-a

3. Two types of qubits can be encoded in the ${}^{40}\mathrm{Ca}^+$ ion. Using microwave radiation a qubit can be encoded in the magnetic sublevels of the ${}^2S_{1/2}$ ground state manifold - this is called the microwave qubit. Using an electric quadrupole transition a qubit can be encoded in two magnetic sublevels, one in the ${}^2S_{1/2}$ electronic ground state and one in the ${}^2D_{5/2}$ metastable state - this is called the optical qubit. How would you use a pulsed laser to demonstrate that a single ${}^{40}\mathrm{Ca}^+$ ion is in the metastable state without affecting the occupation of this state or its entanglement with another qubit?
Answer: excitation of the $s \to p$ transition. If the electron is *shelved* in the metastable state no fluorescence is observed during the lifetime of the metastable state (see Fig. Q.1-b).

Q.11 Problem set 6

PROBLEMS CHAPTER 4 (CONTINUED)

Fine structure and Zeeman effect of p states in hydrogenic atoms

Consider the Hamiltonian

$$\mathcal{H} = \mathcal{H}_0 + \mathcal{H}' \qquad \text{with} \qquad \begin{cases} \mathcal{H}_0 = \dfrac{1}{2\mu}\left(p_r^2 + \dfrac{\mathbf{L}^2}{r^2}\right) - \dfrac{Ze^2}{4\pi\varepsilon_0 r} \\ \mathcal{H}' = \mathcal{H}_{LS} + \mathcal{H}_Z, \end{cases}$$

where $\mathcal{H}_{LS} = \xi(r)\mathbf{L}\cdot\mathbf{S}$ is the spin-orbit interaction and $\mathcal{H}_Z = (g_L L_z + g_e S_z)\,\mu_B B/\hbar$ the Zeeman interaction. We approximate $g_L = 1$ and $g_e = 2$. The *spin-orbit coupling strength* is

$$\xi(r) \simeq -\frac{1}{2\mu^2c^2}\frac{e}{r}\frac{d\varphi(r)}{dr}, \tag{Q.7}$$

where $\varphi(r) = Ze/4\pi\varepsilon_0 r$ is the Coulomb potential of the nuclear charge Ze. The Hamiltonian H_0 gives rise to $(2l+1)\,(2s+1)$-fold degenerate energy levels. This degeneracy is lifted by H', a combination of spin-orbit and Zeeman interaction. The splitting can be calculated in the high-field and the low-field limit with the expressions of ordinary perturbation theory for *non-degenerate* levels. Note that all questions lead to Question 9; *hence, pay special attention to Question 9.*

Questions:

1. What condition should hold between H_0 and H' to assure that perturbation theory for degenerate levels reduces to ordinary perturbation theory? Is this condition satisfied for $H' = \mathcal{H}_Z$? Why? Is this condition satisfied for $H' = \mathcal{H}_{LS}$? Why? Explain why we can use first order perturbation theory to calculate the fine structure of hydrogen for levels of given principal quantum number n.

2. Do $\mathcal{H}_{LS}$ and $\mathcal{H}_Z$ commute? The commutation relations between the components of an angular momentum operator $\mathbf{L}$ are $[L_x, L_y] = i\hbar L_z$, $[L_y, L_z] = i\hbar L_x$, $[L_z, L_x] = i\hbar L_y$.

3. One distinguishes between low-field ($\langle\mathcal{H}_Z\rangle \ll \langle\mathcal{H}_{LS}\rangle$) and high-field ($\langle\mathcal{H}_Z\rangle \gg \langle\mathcal{H}_{LS}\rangle$) expressions for the Zeeman shift. Which quantum number(s) is (are) conserved for any value of the magnetic field (such a quantum number is called a "good" quantum number)?

4. In *low* magnetic fields, where $\langle\mathcal{H}_Z\rangle \ll \langle\mathcal{H}_{LS}\rangle$, the orbital and spin angular momenta couple to the total angular momentum $\mathbf{J} = \mathbf{L} + \mathbf{S}$. The matrix elements of L_Z and S_Z in the so-called *coupled basis* $\{|nlsjm_j\rangle\}$ are proportional to the matrix element of J_z. This is expressed by the Wigner-Eckart theorem in the following form:

$$\begin{aligned}\langle nlsjm_j|L_Z|nlsjm_j\rangle &= \langle lsj||L||lsj\rangle\langle jm_j|J_Z|jm_j\rangle \\ \langle nlsjm_j|S_Z|nlsjm_j\rangle &= \langle lsj||S||lsj\rangle\langle jm_j|J_Z|jm_j\rangle,\end{aligned}$$

   where the proportionality factor $\langle lsj||L||lsj\rangle$ and $\langle lsj||S||lsj\rangle$ are projections on the $\mathbf{J}$ vector given by

$$\langle lsj||L||lsj\rangle = \frac{\langle nlsjm_j|\mathbf{L}\cdot\mathbf{J}|nlsjm_j\rangle}{\langle nlsjm_j|\mathbf{J}^2|nlsjm_j\rangle} \quad \text{and} \quad \langle lsj||S||lsj\rangle = \frac{\langle nlsjm_j|\mathbf{S}\cdot\mathbf{J}|nlsjm_j\rangle}{\langle nlsjm_j|\mathbf{J}^2|nlsjm_j\rangle}.$$

   Calculate $\langle lsj||L||lsj\rangle$ and $\langle lsj||S||lsj\rangle$. What is the name of these proportionality factors?

5. Show that in *low* magnetic fields, $\langle\mathcal{H}_Z\rangle \ll \langle\mathcal{H}_{LS}\rangle$, the Zeeman shift can be written as $\Delta E^Z_{n,j}(B) = \langle nlsjm_j|\mathcal{H}'|nlsjm_j\rangle = g_J\mu_B B m_j$ to first order in perturbation theory.

6. What is the name of the g-factor g_J? Give an expression for g_J in terms of l, s and j. Can g_J be negative in hydrogenic atoms?

7. Give an expression for the spin-orbit shift in zero-field in terms of the spin-orbit coupling constant $\zeta_{nl} = \langle nl|\xi(r)|nl\rangle\hbar^2$. Can ζ_{nl} be negative in hydrogenic atoms? Explain your answer. Derive the Landé interval rule for the splitting of the levels ${}^{2s+1}L_J$ and ${}^{2s+1}L_{J-1}$.

8. In *high* magnetic fields, where $\langle\mathcal{H}_Z\rangle \gg \langle\mathcal{H}_{LS}\rangle$, the Zeeman shift is best calculated in the *uncoupled basis* $\{|nlm_l s m_s\rangle\} \equiv \{|nlm_l\rangle \otimes |sm_s\rangle\}$. Give the *high* magnetic field expression for the Zeeman shift $\Delta E^Z_{n,m_l,m_s}(B)$ to first order in perturbation theory and including the spin-orbit contribution.

9. Sketch the fine structure as a function of magnetic field for the case $l = 1, s = 1/2$. Use the spectroscopic Term notation to label the levels in zero magnetic field. *Important:* fill out the following table for the high-field limit

m_l	m_s	m_j	$m_l m_s$	$m_l + 2m_s$

Which quantity is associated with $m_l + 2m_s$?

Q.12 Problem set 6 - solutions

SOLUTIONS PROBLEMS CHAPTER 4 (CONTINUED)

Fine structure and Zeeman effect of p states in hydrogenic atoms

Consider the Hamiltonian

$$\mathcal{H} = \mathcal{H}_0 + \mathcal{H}' \qquad \text{with} \qquad \begin{cases} \mathcal{H}_0 = \dfrac{1}{2\mu}\left(p_r^2 + \dfrac{\mathbf{L}^2}{r^2}\right) - \dfrac{Ze^2}{4\pi\varepsilon_0 r} \\ \mathcal{H}' = \mathcal{H}_{LS} + \mathcal{H}_Z, \end{cases}$$

where $\mathcal{H}_{LS} = \xi(r)\mathbf{L}\cdot\mathbf{S}$ is the spin-orbit interaction and $\mathcal{H}_Z = (g_L L_z + g_e S_z)\,\mu_B B/\hbar$ the Zeeman interaction. We approximate $g_L = 1$ and $g_e = 2$. The *spin-orbit coupling strength* is

$$\xi(r) \simeq -\frac{1}{2\mu^2 c^2}\frac{e}{r}\frac{d\varphi(r)}{dr}, \tag{Q.8}$$

where $\varphi(r) = Ze/4\pi\varepsilon_0 r$ is the Coulomb potential of the nuclear charge Ze. The Hamiltonian H_0 gives rise to $(2l+1)(2s+1)$-fold degenerate energy levels. This degeneracy is lifted by H', a combination of spin-orbit and Zeeman interaction. The splitting can be calculated in the high-field and the low-field limit with the expressions of ordinary perturbation theory for *non-degenerate* levels.

Answers:

1. To assure that perturbation theory for degenerate levels can be reduced to ordinary perturbation theory we require $[H_0, H'] = 0$. This is the case for the Zeeman interaction, $[\mathcal{H}_0, \mathcal{H}_Z] = 0$, because L_z and S_z commute with $\mathbf{L}^2$ as well as with all r dependent terms of $\mathcal{H}_0$. This is not the case for the spin-orbit interaction, $[\mathcal{H}_0, \mathcal{H}_{LS}] \neq 0$, because $\xi(r)$ does *not* commute with $\mathcal{H}_0$ and $\mathcal{H}_r$. However, $[H_0, \mathcal{H}_{LS}] \simeq 0$, more precisely $[H_0, \mathcal{H}_{LS}] = 0$ "*to first order in perturbation theory*". To understand this feature we first note that $[\mathcal{H}_0, \mathbf{L}\cdot\mathbf{S}] = 0$ because: (a) $\mathbf{L}\cdot\mathbf{S}$ commutes with any function of r (since $\mathbf{L}$ and $\mathbf{S}$ are independent of r); (b) $[\mathbf{L}\cdot\mathbf{S}, p_r^2] = 0$ (since spin operates in its own sector of Hilbert space and p_r is independent of θ and ϕ); (c) $[\mathbf{L}^2, \mathbf{L}\cdot\mathbf{S}] = 0$ (since $[\mathbf{L}^2, L_i S_i] = [\mathbf{L}^2, L_i]S_i + L_i[\mathbf{L}^2, S_i] = 0$ for $i \in \{x, y, z\}$). However, $\xi(r)$ does *not* commute with $\mathcal{H}_0$ and $\mathcal{H}_r$ (because r does not commute with p_r). This of no consequence as long as the second order correction remains small. This is the case because the fine-structure splitting is much smaller (factor α^2) than the level separation of the main structure. Therefore, only states within the selected manifold of *given* principal quantum number n enter the calculation in first-order - see Eq. (H.56) and below. Thus, n is a good quantum number but *only to first order in perturbation theory.*

2. $\mathcal{H}_{LS}$ and $\mathcal{H}_Z = (L_z + 2S_z)\,\mu_B B/\hbar$ do *not* commute. To proof this we first note that $\mathbf{L}\cdot\mathbf{S}$ commutes neither with L_z nor with S_z. We show this for L_z (for S_z the proof goes analogously)

$$\begin{aligned}[\mathbf{L}\cdot\mathbf{S}, L_z] &= [L_x S_x + L_y S_y + L_z S_z, L_z] \\ &= [L_x, L_z]S_x + [L_y, L_z]S_y = -i\hbar L_y S_x + i\hbar L_x S_y = i\hbar\,(L_x S_y - L_y S_x) \neq 0.\end{aligned}$$

$$\begin{aligned}[\mathbf{L}\cdot\mathbf{S}, S_z] &= [L_x S_x + L_y S_y + L_z S_z, S_z] \\ &= L_x[S_x, S_z] + L_y[S_y, S_z] = -i\hbar L_x S_y + i\hbar L_y S_x = -i\hbar\,(L_x S_y - L_y S_x) \neq 0.\end{aligned}$$

Hence,

$$[\mathbf{L}\cdot\mathbf{S}, L_z + S_z] = 0.$$

This is a *happy cancellation* of terms. In general the sum of two nonvanishing commutators will be nonvanishing; in particular

$$[\mathbf{L}\cdot\mathbf{S}, L_z + 2S_z] = -i\hbar\,(L_xS_y - L_yS_x) \neq 0.$$

3. One distinguishes between low-field ($\langle\mathcal{H}_Z\rangle \ll \langle\mathcal{H}_{LS}\rangle$) and high-field ($\langle\mathcal{H}_Z\rangle \gg \langle\mathcal{H}_{LS}\rangle$) expressions for the Zeeman shift. Correspondingly we have for the atomic fine structure a low field Hamiltonian $\mathcal{H} = \mathcal{H}_0 + \mathcal{H}_r + \mathcal{H}_{LS}$ with quantum numbers n, l, s, j, m_j and a high field Hamiltonian $\mathcal{H} = \mathcal{H}_0 + \mathcal{H}_r + \mathcal{H}_Z$ with the quantum numbers n, l, m_l, s, m_s. From these quantum numbers n, l, s are quantum numbers in any field (these correspond to joint eigenstates of $\mathcal{H}_0, \mathcal{H}_r, \mathcal{H}_{LS}$ and $\mathcal{H}_Z$). The quantum number j corresponds to the joint eigenstates of $\mathcal{H}_0 + \mathcal{H}_r$ and $\mathcal{H}_{LS}$ but *not* of $\mathcal{H}_Z$. Therefore, j is *not* a good quantum number in arbitrary field (in particular not in high field). Likewise m_l and m_s are (individually) good quantum numbers of $\mathcal{H}_Z$ but *not* of $\mathcal{H}_{LS}$. Therefore, m_l and m_s are (individually) *not* good quantum numbers in arbitrary field (in particular not in low field). The operator J_z commutes with both $\mathcal{H}_{LS}$ and $\mathcal{H}_Z$. Therefore (see Problem F.1), the operator $J_z = L_z + S_z$ shares its eigenstates $|m_j\rangle$ and quantum number $m_j = m_l + m_s$ with the operators $\mathcal{H}_{LS}$ and $\mathcal{H}_Z$. Thus $m_j = m_l + m_s$ is a "good" quantum number (see Appendix F.2.4). Alternatively we can argue that $\mathbf{L}\cdot\mathbf{S} = L_zS_z + \frac{1}{2}[L_+S_- + L_-S_+]$. This means that whenever L_+ raises m_l by 1 the operator S_- will lower m_s by 1 (and vice versa), hence $m_l + m_s$ will be conserved. On the other hand $\mathbf{J}^2 = \mathbf{L}^2 + \mathbf{S}^2 + 2\mathbf{L}\cdot\mathbf{S}$ and L_z, S_z do not commute because $\mathbf{L}\cdot\mathbf{S}$ does not commute with $g_LL_z + g_eS_z$ (*no happy cancellation* - see question 2). Therefore j, m_l and m_s are not good quantum numbers in arbitrary field.

4. In *low* magnetic fields, where $\langle\mathcal{H}_Z\rangle \ll \langle\mathcal{H}_{LS}\rangle$, the orbital and spin angular momenta couple to the total angular momentum $\mathbf{J} = \mathbf{L} + \mathbf{S}$. The matrix elements of L_Z and S_Z in the so-called *coupled basis* $\{|nlsjm_j\rangle\}$ are proportional to the matrix element of J_z. This is expressed by the Wigner-Eckart theorem,

$$\begin{aligned}\langle nlsjm_j|L_Z|nlsjm_j\rangle &= \langle lsj||L||lsj\rangle\langle jm_j|J_Z|jm_j\rangle\\ \langle nlsjm_j|S_Z|nlsjm_j\rangle &= \langle lsj||S||lsj\rangle\langle jm_j|J_Z|jm_j\rangle.\end{aligned}$$

The proportionality factors $\langle lsj||L||lsj\rangle$ and $\langle lsj||S||lsj\rangle$ are given by

$$\begin{aligned}\langle lsj||L||lsj\rangle &= \frac{\langle nlsjm_j|\mathbf{L}\cdot\mathbf{J}|nlsjm_j\rangle}{\langle nlsjm_j|\mathbf{J}^2|nlsjm_j\rangle}\\ &= \frac{\langle nlsjm_j|\mathbf{L}^2 + \mathbf{L}\cdot\mathbf{S}|nlsjm_j\rangle}{\langle nlsjm_j|\mathbf{J}^2|nlsjm_j\rangle}\\ &= \frac{\langle nlsjm_j|\mathbf{J}^2 + \mathbf{L}^2 - \mathbf{S}^2|nlsjm_j\rangle}{2\langle nlsjm_j|\mathbf{J}^2|nlsjm_j\rangle}\\ &= \frac{j(j+1) + l(l+1) - s(s+1)}{2j(j+1)}.\end{aligned}$$

Likewise we derive

$$\langle lsj||S||lsj\rangle = \frac{j(j+1) - l(l+1) + s(s+1)}{2j(j+1)}.$$

These proportionality factors are called *reduced matrix elements.*

5. In *low* magnetic fields, where $\langle \mathcal{H}_Z \rangle \ll \langle \mathcal{H}_{LS} \rangle$, the Zeeman shift is given by

$$\begin{aligned}\Delta E^Z_{n,j}(B) &= \langle nlsjm_j|\mathcal{H}'|nlsjm_j\rangle \\ &= \left[\langle lsj||L||lsj\rangle + 2\langle lsj||S||lsj\rangle\right]\mu_B B/\hbar\langle jm_j|J_Z|jm_j\rangle \\ &= \left[\langle lsj||L||lsj\rangle + 2\langle lsj||S||lsj\rangle\right]\mu_B B m_j \\ &= g_J \mu_B B m_j,\end{aligned}$$

where the g-factor is defined by

$$g_J = \langle lsj||L||lsj\rangle + 2\langle lsj||S||lsj\rangle.$$

6. (1.0) The g-factor g_J is called the Landé g-factor.

$$\begin{aligned}g_J &= \langle lsj||L||lsj\rangle + 2\langle lsj||S||lsj\rangle \\ &= \frac{j(j+1)+l(l+1)-s(s+1)}{2j(j+1)} + \frac{2j(j+1)-2l(l+1)+2s(s+1)}{2j(j+1)} \\ &= \frac{2j(j+1)+j(j+1)-l(l+1)+s(s+1)}{2j(j+1)} \\ &= 1 + \frac{j(j+1)-l(l+1)+s(s+1)}{2j(j+1)}\end{aligned}$$

For hydrogen-like atoms we have $s = 1/2$ and the Landé factor reduces to the compact form

$$g_J = 1 \pm \frac{1}{2l+1} \qquad \text{for } j = l \pm 1/2 \text{ with } l \neq 0 \text{ and } s = 1/2.$$

For $l = 0$ we have $g_J = 2$. Since $l \geq 0$ the g factor is always *positive* ($g_J > 0$) and largest for the state with the largest multiplicity (highest j).

7. The spin-orbit shift is given by

$$\begin{aligned}\Delta E^{LS}_{n,j} &= \frac{1}{2}\langle nl|\,\xi(r)\,|nl\rangle\,\langle lsjm_j|\,\mathbf{J}^2 - \mathbf{L}^2 - \mathbf{S}^2\,|lsjm_j\rangle \\ &= \frac{1}{2}\langle nl|\,\xi(r)\,|nl\rangle\,\hbar^2\left[j(j+1)-l(l+1)-s(s+1)\right] \\ &= \frac{1}{2}\zeta_{nl}\left[j(j+1)-l(l+1)-s(s+1)\right].\end{aligned}$$

The coupling constant ζ_{nl} can not be negative in hydrogenic atoms because

$$\xi(r) \simeq \frac{1}{2\mu^2c^2}\frac{1}{r}\frac{d}{dr}\frac{-Ze^2}{4\pi\varepsilon_0 r} = \frac{1}{2\mu^2c^2}\frac{Ze^2}{4\pi\varepsilon_0 r^3} > 0.$$

The Landé interval rule for the spin-orbit splitting of two subsequent spin-orbit levels ${}^{2s+1}L_J$ and ${}^{2s+1}L_{J-1}$ is

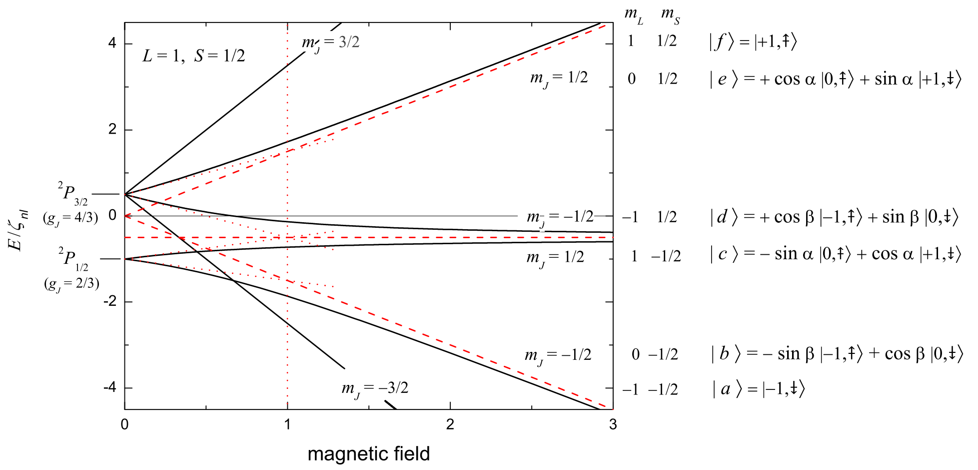
$$\Delta W = \Delta E^{LS}_{n,j} - \Delta E^{LS}_{n,j-1} = \zeta_{nl} j.$$

8. (1.0) In *high* magnetic fields, where $\langle \mathcal{H}_Z \rangle \gg \langle \mathcal{H}_{LS} \rangle$, the Zeeman shift dominates and is given by

$$\begin{aligned}\Delta E^Z_{n,m_l,m_s}(B) &= \langle nlm_l sm_s|\mathcal{H}_Z + \mathcal{H}_{LS}|nlm_l sm_s\rangle \\ &= \langle lm_l sm_s|L_z + 2S_z|lm_l sm_s\rangle \mu_B B/\hbar \\ &\quad + \left(\zeta_{nl}/\hbar^2\right)\langle lm_l sm_s|L_zS_z + \tfrac{1}{2}[L_+S_- + L_-S_+]|lm_l sm_s\rangle.\end{aligned}$$

Since the high-field limit is a case of weak coupling, we may neglect the off-diagonal terms to lowest order in perturbation theory (see Appendix G.3.4) and obtain

$$\begin{aligned}\Delta E^Z_{n,m_l,m_s}(B) &= \langle lm_l sm_s|L_z + 2S_z|lm_l sm_s\rangle \mu_B B/\hbar \\ &\qquad + \left(\zeta_{nl}/\hbar^2\right)\langle lm_l sm_s|L_z S_z|lm_l sm_s\rangle \\ &= \mu_B B\,(m_l + 2m_s) + \zeta_{nl} m_l m_s\end{aligned}$$



9. The fine structure versus magnetic field is sketched above for the case $l = 1, s = \frac{1}{2}$. The high-field limit is analyzed in the table below.

m_l	m_s	m_j	$m_l m_s$ (ζ_{nl})	$m_l + 2m_s$ ($\mu_B B$)
1	$\frac{1}{2}$	$\frac{3}{2}$	$\frac{1}{2}$	2
1	$-\frac{1}{2}$	$\frac{1}{2}$	$-\frac{1}{2}$	0
0	$\frac{1}{2}$	$\frac{1}{2}$	0	1
0	$-\frac{1}{2}$	$-\frac{1}{2}$	0	-1
-1	$\frac{1}{2}$	$-\frac{1}{2}$	$-\frac{1}{2}$	0
-1	$-\frac{1}{2}$	$-\frac{3}{2}$	$\frac{1}{2}$	-2

Note that $(m_l + 2m_s)\,\mu_B B$ is the effective magnetic moment in the high field limit.

Q.13 Problem set 7

PROBLEMS CHAPTER 5

Ground-state hyperfine structure of hydrogen-like atoms

1. Consider the Hamiltonian for the ground state $\left(1^2S_{1/2}\right)$ of hydrogenic atoms

$$\mathcal{H} = \mathcal{H}_0 + \mathcal{H}' \qquad \text{with} \qquad \begin{cases} \mathcal{H}_0 = \dfrac{1}{2\mu}\left(p_r^2 + \dfrac{\mathbf{L}^2}{r^2}\right) - \dfrac{Ze^2}{4\pi\varepsilon_0 r} \\ \\ \mathcal{H}' = \left(a_{\text{hfs}}/\hbar^2\right)\mathbf{I}\cdot\mathbf{S} + (g_e\mu_B S_z - g_I\mu_N I_z)B/\hbar \end{cases} .$$

where $g_e = 2$ is the g-factor of the electron

$$a_{\text{hfs}}\left(n\,^{2s+1}L_J\right) = \frac{\mu_0}{4\pi}\frac{2}{3}\frac{g_s\mu_B\gamma_I\hbar}{[(1+m_e/M)a_0]^3}\left[R_{n0}(0)\right]^2$$

is the hyperfine coupling constant of the Fermi contact interaction. The low field g-factor is

$$g_F = \pm g_J\frac{1}{2I+1} \quad \text{for } F = I \pm 1/2$$

where

$$g_J = 1 + \frac{[j(j+1) + s(s+1) - l(l+1)]}{2j(j+1)}.$$

is the *Landé factor.*

(a) Give an expression for the zero-field hyperfine shift ΔE_F^{IS} in terms of the quantum numbers I, S and F using the so-called coupled basis of $\mathbf{I}$ and $\mathbf{S}$, valid to first order in ordinary perturbation theory.

(b) Why is it allowed to use ordinary perturbation theory in the so-called coupled basis $\{|sIFm_F\rangle\}$ to calculate the lifting of degeneracy of degenerate F levels in zero field?

(c) Write the matrix elements for the Zeeman effect including the hyperfine interaction in the high-field basis $\{|sm_sIm_I\rangle\}$. Which terms are diagonal and which are off-diagonal? Why is it allowed to use ordinary perturbation theory to lift the degeneracy of degenerate F levels in the high field limit if the off-diagonal terms may be neglected?

(d) Why is $m_F = m_s + m_I$ in all fields a "good" quantum number of the full Hamiltonian?

(e) Give an expression (in terms of the quantum numbers m_s and m_I) for the Zeeman effect for magnetic fields $B \gg a_{\text{hfs}}/\mu_B$.

(f) Sketch the hyperfine diagram as a function of magnetic field and indicate the m_F value of all levels for atoms with ($l = 0$, $S = 1/2$, $I = 1$) for

   a. positive gyromagnetic ratio ($\gamma_I > 0$)
   b. negative gyromagnetic ratio ($\gamma_I < 0$)

Q.14 Problem set 7 - solutions

SOLUTIONS PROBLEMS CHAPTER 5

Ground-state hyperfine structure of hydrogen-like atoms

1. Consider the Hamiltonian for the ground state $\left(1^2S_{1/2}\right)$ of hydrogenic atoms

$$\mathcal{H} = \mathcal{H}_0 + \mathcal{H}' \qquad \text{with} \qquad \begin{cases} \mathcal{H}_0 = \dfrac{1}{2\mu}\left(p_r^2 + \dfrac{\mathbf{L}^2}{r^2}\right) - \dfrac{Ze^2}{4\pi\varepsilon_0 r} \\ \\ \mathcal{H}' = \left(a_{\mathrm{hfs}}/\hbar^2\right)\mathbf{I}\cdot\mathbf{S} + (g_e\mu_B S_z - g_I\mu_N I_z)B/\hbar \end{cases} .$$

where $g_e = 2$ is the g-factor of the electron

$$a_{\mathrm{hfs}}\left(n\,^{2s+1}L_J\right) = \frac{\mu_0}{4\pi}\frac{2}{3}\frac{g_s\mu_B\gamma_I\hbar}{[(1+m_e/M)a_0]^3}\left[R_{n0}(0)\right]^2$$

is the hyperfine coupling constant of the Fermi contact interaction. The low field g-factor is

$$g_F = \pm g_J\frac{1}{2I+1} \quad \text{for } F = I \pm 1/2$$

where

$$g_J = 1 + \frac{[j(j+1) + s(s+1) - l(l+1)]}{2j(j+1)}.$$

is the *Landé factor*.

(a) The zero-field hyperfine shift is given by

$$\begin{aligned} \Delta E_F^{IS} &= \left(a_{\mathrm{hfs}}/\hbar^2\right)\langle sIFm_F|\mathbf{I}\cdot\mathbf{S}|sIFm_F\rangle \\ &= \frac{1}{2}a_{\mathrm{hfs}}\{\langle sIFm_F|\mathbf{F}^2 - \mathbf{I}^2 - \mathbf{S}^2|sIFm_F\rangle\} \\ &= \frac{1}{2}a_{\mathrm{hfs}}\{F(F+1) - I(I+1) - s(s+1)\}. \end{aligned}$$

(b) The above expression holds for ordinary first-order perturbation theory in the so called coupled basis $\{|sIFm_F\rangle\}$ (in which $\mathbf{I}$ and s are coupled into $\mathbf{F}$ by the $\mathbf{I}\cdot\mathbf{S}$ term). This is allowed because both $\mathbf{I}^2$, $\mathbf{S}^2$, $\mathbf{F}^2$ and F_z commute with the Hamiltonian:

(c) In the high-field basis $\{|sm_sIm_I\rangle\}$ the matrix elements for the Zeeman effect, including the hyperfine interaction, are given by

$$\begin{aligned} \Delta E_Z = \langle sm_s'Im_I'|\left(a_{\mathrm{hfs}}/\hbar^2\right)I_zS_z + (g_e\mu_B S_z - g_I\mu_N I_z)B/\hbar|sm_sIm_I\rangle \\ + \tfrac{1}{2}\left(a_{\mathrm{hfs}}/\hbar^2\right)\langle sm_s'Im_I'|I_+S_- + I_-S_+|sm_sIm_I\rangle \end{aligned}$$

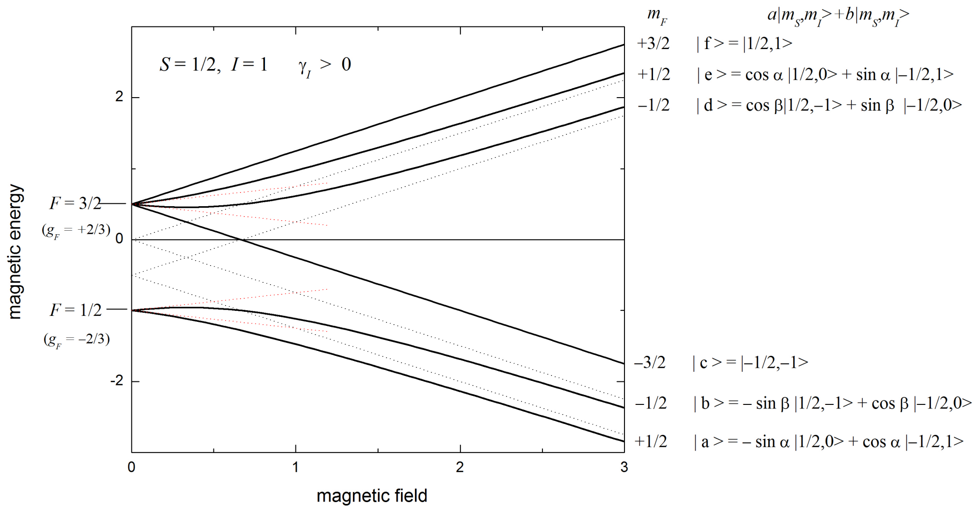
The diagonal terms are $\langle sm_sIm_I|\left(a_{\mathrm{hfs}}/\hbar^2\right)I_zS_z + (g_e\mu_B S_z - g_I\mu_N I_z)B/\hbar|sm_sIm_I\rangle$ and the off-diagonal terms are $\frac{1}{2}\left(a_{\mathrm{hfs}}/\hbar^2\right)\langle sm_s'Im_I'|I_+S_- + I_-S_+|sm_sIm_I\rangle$. If the off-diagonal terms may be neglected H' commutes with H_0. Thus, we may use ordinary perturbation theory to calculate the Zeeman shift.

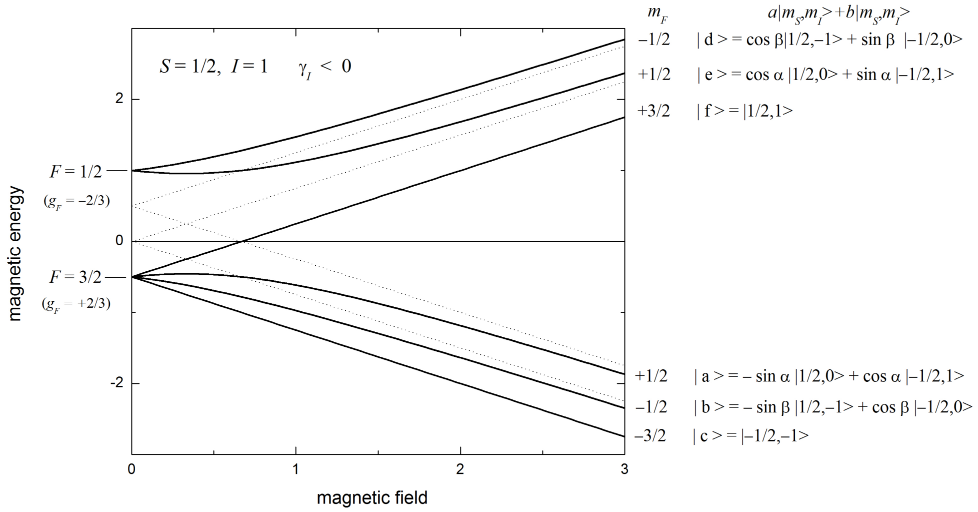
(d) The value $m_F = m_s + m_I$ is a "good" quantum number of the full Hamiltonian $\mathcal{H}$ in all fields because F_z commutes with $\mathcal{H}$:
$[F_z, \mathbf{I}\cdot\mathbf{S}] = \frac{1}{2}\{[F_z, \mathbf{F}^2] - [F_z, \mathbf{I}^2] - [F_z, \mathbf{S}^2]\} = 0$ since $[I_z + S_z, \mathbf{I}^2] = 0$ and $[I_z + S_z, \mathbf{S}^2] = 0$.
Furthermore, F_z also commutes with $\mathcal{H}_0$ and $\mathcal{H}_r$ because these are independent of spin.

(e) The expression (in terms of the quantum numbers m_s and m_I) for the Zeeman effect in high magnetic fields ($B \gg a_{\mathrm{hfs}}/\mu_B$) is:

$$\Delta E_Z = a_{\mathrm{hfs}} m_s m_I + (g_e \mu_B m_s - g_I \mu_N m_I) B/\hbar$$

(f) The requested hyperfine diagrams are given below:





Q.15 Problem set 8

PROBLEMS CHAPTER 7

Helium-like atoms

1. Consider an atom or ion of nuclear charge Ze and two electrons in the $1s^2$ configuration. Analyze this system using first-order perturbation theory and Hartree atomic units.
   (a) Give an expression for the energy shift $\Delta\varepsilon_{\mathrm{scr}}$ caused by the electrostatic repulsion between the two electrons.

   (b) Express $\Delta\varepsilon_{\mathrm{scr}}^{(1)}$ in terms of the angular and radial integrals
   (c) Find the value of the angular integral in Table 7.1.
   (d) Give an expression for the radial integral in Dirac notation.
   (e) Give an expression for the screening potential $U_F^0(\rho)$ of the $1s$ hydrogenic wavefunction, $\tilde{R}_{1s}(\rho) = Z^{3/2}2e^{-Z\rho}$. *Hint:* use symbolic integration (*e.g.*, with Mathematica).
   (f) Give an expression for the radial integral $F^0(1s;1s)$ of the $1s$ hydrogenic wavefunction. *Hint:* use symbolic integration.
   (g) Give an expression for the screening shift of the $1s$ hydrogenic wavefunction.
   (h) Give an expression for the ground state energy of the system.
   (i) Calculate the ground state energy for ^{4}He, H$^-$ and Be^{2+}.
   (j) Calculate the binding energy of the second electron for ^{4}He, H$^-$ and Be^{2+}.
   (k) Do your results for the binding energy of ^{4}He and H$^-$ agree with the values given in the syllabus?
   (l) The negative ion of hydrogen is stable. Give arguments for the existence of the stable negative ion of hydrogen.
   (m) Show that (in Hartree atomic units) the effective electrostatic scalar potential of a $1s$ electron in the Coulomb field of a nucleus of charge Ze is given by

   $$\tilde{\phi}_{\mathrm{eff}}(\rho) = (1/\rho)\left[(Z-1) + (1+Z\rho)e^{-2Z\rho}\right].$$

   This potential is called a screened Coulomb potential.

2. Derive the expansion

   $$\frac{1}{(\rho_1^2+\rho_2^2-2\rho_1\rho_2\cos\theta_{12})^{1/2}} = \frac{1}{\rho_>}\sum_{k=0}^{\infty}\left(\frac{\rho_<}{\rho_>}\right)^k P_k(\cos\theta_{12})$$

   at least to power $k=2$ in powers of the ratio $(\rho_</\rho_>)$, where $\rho_< = \min\{\rho_1,\rho_2\}$ is the lesser and $\rho_> = \max\{\rho_1,\rho_2\}$ the greater of ρ_1 and ρ_2.

3. Show that $a^k(lm_l;l'm_{l'}) = 0$ for $k = $ odd

4. Derive the expression for the exchange coefficient $b^k(lm_l;l'm_{l'})$,

   $$\begin{aligned} b^k(lm_l;l'm_{l'}) &= \frac{4\pi}{2k+1}\sum_{m=-k}^{k}\langle l'm_{l'}|Y_k^{m*}(\hat{\mathbf{r}}_1)|lm_l\rangle\langle lm_l|Y_k^m(\hat{\mathbf{r}}_2)|l'm_{l'}\rangle \\ &= (2l+1)(2l'+1)\begin{pmatrix} l & k & l' \\ 0 & 0 & 0\end{pmatrix}^2\begin{pmatrix} l & k & l' \\ -m_l & (m_l-m_{l'}) & m_{l'}\end{pmatrix}^2. \end{aligned}$$

Q.16 Problem set 8 - solutions

SOLUTIONS PROBLEMS CHAPTER 7

Helium-like atoms

1. Consider an atom or ion of nuclear charge Ze and two electrons in the $1s^2$ configuration. Analyze this system using first-order perturbation theory and Hartree atomic units.

   (a) Give an expression for the energy shift $\Delta\varepsilon_{\rm scr}$ caused by the electrostatic repulsion between the two electrons.
   Answer: $\Delta\varepsilon_{\rm scr} \simeq \langle 1s,1s|\mathcal{H}'|1s,1s\rangle = \mathcal{J}$, where $\mathcal{H}' = 1/\rho_{12}$.

   (b) Express $\Delta\varepsilon^{(1)}_{\rm scr}$ in terms of the angular and radial integrals
   Answer: $\Delta\varepsilon^{(1)}_{\rm scr} = a^0(00;00)F^0(1s;1s)$.

   (c) Find the value of the angular integral in table 7.1.
   Answer: $a^0(00;00) = 1$.

   (d) Give an expression for the radial integral in Dirac notation.
   Answer: $F^0(1s;1s) = \langle 1s|U^0_F(\rho)|1s\rangle$.

   (e) (0.75) Give an expression for the screening potential $U^0_F(\rho)$ of the $1s$ hydrogenic wavefunction, $\tilde{R}_{1s}(\rho) = Z^{3/2}2e^{-Z\rho}$. *Hint:* use symbolic integration.
   Answer:

$$U^0_F(\rho) = \frac{1}{\rho}\int_0^\rho \left[\tilde{R}_{1s}(x)\right]^2 x^2dx + \int_\rho^\infty \frac{1}{x}\left[\tilde{R}_{1s}(x)\right]^2 x^2dx = \frac{1}{\rho}\left[1-e^{-2Z\rho}(1+Z\rho)\right].$$

   (f) Give an expression for the radial integral $F^0(1s;1s)$ of the $1s$ hydrogenic wavefunction. *Hint:* use symbolic integration.
   Answer:

$$F^0(1s;1s) = Z^3 4\int_a^\infty \left[1-e^{-2Z\rho}(1+Z\rho)\right]e^{-2Z\rho}\rho d\rho = \tfrac{5}{8}Z.$$

   (g) Give an expression for the screening shift of the $1s$ hydrogenic wavefunction.
   Answer: The screening shift is given by

$$\Delta\varepsilon^{(1)}_{\rm scr} = +\tfrac{5}{8}Z.$$

   (h) Give an expression for the ground state energy of the system.
   Answer: The ground state of the system is given by

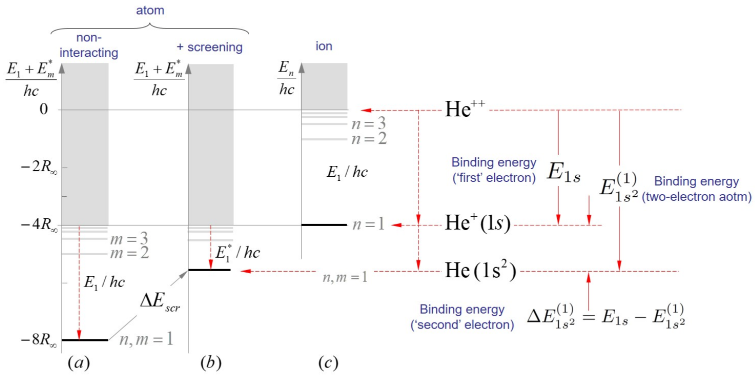
$$E^{(1)}_{1s^2} = -Z^2 + \tfrac{5}{8}Z.$$

   (i) Calculate the ground state energy for ^{4}He, H$^-$ and Be^{2+}.
   Answer: The ground state energies in Hartree atomic units are: ^{4}He: $-4+5/4=-11/4$; H$^-$: $-1+5/8=-3/8$; Be^{2+}: $-16+5/2=-27/2$.

   (j) Calculate the binding energy of the second electron. *Answer:* The expression for the binding energy of the second electron is (see Fig. Q.1)

$$\Delta E^{(1)}_{1s^2} = -\left(E^{(1)}_{1s^2} - E_{1s}\right) = -\tfrac{1}{2}Z^2 + Z^2 - \tfrac{5}{8}Z = \tfrac{1}{2}Z^2 - \tfrac{5}{8}Z.$$

   With this expression we calculate for the binding energy (in Hartree atomic units): ^{4}He: 3/4, H$^-$: $-1/8$ (not bound) and Be^{2+}: 11/2.



Figuur Q.1

(k) Do your results for the binding energy of ^{4}He and H$^-$ agree with the values given in the syllabus?
Answer: Yes, the values agree.

(l) The negative ion of hydrogen is stable. Give arguments for the existence of the stable negative ion of hydrogen.
Answer: To achieve binding the calculation has to account for the presence of correlations because these tend to increase the average distance between the electrons. This obviously lowers the electrostatic repulsion and, therefore increases the binding energy.

(m) Show that (in Hartree atomic units) the effective electrostatic scalar potential of a $1s$ electron in the Coulomb field of a nucleus of charge Ze is given by

$$\varphi_{\text{eff}}(\rho) = (1/\rho)\left[(Z-1) + (1+Z\rho)e^{-2Z\rho}\right].$$

This potential is called a screened Coulomb potential.
Answer: Adding the potential energy of the electron in the Coulomb field of the nucleus, $-Z/\rho$, to the potential energy of screening (the "screening potential" derived in question 1e), $U_F^0(\rho)$, we obtain

$$U_{\text{CF}}(\rho) = -(1/\rho)\left[(Z-1) + (1+Z\rho)e^{-2Z\rho}\right].$$

This is the effective central-field potential of a $1s$ electron in the Coulomb field of a nucleus of charge Ze. To obtain the effective *electrostatic scalar potential* (screened Coulomb potential) we have to divide by the electron charge, $-e$. In atomic units this results in the expression given above for $\varphi_{\text{eff}}(\rho)$.

2. First we define the quantities $x = \dfrac{\rho_<}{\rho_>}$ and $y = x^2 - 2x\cos\theta_{12}$. Then, we do the expansion

$$\begin{aligned}\mathcal{H}'(\rho_{12}) &= \frac{1}{\rho_{12}} = \frac{1}{(\rho_1^2 + \rho_2^2 - 2\rho_1\rho_2\cos\theta_{12})^{1/2}} \\ &= \frac{1}{\rho_>}\frac{1}{(1 + x^2 - 2x\cos\theta_{12})^{1/2}} \\ &= \frac{1}{\rho_>}\frac{1}{(1+y)^{1/2}}\end{aligned}$$

$$(1+y)^\alpha = 1 + \binom{\alpha}{1}y + \binom{\alpha}{2}y^2 + \cdots = 1 + \alpha y + \frac{\alpha(\alpha-1)}{2}y^2 + \cdots$$

For $\alpha = -1/2$ this becomes when substituting $y = x^2 - 2x\cos\theta_{12}$

$$\begin{aligned}
(1+y)^{-1/2} &= 1 - \frac{1}{2}y + \frac{3}{8}y^2 + \cdots \\
&= 1 - \frac{1}{2}\left(x^2 - 2x\cos\theta_{12}\right) + \frac{3}{8}\left(x^2 - 2x\cos\theta_{12}\right)^2 + \cdots \\
&= 1 + x\cos\theta_{12} - \frac{1}{2}x^2 + \frac{3}{8}4x^2\cos^2\theta_{12} + \cdots \\
&= 1 + x\cos\theta_{12} + x^2\frac{1}{2}(3\cos^2\theta_{12} - 1) + \cdots \\
&= P_0\left(\cos\theta_{12}\right) + xP_1\left(\cos\theta_{12}\right) + x^2P_2\left(\cos\theta_{12}\right) + \cdots \\
&= \sum_{k=0}^{\infty} x^k P_k\left(\cos\theta_{12}\right).
\end{aligned}$$

Thus, with $x = \dfrac{\rho_<}{\rho_>}$ we arrive at

$$\mathcal{H}'(\rho_{12}) = \frac{1}{\rho_{12}} = \sum_{k=0}^{\infty}\left(\frac{\rho_<}{\rho_>}\right)^k \frac{P_k\left(\cos\theta_{12}\right)}{\rho_>}.$$

3. $a^k(lm_l; l'm_{l'}) = 0$ for $k =$ odd because

$$a^k(lm_l; l'm_{l'}) = (-1)^{m_l+m_{l'}}(2l+1)(2l'+1)\begin{pmatrix} l & k & l \\ 0 & 0 & 0\end{pmatrix}\begin{pmatrix} l & k & l \\ -m_l & 0 & m_l\end{pmatrix}\begin{pmatrix} l' & k & l' \\ 0 & 0 & 0\end{pmatrix}\begin{pmatrix} l' & k & l' \\ -m_{l'} & 0 & m_{l'}\end{pmatrix}$$

and $\begin{pmatrix} l & k & l \\ 0 & 0 & 0\end{pmatrix} = 0$ for $k + 2l =$ odd $\Leftrightarrow k =$ odd (because $\begin{pmatrix} j_1 & j_2 & j_3 \\ 0 & 0 & 0\end{pmatrix} = 0$ for $j_1 + j_2 + j_3 =$ odd).

4. Derive the expression for the exchange coefficient $b^k(lm_l; l'm_{l'})$,

$$\begin{aligned}
b^k(lm_l; l'm_{l'}) &= \frac{4\pi}{2k+1}\sum_{m=-k}^{k}\langle l'm_{l'}|Y_k^{m*}(\hat{\mathbf{r}}_1)|lm_l\rangle\langle lm_l|Y_k^m(\hat{\mathbf{r}}_2)|l'm_{l'}\rangle \\
&= (2l+1)(2l'+1)\begin{pmatrix} l & k & l' \\ 0 & 0 & 0\end{pmatrix}^2\begin{pmatrix} l & k & l' \\ -m_l & (m_l - m_{l'}) & m_{l'}\end{pmatrix}^2.
\end{aligned}$$

The integral over three spherical harmonics results in

$$\begin{aligned}
\int Y_l^{m_l*}(\hat{\mathbf{r}})Y_k^m(\hat{\mathbf{r}})Y_{l'}^{m_{l'}}(\hat{\mathbf{r}})d\hat{\mathbf{r}} &= (-1)^{m_l}\sqrt{\frac{(2l+1)(2k+1)(2l'+1)}{4\pi}}\begin{pmatrix} l & k & l' \\ 0 & 0 & 0\end{pmatrix}\begin{pmatrix} l & k & l' \\ -m_l & m & m_{l'}\end{pmatrix} \\
\int Y_{l'}^{m_{l'}*}(\hat{\mathbf{r}})Y_k^{m*}(\hat{\mathbf{r}})Y_l^{m_l}(\hat{\mathbf{r}})d\hat{\mathbf{r}} &= (-1)^{m_{l'}+m}\sqrt{\frac{(2l+1)(2k+1)(2l'+1)}{4\pi}}\begin{pmatrix} l' & k & l \\ 0 & 0 & 0\end{pmatrix}\begin{pmatrix} l' & k & l \\ -m_{l'} & -m & m_l\end{pmatrix} \\
&= (-1)^{m_{l'}+m}\sqrt{\frac{(2l+1)(2k+1)(2l'+1)}{4\pi}}\begin{pmatrix} l & k & l' \\ 0 & 0 & 0\end{pmatrix}\begin{pmatrix} l & k & l' \\ m_l & -m & -m_{l'}\end{pmatrix}.
\end{aligned}$$

Multiplying these two expressions we find

$$\begin{aligned}\frac{4\pi}{2k+1}\langle l' m_{l'}|Y_k^{m*}(\hat{\mathbf{r}}_1)|l m_l\rangle\langle l m_l|Y_k^{m}(\hat{\mathbf{r}}_2)|l' m_{l'}\rangle =& \\ &= (2l+1)(2l'+1)\begin{pmatrix} l\,k\,l' \\ 0\,0\,0\end{pmatrix}^2\begin{pmatrix} l & k & l' \\ -m_l & m & m_{l'}\end{pmatrix}\begin{pmatrix} l & k & l' \\ m_l & -m & -m_{l'}\end{pmatrix} \\ &= (-1)^{l+l'+k}(2l+1)(2l'+1)\begin{pmatrix} l\,k\,l' \\ 0\,0\,0\end{pmatrix}^2\begin{pmatrix} l & k & l' \\ -m_l & m & m_{l'}\end{pmatrix}^2\end{aligned}$$

which is only non-zero for $|l-l'| \leq k \leq l+l'$, $l+k+l' =$ even *and* $m = m_l - m_{l'}$ because $\begin{pmatrix} j_1 & j_2 & j_3 \\ m_1 & m_2 & m_3\end{pmatrix} = 0$ unless $|j_1 - j_2| \leq j_2 \leq j_1 + j_2$ and $m_1 + m_2 + m_3 = 0$ and because $\begin{pmatrix} j_1\,j_2\,j_3 \\ 0\;\;0\;\;0\end{pmatrix} = 0$ unless $l+k+l' =$ even, further $(-1)^{m_l+m_{l'}+m} = (-1)^{2m_l} = 1$ (because m_l is integer) and $(-1)^{l+k+l'} = 1$ (because $l+k+l' =$ even) (see Appendix J).

Q.17 Problem set 9

Problems Chapter 9

Angular momentum of Slater determinants and Hund's rules

The ground states of the elements of the periodic system can be predicted with the three Hund rules:

1. The *Coulomb repulsion* between the valence electrons of an atomic ground state configuration is *minimal for the maximum (Pauli-allowed) value of the total spin*, S.

2. The *Coulomb repulsion* between the valence electrons of an atomic ground state configuration (of maximal Pauli-allowed S) is *minimal for the maximal (Pauli-allowed) value of the total orbital angular momentum*, L.

3. The *most negative spin-orbit shift* is obtained for the valence electrons of an atomic ground state configuration (of maximal Pauli-allowed S and L) if the *total electronic angular momentum*, J, *is (a) minimal for less-than-half-filled shells*; *(b) maximal for more-than-half-filled shells.* (N.B. Without spin-orbit interaction, states of different J value are degenerate.

Questions:

1. (2.0) Calculate the total orbital angular momentum of the Slater determinant $|\dot{1},\dot{0}\rangle_{np^2}$. Is your result consistent with Hund's rule 2? Is state $|\dot{1},\dot{0}\rangle_{np^2}$ consistent with Hund's rule 1 and 3?

2. (4.0) Calculate the total orbital angular momentum of the Slater determinant $|\dot{2},\dot{1}\rangle_{nd^2}$. Is your result consistent with Hund's rule 2? Is state $|\dot{2},\dot{1}\rangle_{nd^2}$ consistent with Hund's rule 1 and 3?

3. (4.0) Calculate the total orbital angular momentum of the Slater determinant $|\dot{1},\dot{0},-\dot{1}\rangle_{np^3}$. Is your result consistent with Hund's rule 2? Is state $|\dot{1},\dot{0},-\dot{1}\rangle_{np^3}$ consistent with Hund's rule 1 and 3?

Hints: Use Eq. (9.98):

$$\begin{aligned}\mathbf{L}^2|\psi_\alpha\rangle &= \left\{\sum_{\kappa=1}^{N} l^\kappa(l^\kappa+1) + \sum_{\kappa,\kappa'=1}^{N}{}' m_l^\kappa m_l^{\kappa'}\right\}\hbar^2\,|\psi_\alpha\rangle \\ &+ \sum_{\kappa,\kappa'=1}^{N}{}' \sqrt{l^\kappa(l^\kappa+1)-m_l^\kappa(m_l^\kappa+1)}\sqrt{l^{\kappa'}(l^{\kappa'}+1)-m_l^{\kappa'}(m_l^{\kappa'}-1)}\,\hbar^2\,|\psi_\alpha(m_l^\kappa+1)(m_l^{\kappa'}-1)\rangle.\end{aligned}$$

Clarification of notation:

$$|\psi_\gamma\rangle = |\psi_\alpha(m_l^\kappa+1)(m_l^{\kappa'}-1)\rangle \equiv |\psi_\alpha(m_l^{\kappa'}-1)(m_l^\kappa+1)\rangle, \tag{Q.9}$$

with $\kappa,\kappa'\in\{1,\cdots N\}$, indicates that the state $|\alpha_\kappa\rangle = |n^\kappa l^\kappa m_l^\kappa s m_s^\kappa\rangle$ has been replaced by $|\alpha'_\kappa\rangle = |n^\kappa l^\kappa(m_l^\kappa+1)sm_s^\kappa\rangle$ and the state $|\alpha_{\kappa'}\rangle = |n^{\kappa'} l^{\kappa'} m_l^{\kappa'} s m_s^{\kappa'}\rangle$ by $|\alpha'_{\kappa'}\rangle = |n^{\kappa'} l^{\kappa'}(m_l^{\kappa'}-1)sm_s^{\kappa'}\rangle$. Note that

$$|\psi_\alpha(m_l^\kappa+1)(m_l^{\kappa'}-1)\rangle = -|\psi_\alpha\rangle \quad \text{for} \quad m_l^{\kappa'}-m_l^\kappa = 1. \tag{Q.10}$$

Example:

Let us clarify the notation $|\psi_\alpha(m_l^\kappa+1)(m_l^{\kappa'}-1)\rangle$. For the state

$$|\psi_\alpha\rangle = |\alpha_\kappa, \alpha_{\kappa'}\rangle = |\dot{1}, \dot{0}\rangle_{np^2} \tag{Q.11}$$

we have $|\alpha_\kappa\rangle = |n^\kappa l^\kappa m_l^\kappa s m_s^\kappa\rangle = |n, 1, 1, \frac{1}{2}, \frac{1}{2}\rangle$ and $|\alpha_{\kappa'}\rangle = |n^{\kappa'} l^{\kappa'} m_l^{\kappa'} s m_s^{\kappa\prime}\rangle = |n, 1, 0, \frac{1}{2}, \frac{1}{2}\rangle$. The states

$$|\psi_\gamma\rangle = |\psi_\alpha(m_l^\kappa+1)(m_l^{\kappa'}-1)\rangle = |\alpha'_\kappa, \alpha'_{\kappa'}\rangle = |\dot{2}, -\dot{1}\rangle_{np^2} \tag{Q.12a}$$

$$|\psi'_\gamma\rangle = |\psi_\alpha(m_l^\kappa-1)(m_l^{\kappa'}+1)\rangle = |\alpha'_\kappa, \alpha'_{\kappa'}\rangle = |\dot{0}, \dot{1}\rangle_{np^2} = -|\dot{1}, \dot{0}\rangle_{np^2} \tag{Q.12b}$$

correspond to, respectively

$$\left.\begin{aligned} |\alpha'_\kappa\rangle &= |n^\kappa l^\kappa (m_l^\kappa+1) s m_s^\kappa\rangle = |n, 1, 2, \tfrac{1}{2}, \tfrac{1}{2}\rangle \\ |\alpha'_{\kappa'}\rangle &= |n^{\kappa'} l^{\kappa'} (m_l^{\kappa'}-1) s m_s^{\kappa\prime}\rangle = |n, 1, -1, \tfrac{1}{2}, \tfrac{1}{2}\rangle \end{aligned}\right\} \tag{Q.13a}$$

$$\left.\begin{aligned} |\alpha'_\kappa\rangle &= |n^\kappa l^\kappa (m_l^\kappa-1) s m_s^\kappa\rangle = |n, 1, 0, \tfrac{1}{2}, \tfrac{1}{2}\rangle \\ |\alpha'_{\kappa'}\rangle &= |n^{\kappa'} l^{\kappa'} (m_l^{\kappa'}+1) s m_s^{\kappa\prime}\rangle = |n, 1, +1, \tfrac{1}{2}, \tfrac{1}{2}\rangle \end{aligned}\right\}. \tag{Q.13b}$$

Q.18 Problem set 9 - solutions

SOLUTIONS PROBLEMS CHAPTER 9

Angular momentum of Slater determinants and Hund's rules

The ground states of the elements of the periodic system can be predicted with the three Hund rules:

1. The *Coulomb repulsion* between the valence electrons of an atomic ground state configuration is *minimal for the maximum (Pauli-allowed) value of the total spin*, S.
2. The *Coulomb repulsion* between the valence electrons of an atomic ground state configuration (of maximal Pauli-allowed S) is *minimal for the maximal (Pauli-allowed) value of the total orbital angular momentum*, L.
3. The *most negative spin-orbit shift* is obtained for the valence electrons of an atomic ground state configuration (of maximal Pauli-allowed S and L) if the *total electronic angular momentum*, J, *is (a) minimal for less-than-half-filled shells*; *(b) maximal for more-than-half-filled shells.* (N.B. Without spin-orbit interaction, states of different J value are degenerate.)

The total orbital momentum can be calculated using the relation Eq. (9.98):

$$\begin{aligned}\mathbf{L}^2|\psi_\alpha\rangle &= \left\{\sum_{\kappa=1}^{N} l^\kappa(l^\kappa+1) + \sum_{\kappa,\kappa'=1}^{N}{}' m_l^\kappa m_l^{\kappa'}\right\}\hbar^2\,|\psi_\alpha\rangle \\ &+ \sum_{\kappa,\kappa'=1}^{N}{}' \sqrt{l^\kappa(l^\kappa+1) - m_l^\kappa(m_l^\kappa+1)}\sqrt{l^{\kappa'}(l^{\kappa'}+1) - m_l^{\kappa'}(m_l^{\kappa'}-1)}\,\hbar^2\,|\psi_\alpha(m_l^\kappa+1)(m_l^{\kappa'}-1)\rangle.\end{aligned}$$

Questions:

1. (2.0) Calculate the total orbital angular momentum of the Slater determinant $|\dot{1},\dot{0}\rangle_{np^2}$. Is your result consistent with Hund's rule 2? Is state $|\dot{1},\dot{0}\rangle_{np^2}$ consistent with the Hund rules 1 and 3?
Answer:
For two equivalent electrons we have $N=2$ and the expression for $\mathbf{L}^2$ becomes

$$\begin{aligned}\mathbf{L}^2|\dot{1},\dot{0}\rangle_{np^2} &= \left\{2l(l+1) + 2m_l^{(1)}m_l^{(2)}\right\}\hbar^2\,|\dot{1},\dot{0}\rangle_{np^2} \\ &+ \sqrt{l(l+1) - m_l^{(1)}(m_l^{(1)}+1)}\sqrt{l(l+1) - m_l^{(2)}(m_l^{(2)}-1)}\,\hbar^2\,|\psi_\alpha(m_l^{(1)}+1)(m_l^{(2)}-1)\rangle \\ &+ \sqrt{l(l+1) - m_l^{(2)}(m_l^{(2)}+1)}\sqrt{l(l+1) - m_l^{(1)}(m_l^{(1)}-1)}\,\hbar^2\,|\psi_\alpha(m_l^{(2)}+1)(m_l^{(1)}-1)\rangle\end{aligned}$$

Substituting $l^{(1)}=l^{(2)}=l=1$, $m_l^{(1)}=1$ and $m_l^{(2)}=0$ we calculate $m_l^{(1)}m_l^{(2)}=0$ and find - for the notation see Eq. (9.99) and the Example given on the Problem sheet -

$$\begin{array}{lll} m_l^{(1)}(m_l^{(1)}+1)=2 & m_l^{(2)}(m_l^{(2)}-1)=0 & |\psi_\alpha(m_l^{(1)}+1)(m_l^{(2)}-1)\rangle = |\dot{2},-\dot{1}\rangle_{np^2} \\ m_l^{(2)}(m_l^{(2)}+1)=0 & m_l^{(1)}(m_l^{(1)}-1)=0 & |\psi_\alpha(m_l^{(2)}+1)(m_l^{(1)}-1)\rangle = |\dot{0},\dot{1}\rangle_{np^2} = -|\dot{1},\dot{0}\rangle_{np^2}. \end{array}$$

Thus we obtain

$$\mathbf{L}^2|\dot{1},\dot{0}\rangle_{np^2} = \{2l(l+1)-2\}\hbar^2\,|\dot{1},\dot{0}\rangle_{np^2} = 2\hbar^2\,|\dot{1},\dot{0}\rangle_{np^2}$$

and with $L(L+1)=2$ we calculate $L=1$.

According to the three Hund rules the ground state of a np^2 configuration is the LS term ${}^3P_0$; i.e., $L = S = 1$ and $J = 0$. Hence, $L = 1$ is consistent with Hund's rule 2. Note that $M_S = 1$, which implies $S = 1$ and is consistent with Hund's rule 1. Note that $M_J = M_L + M_S = 2$, which implies $M_J > J$ and shows that $|\dot{1},\dot{0}\rangle_{np^2}$ is *not* consistent with Hund's rule 3 (*cf.* Table 10.5). Note that all three Hund's rules can be satisfied for the state $|\bar{1},\bar{0}\rangle_{np^2}$. Furthermore, note that $|\dot{1},\dot{0}\rangle_{np^2}$ and $|\bar{1},\bar{0}\rangle_{np^2}$ must be degenerate as long as we neglect spin-orbit coupling.

2. (4.0) Calculate the total orbital angular momentum of the Slater determinant $|\dot{2},\dot{1}\rangle_{nd^2}$. Is your result consistent with Hund's rule 2? Is state $|\dot{2},\dot{1}\rangle_{nd^2}$ consistent with the Hund rules 1 and 3?

Answer:

For two equivalent electrons we have $N = 2$ and the expression for $\mathbf{L}^2$ becomes

$$\begin{aligned}\mathbf{L}^2|\dot{2},\dot{1}\rangle_{nd^2} &= \left\{2l(l+1) + 2m_l^{(1)}m_l^{(2)}\right\}\hbar^2\,|\dot{2},\dot{1}\rangle_{nd^2}\\ &+ \sqrt{l(l+1)-m_l^{(1)}(m_l^{(1)}+1)}\sqrt{l(l+1)-m_l^{(2)}(m_l^{(2)}-1)}\,\hbar^2\,|\psi_\alpha(m_l^{(1)}+1)(m_l^{(2)}-1)\rangle_{nd^2}\\ &+ \sqrt{l(l+1)-m_l^{(2)}(m_l^{(2)}+1)}\sqrt{l(l+1)-m_l^{(1)}(m_l^{(1)}-1)}\,\hbar^2\,|\psi_\alpha(m_l^{(2)}+1)(m_l^{(1)}-1)\rangle_{nd^2}\end{aligned}$$

Substituting $l^{(1)} = l^{(2)} = l = 2$, $m_l^{(1)} = 2$ and $m_l^{(2)} = 1$ we calculate $m_l^{(1)}m_l^{(2)} = 2$ and

$$\begin{array}{lll} m_l^{(1)}(m_l^{(1)}+1) = 6 & m_l^{(2)}(m_l^{(2)}-1) = 0 & |\psi_\alpha(m_l^{(1)}+1)(m_l^{(2)}-1)\rangle = |\dot{3},\dot{0}\rangle_{np^2}\\ m_l^{(2)}(m_l^{(2)}+1) = 2 & m_l^{(1)}(m_l^{(1)}-1) = 2 & |\psi_\alpha(m_l^{(2)}+1)(m_l^{(1)}-1)\rangle = -|\dot{2},\dot{1}\rangle_{np^2}\end{array}$$

Thus we obtain

$$\mathbf{L}^2|\dot{2},\dot{1}\rangle_{nd^2} = \{2l(l+1)+4\}\,\hbar^2\,|\dot{2},\dot{1}\rangle_{nd^2} - 4\,\hbar^2\,|\dot{2},\dot{1}\rangle_{np^2} = 12\hbar^2\,|\dot{2},\dot{1}\rangle_{nd^2}$$

and with $L(L+1) = 12$ we calculate $L = 3$.

According to the three Hund rules the ground state of a nd^2 configuration is the LS term ${}^3F_2$; i.e., $L = 3$, $S = 1$ and $J = 2$. Hence, $L = 3$ is consistent with Hund's rule 2. Note that $M_S = 1$, which implies $S = 1$ and is consistent with Hund's rule 1. Note that $M_J = M_L + M_S = 4$, which implies $M_J > J$ and shows that $|\dot{2},\dot{1}\rangle_{nd^2}$ is *not* consistent with Hund's rule 3. Note that all three Hund's rules can be satisfied for the state $|\bar{2},\bar{1}\rangle_{nd^2}$. Furthermore, note that $|\dot{2},\dot{1}\rangle_{nd^2}$ and $|\bar{2},\bar{1}\rangle_{nd^2}$ must be degenerate as long as we neglect spin-orbit coupling.

3. (4.0) Calculate the total orbital angular momentum of the Slater determinant $|\dot{1},\dot{0},-\dot{1}\rangle_{np^3}$. Is your result consistent with Hund's rule 2? Is state $|\dot{1},\dot{0},-\dot{1}\rangle_{np^3}$ consistent with the Hund rules 1 and 3?

Answer:

For three equivalent electrons we have $N=3$ the expression for $\mathbf{L}^2$ becomes

$$\begin{aligned}
\mathbf{L}^2|\dot{1},\dot{0},-\dot{1}\rangle_{np^3} &= \left\{3l(l+1)+2\left(m_l^{(1)}m_l^{(2)}+m_l^{(2)}m_l^{(3)}+m_l^{(1)}m_l^{(3)}\right)\right\}\hbar^2\,|\dot{1},\dot{0},-\dot{1}\rangle_{np^3}\\
&+\sqrt{l(l+1)-m_l^{(1)}(m_l^{(1)}+1)}\sqrt{l(l+1)-m_l^{(2)}(m_l^{(2)}-1)}\,\hbar^2\,|\psi_\alpha(m_l^{(1)}+1)(m_l^{(2)}-1)\rangle_{np^3}\\
&+\sqrt{l(l+1)-m_l^{(2)}(m_l^{(2)}+1)}\sqrt{l(l+1)-m_l^{(1)}(m_l^{(1)}-1)}\,\hbar^2\,|\psi_\alpha(m_l^{(2)}+1)(m_l^{(1)}-1)\rangle_{np^3}\\
&+\sqrt{l(l+1)-m_l^{(2)}(m_l^{(2)}+1)}\sqrt{l(l+1)-m_l^{(3)}(m_l^{(3)}-1)}\,\hbar^2\,|\psi_\alpha(m_l^{(2)}+1)(m_l^{(3)}-1)\rangle_{np^3}\\
&+\sqrt{l(l+1)-m_l^{(3)}(m_l^{(3)}+1)}\sqrt{l(l+1)-m_l^{(2)}(m_l^{(2)}-1)}\,\hbar^2\,|\psi_\alpha(m_l^{(3)}+1)(m_l^{(2)}-1)\rangle_{np^3}\\
&+\sqrt{l(l+1)-m_l^{(1)}(m_l^{(1)}+1)}\sqrt{l(l+1)-m_l^{(3)}(m_l^{(3)}-1)}\,\hbar^2\,|\psi_\alpha(m_l^{(1)}+1)(m_l^{(3)}-1)\rangle_{np^3}\\
&+\sqrt{l(l+1)-m_l^{(3)}(m_l^{(3)}+1)}\sqrt{l(l+1)-m_l^{(1)}(m_l^{(1)}-1)}\,\hbar^2\,|\psi_\alpha(m_l^{(3)}+1)(m_l^{(1)}-1)\rangle_{np^3}.
\end{aligned}$$

Substituting $l^{(1)}=l^{(2)}=l=1$, $m_l^{(1)}=1$, $m_l^{(2)}=0$ and $m_l^{(3)}=-1$ we calculate

$$\begin{aligned}
m_l^{(1)}m_l^{(2)} &= m_l^{(2)}m_l^{(3)} = 0\\
m_l^{(1)}m_l^{(3)} &= -1
\end{aligned}$$

and

$$\begin{array}{lll}
m_l^{(1)}(m_l^{(1)}+1)=2 & m_l^{(2)}(m_l^{(2)}-1)=0 & |\psi_\alpha(m_l^{(1)}+1)(m_l^{(2)}-1)\rangle = |\dot{2},-\dot{1},-\dot{1}\rangle_{np^3}\to 0\\
m_l^{(2)}(m_l^{(2)}+1)=0 & m_l^{(1)}(m_l^{(1)}-1)=0 & |\psi_\alpha(m_l^{(2)}+1)(m_l^{(1)}-1)\rangle = -|\dot{1},\dot{0},-\dot{1}\rangle_{np^3}\\
m_l^{(2)}(m_l^{(2)}+1)=0 & m_l^{(3)}(m_l^{(3)}-1)=2 & |\psi_\alpha(m_l^{(2)}+1)(m_l^{(3)}-1)\rangle = |1,1,-2\rangle_{np^3}\to 0\\
m_l^{(3)}(m_l^{(3)}+1)=0 & m_l^{(2)}(m_l^{(2)}-1)=0 & |\psi_\alpha(m_l^{(3)}+1)(m_l^{(2)}-1)\rangle = -|1,0,-1\rangle_{np^3}\\
m_l^{(1)}(m_l^{(1)}+1)=2 & m_l^{(3)}(m_l^{(3)}-1)=-2 & |\psi_\alpha(m_l^{(1)}+1)(m_l^{(3)}-1)\rangle = |2,0,-2\rangle_{np^3}\\
m_l^{(3)}(m_l^{(3)}+1)=0 & m_l^{(1)}(m_l^{(1)}-1)=0 & |\psi_\alpha(m_l^{(3)}+1)(m_l^{(1)}-1)\rangle = |0,0,0\rangle_{np^3}\to 0.
\end{array}$$

Note that $|\dot{2},-\dot{1},-\dot{1}\rangle_{np^3}=0$, $|\dot{1},\dot{1},-\dot{2}\rangle_{np^3}=0$ and $|\dot{0},\dot{0},\dot{0}\rangle_{np^3}=0$ because the determinant are zero (two or more equal columns). Thus we obtain

$$\mathbf{L}^2|\dot{1},\dot{0},-\dot{1}\rangle_{np^3} = \{3l(l+1)-2\}\hbar^2\,|\dot{1},\dot{0},-\dot{1}\rangle_{np^3} - 4\hbar^2\,|\dot{1},\dot{0},-\dot{1}\rangle_{np^3} = 0\hbar^2\,|\dot{1},\dot{0},-\dot{1}\rangle_{np^3}$$

and with $L(L+1)=0$ we calculate $L=0$.

According to the three Hund rules the ground state of a np^3 configuration is the LS term ${}^4S_{3/2}$; i.e., $L=0$, $S=3/2$ and $J=3/2$. Hence, $L=0$ is consistent with Hund's rule 2. Note that $M_S=3/2$, which implies $S=3/2$ and is consistent with Hund's rule 1. Furthermore, we calculate $M_J=M_L+M_S=3/2$, which is automatically consistent with Hund's rule 3 because the np^3 configuration corresponds to a half-filled shell; i.e., $J=S$ and spin-orbit coupling is absent.

Q.19 Problem set 10

PROBLEMS CHAPTER 10

Equivalent electrons, Hund rules and ground state

1. (0.5) Give the definition of equivalent electrons within an atom?
2. (0.5) What is meant by a filled or half-filled electron shell within an atom?
3. (1.0) Consider an electron in the rotational state $|lm\rangle$. What is the probability per unit solid angle to observe this electron in the direction $\hat{\mathbf{r}}$.
4. (1.0) Show explicitly for $l = 1$ and 2 that the charge distributions of closed and half-filled electronic shells are spherically symmetric.
5. (1.0) The nitrogen atom (N) has atomic number $Z = 7$. What is the electron configuration of the ground state of atomic nitrogen?
6. (1.0) Which LS-terms are allowed for atoms with three *non-equivalent* p electrons and further only filled shells?
7. (2.0) Which LS-terms are allowed for three valence electrons in *equivalent* p orbitals?
8. (1.0) For which of the terms determined under (7) do you expect the smallest electrostatic repulsion (and, hence the strongest exchange binding)? Explain your answer.
9. (1.0) Give the three Hund rules: Is the term found under (8) consistent with the first Hund rule?
10. (1.0) Do you need the second and/or third Hund rule to determine the ground state or is this state already identified by applying the first Hund rule?

Q.20 Problem set 10 - solutions

SOLUTIONS PROBLEMS CHAPTER 10

Equivalent electrons, Hund rules and ground state

1. (0.5) Equivalent electrons are electrons sharing the same quantum numbers n and l.
2. (0.5) A half-filled shell is a set of $2l+1$ equivalent electrons with the same spin occupying all spinorbitals with $-l \leq m_l \leq l$; a closed shell is a set of $2\,(2l+1)$ equivalent electrons with all possible spinorbitals with $-l \leq m_l \leq l$ doubly occupied with a spin-up and a spin-down electron.
3. (1.0) The probability per unit solid angle to find an electron in the direction $\hat{\mathbf{r}}$ is given by $|Y_l^m(\hat{\mathbf{r}})|^2$.
4. (1.0) For a half-filled shell of p electrons we have for the sum of probabilities to find the electron in the direction $\hat{\mathbf{r}}$

$$\sum_{m=-1}^{1} |Y_1^m(\hat{\mathbf{r}})|^2 = Y_1^0(\hat{\mathbf{r}}) + 2|Y_1^1(\hat{\mathbf{r}})|^2 = \frac{3}{4\pi}\left(\cos^2\theta + \sin^2\theta\right) = \frac{3}{4\pi}.$$

As this result in independent of $\hat{\mathbf{r}}$ the distribution is spherically symmetric. Likewise, we have for a half-filled shell of d electrons

$$\begin{aligned}\sum_{m=-2}^{2} |Y_2^m(\hat{\mathbf{r}})|^2 &= |Y_2^0(\hat{\mathbf{r}})|^2 + 2|Y_2^1(\hat{\mathbf{r}})|^2 + 2|Y_2^2(\hat{\mathbf{r}})|^2 \\ &= \frac{5}{4\pi}\left[\frac{1}{4}\left(3\cos^2\theta - 1\right)^2 + 3\sin^2\theta\cos^2\theta + \frac{3}{4}\sin^4\theta\right] \\ &= \frac{5}{4\pi}\left[\frac{3}{4}\left(3\cos^4\theta - 2\cos^2\theta + \frac{1}{3}\right) + \frac{3}{4}4\sin^2\theta\cos^2\theta + \frac{3}{4}\sin^4\theta\right] \\ &= \frac{5}{4\pi}\left[\frac{3}{4}\left(2\cos^4\theta - 2\cos^2\theta + 2\sin^2\theta\cos^2\theta\right) + \frac{1}{4} + \frac{3}{4}\left(\cos^4\theta + 2\sin^2\theta\cos^2\theta + \sin^4\theta\right)\right] \\ &= \frac{5}{4\pi}\left[\frac{3}{4}\left(2\cos^2\theta\{\cos^2\theta + \sin^2\theta\} - 2\cos^2\theta\right) + 1\right] = \frac{5}{4\pi}.\end{aligned}$$

For fully filled shells the probabilities double but remain independent of $\hat{\mathbf{r}}$.

5. (1.0) The ground state configuration of atomic nitrogen is $1s^2 2s^2 2p^3$.
6. (1.0) Three *non-equivalent* p electrons (and further only closed shells) correspond to an angular momentum Hilbert space of dimension $(2s+1)^3(2l+1)^3 = 6^3 = 216$ as determined in the *uncoupled* representation. Adding the orbital angular momenta of two p electrons we find three possibilities $l_{12} = 0, 1, 2$. Each of these possiblities has to be combined with the third p electron: $(l_{12}, l) = (0, 1)$ results in $L = 1$; $(l_{12}, l) = (1, 1) \rightarrow L = 0, 1, 2$; $(l_{12}, l) = (2, 1) \rightarrow L = 1, 2, 3$. So we identified the following possibilities for the total orbital angular momentum: $L = 0, 1(3\times), 2(2\times), 3$. Next we turn to the spin part and find with the same approach for the total spin $S = 1/2(2\times), 3/2$. We now have to couple L and S: For $S = 1/2(2\times)$ we find

$$(L,S) = \begin{cases} (0,1/2) \rightarrow J = 1/2 & {}^2S_{1/2} : (1 \times 2\times) : deg = 4 \\ (1,1/2) \rightarrow J = 1/2, 3/2 & {}^2P_{1/2,3/2} : (3 \times 2\times) : deg = 36 \\ (2,1/2) \rightarrow J = 3/2, 5/2 & {}^2D_{3/2,5/2} : (2 \times 2\times) : deg = 40 \\ (3,1/2) \rightarrow J = 5/2, 7/2 & {}^2F_{5/2,7/2} : (1 \times 2\times) : deg = 28 \end{cases}$$

So, in total, we found 108 degenerate doublet states. For $S = 3/2$ we find

$$(L,S) = \begin{cases} (0,3/2) \to J = 3/2 & {}^4S_{3/2} : (1 \times 1\times) : deg = 4 \\ (1,3/2) \to J = 1/2, 3/2, 5/2 & {}^4P_{1/2,\cdots,5/2} : (3 \times 1\times) : deg = 36 \\ (2,3/2) \to J = 1/2, 3/2, 5/2, 7/2 & {}^4D_{1/2,\cdots 7/2} : (2 \times 1\times) : deg = 40 \\ (3,3/2) \to J = 3/2, 5/2, 7/2, 9/2 & {}^4F_{3/2,\cdots 9/2} : (1 \times 1\times) : deg = 28 \end{cases}$$

This corresponds to 108 degenerate quartet states (together also a basis of 216 states in the *coupled* representation).

7. (2.0) Three valence electrons in *equivalent* p orbitals yield the LS terms ${}^4S_{3/2}$, ${}^2D_{5/2,3/2}$, ${}^2P_{3/2,1/2}$,

M_S	M_L	Slater determinants	non-zero Slater det′s	$LS-$Terms		
			#		accept.	excl.
3/2	3	$\upharpoonleft\upharpoonleft\upharpoonleft - -$	0	${}^4F$	–	${}^4F$
3/2	2	$\upharpoonleft\upharpoonleft \upharpoonleft -$	0	${}^4D$	–	${}^4D$
3/2	1	$\upharpoonleft \upharpoonleft\upharpoonleft -$	0	${}^4P$	–	${}^4P$
3/2	0	$\upharpoonleft \upharpoonleft \upharpoonleft$	1	${}^4S$	${}^4S$	–
1/2	3	$\upharpoonleft\upharpoonleft\downharpoonright - -$	0	${}^2F$	–	${}^2F$
1/2	2	$\upharpoonleft\downharpoonright \upharpoonleft -$	1	${}^2D$	${}^2D$	–
1/2	1	$\upharpoonleft \upharpoonleft\downharpoonright -, \upharpoonleft\downharpoonright - \upharpoonleft$	2	${}^2D, {}^2P$	${}^2P$	–
1/2	0	$\downharpoonright \upharpoonleft \upharpoonleft, \upharpoonleft \downharpoonright \upharpoonleft, \upharpoonleft \upharpoonleft \downharpoonright$	3	${}^4S, {}^2D, {}^2P, {}^2S$	–	${}^2S$

8. (1.0) From the Terms determined under (7) ${}^4S_{3/2}$ has the smallest electrostatic repulsion between the electrons because the spins are parallel and the electrons cannot approach each other closely. In the case of the ${}^2D_{5/2,3/2}$, ${}^2P_{3/2,1/2}$ terms this restriction is absent. Hence, the ${}^4S_{3/2}$-term corresponds to the largest binding energy.

9. (1.0) The three Hund rules are: (a) maximize S in accordance with the Pauli principle; (b) maximize L in accordance with the Pauli principle; (c) Choose $J = J_{\min} = |L - S|$ for less than half-filled shells and $J = J_{\max} = L + S$ for more than half-filled shells. The state determined under (8) is consistent with the first Hund's rule (maximize S in accordance with the Pauli principle).

10. (1.0) The second and/or third Hund's rule need not be used because we found a single Term ${}^4S_{3/2}$ so that the values of S, L and J are uniquely determined.

2. (3.0) The element *selenium* (Se) is an atom with a regular ground-state configuration.
   (a) (0.2) What is the electron configuration of Se?
   Answer: Se is an element from the 4^{th} period of the Mendeleev table. It has a (regular) ground-state electron configuration: $[\mathrm{Ar}]3d^{10}4s^2 4p^4$.
   (b) (0.3) Use the Hund rules to determine the LS ground state term of Se.
   Answer: All three Hund rules are used to determine the ground state
      i. Choose first the maximum value of S consistent with the Pauli principle: $S = 1$.

ii. Choose then the maximum value of L consistent with the Pauli principle: $L = 1$.
iii. Choose next $J = J_{\max} = L + S$ for shells *more* than half-filled: the LS term is ${}^3P_2$.

(c) (0.5) Name all LS terms possible for four *non-equivalent* p electrons (Note that for more than two electrons LS terms may appear more than once!).
Answer: We investigate the electron configuration [Zn]$4p^4$. Four non-equivalent p electrons (and further only closed shells) correspond to an angular momentum Hilbert space of dimension $(2s+1)^4(2l+1)^4 = 6^4 = 1296$. Combining the orbital angular momenta vectorially yields for the total orbital angular momentum the possible values $L = 0\,(3\times)$, $1\,(6\times)$, $2\,(6\times)$, $3\,(3\times)$, $4\,(1\times)$ and for the total spin $S = 0\,(2\times)$, $1\,(3\times)$, $2\,(1\times)$. This corresponds to 162 LS terms of the *singlet* type, 729 *triplets* and 405 *quintets*, together again 1296 states (the latter is a valuable check sum but not essential for solving the problem),

p^4		L					degeneracy
coupled		0	1	2	3	4	1296
S	0	${}^1\mathrm{S}_0$	${}^1\mathrm{P}_1$	${}^1\mathrm{D}_2$	${}^1\mathrm{F}_3$	${}^1\mathrm{G}_4$	162
	1	${}^3\mathrm{S}_1$	${}^3\mathrm{P}_{0,1,2}$	${}^3\mathrm{D}_{1,2,3}$	${}^3\mathrm{F}_{2,3,4}$	${}^3\mathrm{G}_{3,4,5}$	729
	2	${}^5\mathrm{S}_2$	${}^5\mathrm{P}_{1,2,3}$	${}^5\mathrm{D}_{0,1,2,3,4}$	${}^5\mathrm{F}_{1,2,3,4,5}$	${}^5\mathrm{G}_{2,3,4,5,6}$	405

(d) (0.5) Determine all LS terms possible for four *equivalent* p electrons consistent with the Pauli principle.
Answer B: We can make a decision table for four equivalent p electrons. In this approach we search for

$$\binom{6}{4} = \frac{6!}{4!2!} = \frac{6\times 5}{2} = 15$$

nonzero terms:

M_S	M_L	Slater determinants		LS terms			degeneracy
			Pauli allowed:	options	accepted	excl.	15
2	4	↿↿↿↿ − −	0	^{5}G	-	^{5}G	
	3	↿↿↿ ↿ −	0	^{5}F	-	^{5}F	
	2	↿↿ ↿↿ −	0	^{5}D	-	^{5}D	
	1	↿ ↿↿↿ −, ↿↿ ↿ ↿	0	^{5}P	-	^{5}P	
	0	↿↿ − ↿↿, − ↿↿↿↿ −, ↿ ↿↿ ↿	0	^{5}S	-	^{3}S	
1	4	↿⇂↿↿ − −	0	^{3}G	-	^{3}G	
	3	↿↿↿ ⇂ −, ↿⇂↿ ↿ −	0	^{3}F	-	^{3}F	
	2	↿↿ ↿⇂ −, ↿⇂ ↿↿ −, ↿⇂↿ ⇂ (2×)	0	^{3}D	-	^{3}D	
	1	↿⇂ ↿ ↿, ↿ ↿↿⇂ −	1	^{3}P	^{3}P	-	9
	0	↿ ↿⇂ ↿, − ↿↿↿⇂ −	1	^{3}P,^{3}S	-	^{3}S	
0	4	↿⇂↿⇂ − −	0	^{1}G	-	^{1}G	
	3	↿⇂↿ ⇂ − (2×)	0	^{1}F	-	^{1}F	
	2	↿⇂ ↿⇂ −, ↿⇂↿ − ⇂ (2×)	1	^{1}D	^{1}D	-	5
	1	↿⇂ ↿ ⇂ (2×), ↿ ↿⇂⇂ − (2×)	2	^{3}P,^{1}D,^{1}P	-	^{1}P	
	0	↿ ↿⇂ ⇂ (2×), ↿⇂ − ↿⇂, − ↿⇂↿⇂ −	3	^{3}P,^{1}D,^{1}S	^{1}S	-	1

The corresponding Slater determinants are:

np^4 uncoupled		M_S 1	0	-1
M_L	2		$\lvert\dot{1},\bar{1},\dot{0},\bar{0}\rangle$	
	1	$\lvert\dot{1},\bar{1},\dot{0},-\dot{1}\rangle$	$\lvert\dot{1},\bar{1},\bar{0},-\dot{1}\rangle\lvert\dot{1},\bar{1},\dot{0},-\bar{1}\rangle$	$\lvert\dot{1},\bar{1},\bar{0},-\bar{1}\rangle$
	0	$\lvert\dot{1},\dot{0},\bar{0},-\dot{1}\rangle$	$\lvert\dot{1},\dot{0},\bar{0},-\bar{1}\rangle\lvert\dot{1},\bar{1},-\dot{1},-\bar{1}\rangle\lvert\bar{1},\dot{0},\bar{0},-\dot{1}\rangle$	$\lvert\bar{1},\dot{0},\bar{0},-\bar{1}\rangle$
	-1	$\lvert\dot{1},\dot{0},-\dot{1},-\bar{1}\rangle$	$\lvert\dot{1},\bar{0},-\dot{1},-\bar{1}\rangle\lvert\bar{1},\dot{0},-\dot{1},-\bar{1}\rangle$	$\lvert\bar{1},\bar{0},-\dot{1},-\bar{1}\rangle$
	-2		$\lvert\dot{0},\bar{0},-1,-\bar{1}\rangle$	

Or, equivalently,

$\lvert^{2S+1}L;M_L,M_S\rangle$ uncoupled		M_S 1	0	-1
M_L	2		$\lvert^1D;2,0\rangle$	
	1	$\lvert^3P;1,1\rangle$	$\lvert^3P;1,0\rangle\lvert^1D;1,0\rangle$	$\lvert^3P;1,-1\rangle$
	0	$\lvert^3P;0,1\rangle$	$\lvert^3P;0,0\rangle\lvert^1S;0,0\rangle\lvert^1D;0,0\rangle$	$\lvert^3P;0,-1\rangle$
	-1	$\lvert^3P;-1,1\rangle$	$\lvert^3P;-1,0\rangle\lvert^1D;-1,0\rangle$	$\lvert^3P;-1,-1\rangle$
	-2		$\lvert^1D;-2,0\rangle$	

(e) (0.5) Determine all LS terms possible for two *equivalent* p holes.
Answer: The best way is to analyze Selenium as an atom with a hole configuration $4p^2$[Kr]. Two *non-equivalent* p holes (and further only closed shells) correspond to an angular momentum Hilbert space of dimension $(2s+1)^2(2l+1)^2 = 6^2 = 36$. Combining the orbital angular momenta vectorially yields for all possible total orbital angular momentum values $L = 0, 1, 2$ and for the total spin $S = 0, 1$. This corresponds to 9 LS terms of the singlet type and 27 of the triplet type, together again 36 states:

p^2 coupled		L 0	1	2	degeneracy 36
S	0	$^1\mathrm{S}_0$	$^1\mathrm{P}_1$	$^1\mathrm{D}_2$	9
	1	$^3\mathrm{S}_1$	$\mathrm{P}_{0,1,2}$	$^3\mathrm{D}_{1,2,3}$	27

In this case we search for

$$\binom{6}{2} = \frac{6!}{2!4!} = \frac{6\times 5}{2} = 15$$

nonzero terms:

M_S	M_L	Slater determinants		LS terms			degeneracy
		Pauli allowed:		options	accepted	excl.	15
1	2	↿↿ − −	0	^{3}D	–	^{3}D	
	1	↿ ↿ −	1	^{3}P	^{3}P	-	9
	0	↿ − ↿, − ↿↿ −	1	^{3}P,^{3}S	-	^{3}S	
0	2	↿⇂ − −	1	^{1}D	^{1}D	-	5
	1	↿ ⇂ − (2×)	2	^{3}P,^{1}D,^{1}P	-	^{1}P	
	0	↿ − ⇂ (2×), − ↿⇂ −	3	^{3}P,^{1}D,^{1}S	^{1}S	-	1

Note that we found the same LS Terms. The corresponding Slater determinants are:

np^2		M_S		
uncoupled		1	0	-1
M_L	2		$\lvert\dot{1},\bar{1}\rangle$	
	1	$\lvert\dot{1},\dot{0}\rangle$	$\lvert\dot{1},\bar{0}\rangle\lvert\bar{1},\dot{0}\rangle$	$\lvert\bar{1},\bar{0}\rangle$
	0	$\lvert\dot{1},-\dot{1}\rangle$	$\lvert\dot{1},-\bar{1}\rangle\lvert\dot{0},\bar{0}\rangle\lvert\bar{1},-\dot{1}\rangle$	$\lvert\bar{1},-\bar{1}\rangle$
	-1	$\lvert\dot{0},-\dot{1}\rangle$	$\lvert\dot{0},-\bar{1}\rangle\lvert\bar{0},-\dot{1}\rangle$	$\lvert\bar{0},-\bar{1}\rangle$
	-2		$\lvert-\dot{1},-\bar{1}\rangle$	

Or, equivalently, *again* (as for for equivalent electrons)

$\lvert{}^{2S+1}L;M_L,M_S\rangle$		M_S		
uncoupled		1	0	-1
M_L	2		$\lvert{}^1D;2,0\rangle$	
	1	$\lvert{}^3P;1,1\rangle$	$\lvert{}^3P;1,0\rangle\lvert{}^1D;1,0\rangle$	$\lvert{}^3P;1,-1\rangle$
	0	$\lvert{}^3P;0,1\rangle$	$\lvert{}^3P;0,0\rangle\lvert{}^1S;0,0\rangle\lvert{}^1D;0,0\rangle$	$\lvert{}^3P;0,-1\rangle$
	-1	$\lvert{}^3P;-1,1\rangle$	$\lvert{}^3P;-1,0\rangle\lvert{}^1D;-1,0\rangle$	$\lvert{}^3P;-1,-1\rangle$
	-2		$\lvert{}^1D;-2,0\rangle$	

(f) (1.0) Give an expression for the Coulomb repulsion (screening) energy of the two equivalent holes and four valence electrons for each of the LS terms and demonstrate that these are the same.
Hint: Use Table 7.1 and expressions for determinantal matrix elements.
Answer A: Because all the sublevels of a given LS manifold are degenerate we can use the most convenient one to calculate the Coulomb energy. These are the sublevels represented by a single Slater determinant; hence, $|{}^3P;1,1\rangle = |\dot{1},\dot{0}\rangle_{5p^2}$, $|{}^1D;2,0\rangle = |\dot{1},\bar{1}\rangle_{5p^2}$. Unfortunately this is not possible for the ${}^1S$ term. To determine the Coulomb energy for this case we use the Slater sum rule.

i. ${}^3P$ term: $E({}^3P) = \langle\dot{1},\dot{0}|1/\rho_{12}|\dot{1},\dot{0}\rangle_{np^2}$. This is a diagonal matrix element of a two-body operator:

$$E({}^3P) = (p_1,p_0|1/\rho_{12}|p_1,p_0) - (p_0,p_1|1/\rho_{12}|p_1,p_0) = \mathcal{J} - \mathcal{K}, \tag{Q.14}$$

where $\mathcal{J} = (p_1,p_0|1/\rho_{12}|p_1,p_0)$ and $\mathcal{K} = (p_0,p_1|1/\rho_{12}|p_1,p_0)$ are the Coulomb integrals. As we are dealing with equivalent electrons we have $F^k = G^k$ and Eq. (Q.14) reduces to

$$E({}^3P) = \sum_{k=0,2}\left[a^k(p_1,p_0) - b^k(p_1,p_0)\right]F^k(np^2).$$

Substituting the values for $a^k(p_1,p_0)$ and $b^k(p_1,p_0)$ for $k=0,2$ from the Table the electrostatic repulsion can be written as the sum of two F integrals,

$$E({}^3P) = F_0 - 2F_2 - 3G_2 = F_0 - 5F_2 \tag{Q.15}$$

with respect to the energy of the [Kr] *configuration.* In accordance with convention the common denominators of the a^k and b^k coefficients where eliminated by redefining the F integrals: $F_0 \equiv F^0$, $F_2 \equiv F^2/25$.

ii. ${}^1D$ term: $E({}^1D) = \langle\dot{1},\bar{1}|\frac{1}{\rho_{12}}|\dot{1},\bar{1}\rangle_{np^2}$. This case is even simpler than the ${}^3P$ term because the exchange term vanishes; as the orbital part is fully stretched it is manifestly symmetric - note also the antisymmetric spin part. Looking up $a^k(p_1,p_1)$ for $k=0,2$ from the Table the expression for the electrostatic repulsion takes the form

$$E({}^1D) = \sum_{k=0,2} a^k(p_1,p_1)F^k(np^2) = F_0 + F_2 \tag{Q.16}$$

with respect to the energy of the [Kr] *configuration.*

iii. ^1S term: for this term we use the Slater sum rule. On the one hand we have

$$\mathrm{Tr}(3\times 3) = E(^3P) + E(^1D) + E(^1S) = 2F_0 - 4F_2 + E(^1S), \tag{Q.17}$$

where we used the independence of the LS term energies on M_S and M_L. The same subspace is spanned by the determinantal states $|\dot{0},\bar{0}\rangle_{np^2}$, $|\dot{1},-\bar{1}\rangle_{np^2}$ and $|\bar{1},-\dot{1}\rangle_{np^2}$. The trace of the corresponding matrix is given by

$$\begin{aligned}\mathrm{Tr}(3\times 3) &= \langle \dot{0},\bar{0}|\rho_{12}^{-1}|\dot{0},\bar{0}\rangle_{np^2} + \langle \dot{1},-\bar{1}|\rho_{12}^{-1}|\dot{1},-\bar{1}\rangle_{np^2} + \langle \bar{1},-\dot{1}|\rho_{12}^{-1}|\bar{1},-\dot{1}\rangle_{np^2}\\ &= (p_0,p_0|\rho_{12}^{-1}|p_0,p_0) + (p_1,p_{-1}|\rho_{12}^{-1}|p_1,p_{-1}) + (p_1,p_{-1}|\rho_{12}^{-1}|p_1,p_{-1})\\ &= (F_0+4F_2) + (F_0+F_2) + (F_0+F_2) = 3F_0 + 6F_2. \end{aligned}\tag{Q.18}$$

Here the three matrix elements were calculated by looking up the a^k terms with the aid of the Table. The exchange terms vanish because the holes are in different spin states. Comparing Eqs. (Q.17) and (Q.18), we find

$$E(^1S) = F_0 + 10F_2 \tag{Q.19}$$

with respect to the energy of the [Kr] *configuration.* We calculate for the *energy differences*: $E(^1D) - E(^3P) = 6F_2 > 0$ and $E(^1S) - E(^3P) = 15F_2 > 0$.

(g) (f) *Answer B:* We show the result for the four electron configuration. This is a lot of work (and *not* recommended) but yields the same result - as it should:

i. ^3P term: $E(^3P) = \langle \dot{1},\bar{1},\dot{0},-\dot{1}|1/\rho_{12}|\dot{1},\bar{1},\dot{0},-\dot{1}\rangle_{5p^4}$. This is a diagonal matrix element of a two-body operator:

$$E\left(^3P\right) = \frac{1}{2}\sum_{\kappa,\kappa'=1}^{4}{}'\left[(m_l^\kappa, m_l^{\kappa'}|\rho_{12}^{-1}|m_l^\kappa, m_l^{\kappa'}) - (m_l^\kappa, m_l^{\kappa'}|\rho_{12}^{-1}|m_l^{\kappa'}, m_l^\kappa)\right].$$

Thus we find:

$$\begin{aligned}E(^3P) = {}&(p_1,p_1|\rho_{12}^{-1}|p_1,p_1)\\ &+ (p_1,p_0|\rho_{12}^{-1}|p_1,p_0) - (p_0,p_1|\rho_{12}^{-1}|p_1,p_0)\\ &+ (p_1,p_{-1}|\rho_{12}^{-1}|p_1,p_{-1}) - (p_{-1},p_1|\rho_{12}^{-1}|p_1,p_{-1})\\ &+ (p_1,p_0|\rho_{12}^{-1}|p_1,p_0)\\ &+ (p_1,p_{-1}|\rho_{12}^{-1}|p_1,p_{-1})\\ &+ (p_0,p_{-1}|\rho_{12}^{-1}|p_0,p_{-1}) - (p_{-1},p_0|\rho_{12}^{-1}|p_0,p_{-1}).\end{aligned}$$

After simplification:

$$\begin{aligned}E(^3P) = {}&(p_1,p_1|\rho_{12}^{-1}|p_1,p_1)\\ &+ 2(p_1,p_0|\rho_{12}^{-1}|p_1,p_0) - (p_0,p_1|\rho_{12}^{-1}|p_1,p_0)\\ &+ 2(p_1,p_{-1}|\rho_{12}^{-1}|p_1,p_{-1}) - (p_{-1},p_1|\rho_{12}^{-1}|p_1,p_{-1})\\ &+ (p_0,p_{-1}|\rho_{12}^{-1}|p_0,p_{-1}) - (p_{-1},p_0|\rho_{12}^{-1}|p_0,p_{-1}).\end{aligned}$$

Using the table this becomes:

$$\begin{aligned}E(^3P) = {}&F_0 + F_2\\ &+ 2(F_0 - 2F_2) - 3F_2\\ &+ 2(F_0 + F_2) - 6F_2\\ &+ (F_0 - 2F_2) - 3F_2 = 6F_0 - 15F_2\end{aligned}$$

with respect to the energy of the [Zn] *configuration.* In accordance with convention the common denominators of the a^k and b^k coefficients where eliminated by redefining the F integrals: $F_0 \equiv F^0$, $F_2 \equiv F^2/25$.

ii. ${}^1D$ term: $E({}^1D) = \langle \dot{1}, \bar{1}, \dot{0}, \bar{0} | \frac{1}{\rho_{12}} | \dot{1}, \bar{1}, \dot{0}, \bar{0} \rangle_{5p^4}$. In this case we have:

$$\begin{aligned} E({}^1D) &= (p_1, p_1|\rho_{12}^{-1}|p_1, p_1) \\ &+ (p_1, p_0|\rho_{12}^{-1}|p_1, p_0) - (p_0, p_1|\rho_{12}^{-1}|p_1, p_0) \\ &+ (p_1, p_0|\rho_{12}^{-1}|p_1, p_0) \\ &+ (p_1, p_0|\rho_{12}^{-1}|p_1, p_0) \\ &+ (p_1, p_0|\rho_{12}^{-1}|p_1, p_0) - (p_0, p_1|\rho_{12}^{-1}|p_1, p_0) \\ &+ (p_0, p_0|\rho_{12}^{-1}|p_0, p_0). \end{aligned}$$

After simplification:

$$\begin{aligned} E({}^1D) &= (p_1, p_1|\rho_{12}^{-1}|p_1, p_1) \\ &+ 4(p_1, p_0|\rho_{12}^{-1}|p_1, p_0) - 2(p_0, p_1|\rho_{12}^{-1}|p_1, p_0) \\ &+ (p_0, p_0|\rho_{12}^{-1}|p_0, p_0). \end{aligned}$$

Using the table this becomes:

$$\begin{aligned} E({}^1D) &= F_0 + F_2 \\ &+ 4(F_0 - 2F_2) - 2(3F_2) \\ &+ (F_0 + 4F_2) = 6F_0 - 9F_2 \end{aligned}$$

with respect to the energy of the [Zn] *configuration*; in accordance with convention the common denominators of the a^k and b^k coefficients where eliminated by redefining the F integrals: $F_0 \equiv F^0$, $F_2 \equiv F^2/25$.

iii. ${}^1S$ term: for this term we use the Slater sum rule. On the one hand we have

$$\mathrm{Tr}(3 \times 3) = E({}^3P) + E({}^1D) + E({}^1S) = 12F_0 - 24F_2 + E({}^1S),$$

where we used the independence of the LS term energies on M_S and M_L. The same subspace is spanned by the determinantal states $|\dot{1}, \dot{0}, \bar{0}, -\bar{1}\rangle_{5p^4}$, $|\dot{1}, \bar{1}, -\dot{1}, -\bar{1}\rangle_{5p^4}$ and $|\bar{1}, \dot{0}, \bar{0}, -\dot{1}\rangle_{5p^4}$. The trace of the corresponding matrix is given by

$$\begin{aligned} \mathrm{Tr}(3 \times 3) = &\langle \dot{1}, \dot{0}, \bar{0}, -\bar{1}|\rho_{12}^{-1}|\dot{1}, \dot{0}, \bar{0}, -\bar{1}\rangle_{5p^4} \\ &+ \langle \dot{1}, \bar{1}, -\dot{1}, -\bar{1}|\rho_{12}^{-1}|\dot{1}, \bar{1}, -\dot{1}, -\bar{1}\rangle_{5p^4} + \langle \bar{1}, \dot{0}, \bar{0}, -\dot{1}|\rho_{12}^{-1}|\bar{1}, \dot{0}, \bar{0}, -\dot{1}\rangle_{5p^4}. \end{aligned}$$

The *first* matrix element can be expressed as

$$\begin{aligned} \langle \dot{1}, \dot{0}, \bar{0}, -\bar{1}|\frac{1}{\rho_{12}}|\dot{1}, \dot{0}, \bar{0}, -\bar{1}\rangle &= (p_1, p_0|\rho_{12}^{-1}|p_1, p_0) - (p_0, p_1|\rho_{12}^{-1}|p_1, p_0) \\ &+ (p_1, p_0|\rho_{12}^{-1}|p_1, p_0) \\ &+ (p_1, p_{-1}|\rho_{12}^{-1}|p_1, p_{-1}) \\ &+ (p_0, p_0|\rho_{12}^{-1}|p_0, p_0) \\ &+ (p_0, p_{-1}|\rho_{12}^{-1}|p_0, p_{-1}) \\ &+ (p_0, p_{-1}|\rho_{12}^{-1}|p_0, p_{-1}) - (p_{-1}, p_0|\rho_{12}^{-1}|p_0, p_{-1}). \end{aligned}$$

The *second* matrix element can be expressed as

$$\begin{aligned}\langle\bar{1},\dot{0},\bar{0},-\dot{1}|\frac{1}{\rho_{12}}|\bar{1},\dot{0},\bar{0},-\dot{1}\rangle = &(p_1,p_0|\rho_{12}^{-1}|p_1,p_0)\\ &+(p_1,p_0|\rho_{12}^{-1}|p_1,p_0)-(p_0,p_1|\rho_{12}^{-1}|p_1,p_0)\\ &+(p_1,p_{-1}|\rho_{12}^{-1}|p_1,p_{-1})\\ &+(p_0,p_0|\rho_{12}^{-1}|p_0,p_0)\\ &+(p_0,p_{-1}|\rho_{12}^{-1}|p_0,p_{-1})-(p_{-1},p_0|\rho_{12}^{-1}|p_0,p_{-1})\\ &+(p_0,p_{-1}|\rho_{12}^{-1}|p_0,p_{-1}).\end{aligned}$$

The *third* matrix element can be expressed as

$$\begin{aligned}\langle\dot{1},\bar{1},-\dot{1},-\bar{1}|\frac{1}{\rho_{12}}|\dot{1},\bar{1},-\dot{1},-\bar{1}\rangle = &(p_1,p_1|\rho_{12}^{-1}|p_1,p_1)\\ &+(p_1,p_{-1}|\rho_{12}^{-1}|p_1,p_{-1})-(p_{-1},p_1|\rho_{12}^{-1}|p_1,p_{-1})\\ &+(p_1,p_{-1}|\rho_{12}^{-1}|p_1,p_{-1})\\ &+(p_1,p_{-1}|\rho_{12}^{-1}|p_1,p_{-1})\\ &+(p_1,p_{-1}|\rho_{12}^{-1}|p_1,p_{-1})-(p_{-1},p_1|\rho_{12}^{-1}|p_1,p_{-1})\\ &+(p_{-1},p_{-1}|\rho_{12}^{-1}|p_{-1},p_{-1}).\end{aligned}$$

Together this becomes:

$$\begin{aligned}\mathrm{Tr}(3\times 3) = &(p_1,p_1|\rho_{12}^{-1}|p_1,p_1)\\ &+4(p_1,p_0|\rho_{12}^{-1}|p_1,p_0)-2(p_0,p_1|\rho_{12}^{-1}|p_1,p_0)\\ &+6(p_1,p_{-1}|\rho_{12}^{-1}|p_1,p_{-1})-2(p_{-1},p_1|\rho_{12}^{-1}|p_1,p_{-1})\\ &+2(p_0,p_0|\rho_{12}^{-1}|p_0,p_0)\\ &+4(p_0,p_{-1}|\rho_{12}^{-1}|p_0,p_{-1})-2(p_{-1},p_0|\rho_{12}^{-1}|p_0,p_{-1})\\ &+(p_{-1},p_{-1}|\rho_{12}^{-1}|p_{-1},p_{-1}).\end{aligned}$$

Next we express these matrix elements in terms of the Coulomb integrals:*

$$\begin{aligned}\mathrm{Tr}(3\times 3) = &(F_0+F_2)\\ &+4(F_0-2F_2)-2(3F_2)\\ &+6(F_0+F_2)-2(6F_2)\\ &+2(F_0+4F_2)\\ &+4(F_0-2F_2)-2(3F_2)\\ &+(F_0+F_2)=18F_0-24F_2.\end{aligned}$$

We determine these matrix elements by looking up the a^k and b^k terms with the aid of the Table. Note that the exchange terms are zero whenever the electrons differ in spin.

$$E(^1S)=\mathrm{Tr}(3\times 3)-12F_0+24F_2=6F_0 \tag{Q.20}$$

with respect to the energy of the [Zn] *configuration.* We calculate for the *energy differences*: $E(^1D)-E(^3P)=6F_2>0$ and $E(^1S)-E(^3P)=15F_2>0$. Note that these *differences* coincide with values obtained above.

Q.23 Problem set 12

PROBLEMS CHAPTER 10 (CONTINUED)

Equivalence of electrons and holes

(1.0) Consider a closed shell with one vacancy. Let the orbital and spin angular momentum of the electron that can fill the vacancy be given by $\boldsymbol{l}$ and $\boldsymbol{s}$, respectively.

1. (0.1) Give the expression for the angular momentum operator of an object of mass m_h, p0osition $\mathbf{r}$ and velocity $\mathbf{v}_h$ with respect to the nucleus of infinite mass.
2. (0.1) Give the expression for the orbital magnetic moment operator of a hole, $\boldsymbol{\mu}^{(h)}$, as an object of charge q, mass m_h and (positive) g-factor g_h.
3. (0.1) What are the orbital ($\boldsymbol{l}_h$) and spin ($\boldsymbol{s}_h$) angular momentum of the hole?
4. (0.1) What is the mass of the hole (m_h) as compared to that of the vacant electron?
5. (0.1) What are the orbital $\mathbf{L}$ and spin $\mathbf{S}$ angular momentum of the shell with one vacancy?
6. (0.1) What is the velocity of the hole ($\mathbf{v}_h$) as compared to that of the vacant electron?
7. (0.1) What is spin magnetic moment of the hole as compared to that of the vacant electron?
8. (0.1) Are the g factors of electron and hole the same?
9. (0.2) Give the expression for the spin-orbit shift caused by the hole.

Q.24 Problem set 12 -solutions

Solutions Problems Chapter 10 (continued)

Equivalence of electrons and holes

(1.0) Consider a closed shell with one vacancy. Let the orbital and spin angular momentum of the electron that can fill the vacancy be given by $\boldsymbol{l}$ and $\boldsymbol{s}$, respectively.

1. (0.1) The expression for the angular momentum operator is $\boldsymbol{l}_h = m_h(\mathbf{r} \times \mathbf{v}_h)$.
2. (0.1) The expression for the orbital moment operator is $\boldsymbol{\mu}_l^{(h)} = g_h(q/2m_h)\boldsymbol{l}_h$.
3. (0.1) The orbital and spin angular momentum of the hole are $\boldsymbol{l}_h = -\boldsymbol{l}$, $\boldsymbol{s}_h = -\boldsymbol{s}$.
4. (0.1) The mass of the hole is $m_h = -m_e$.
5. (0.1) The orbital $\mathbf{L}$ and spin $\mathbf{S}$ angular momentum of the shell with one vacancy are $\mathbf{L} = -\boldsymbol{l}$, $\mathbf{S} = -\boldsymbol{s}$.
6. (0.1) The velocity of the hole as compared to that of the vacant electron is $\mathbf{v}_h = \mathbf{v}_e$.
7. (0.1) The spin magnetic moment of the hole is $\boldsymbol{\mu}_h = g_e(e/2m_e)\boldsymbol{s}$.
8. (0.1) The g factors of electron and hole must be the same to assure that the magnetic moments add up to zero $\boldsymbol{\mu}_h = -\boldsymbol{\mu}_e$ and $\boldsymbol{\mu}_l^{(h)} = -\boldsymbol{\mu}_l^{(e)}$.
9. (0.2) The expression for the spin-orbit shift is

$$\Delta E_{n,J}^{LS} = -\left(\zeta_{nl}/\hbar^2\right)\langle nLSJM_J|\mathbf{L}\cdot\mathbf{S}|nLSJM_J\rangle,$$

where $\zeta_{nl} = \langle nl||\xi(r)||nl\rangle\hbar^2 > 0$. Using the inner product rule $\mathbf{L}\cdot\mathbf{S} = \frac{1}{2}[\mathbf{J}^2 - \mathbf{L}^2 - \mathbf{S}^2]$ we obtain

$$\Delta E_{n,J}^{LS} = -\frac{1}{2}\zeta_{nl}[J\,(J+1) - L(L+1) - S(S+1)].$$
